This is useful for Arabic, Hebrew and many other languages where one may have combining characters overtop of base characters, and want to remove only the combining ones.

**NOTE:** This option is reset when **'compatible'** is set.

**'dictionary' 'dict'** string (default "")  
global or local to buffer **global-local**  
List of file names, separated by commas, that are used to lookup words for keyword completion commands **i\_CTRL-X\_CTRL-K**. Each file should contain a list of words. This can be one word per line, or several words per line, separated by non-keyword characters (white space is preferred). Maximum line length is 510 bytes.

When this option is empty or an entry "spell" is present, and spell checking is enabled, words in the word lists for the currently active **'spelllang'** are used. See **spell**.

To include a comma in a file name precede it with a backslash. Spaces after a comma are ignored, otherwise spaces are included in the file name. See **option-backslash** about using backslashes.

This has nothing to do with the **Dictionary** variable type.

Where to find a list of words?

- On FreeBSD, there is the file "/usr/share/dict/words".
- In the Simtel archive, look in the "msdos/linguist" directory.
- In "miscfiles" of the GNU collection.

The use of **:set+=** and **:set-=** is preferred when adding or removing directories from the list. This avoids problems when a future version uses another default.

Backticks cannot be used in this option for security reasons.

**'diff'** boolean (default off)  
local to window  
{not available when compiled without the **+diff** feature}  
Join the current window in the group of windows that shows differences between files. See **vimdiff**.

**'diffexpr' 'dex'** string (default "")  
global  
{not available when compiled without the **+diff** feature}  
Expression which is evaluated to obtain a diff file (either ed-style or unified-style) from two versions of a file. See **diff-diffexpr**. This option cannot be set from a **modeline** or in the **sandbox**, for security reasons.

**'diffopt' 'dip'** string (default "internal,filler,closeoff")  
global  
{not available when compiled without the **+diff** feature}

Option settings for diff mode. It can consist of the following items. All are optional. Items must be separated by a comma.

- `algorithm:{text}` Use the specified diff algorithm with the internal diff engine. Currently supported algorithms are:
- `myers` the default algorithm
  - `minimal` spend extra time to generate the smallest possible diff
  - `patience` patience diff algorithm
  - `histogram` histogram diff algorithm
- `closeoff` When a window is closed where `'diff'` is set and there is only one window remaining in the same tab page with `'diff'` set, execute `':diffoff'` in that window. This undoes a `':diffsplit'` command.
- `context:{n}` Use a context of `{n}` lines between a change and a fold that contains unchanged lines. When omitted a context of six lines is used. When using zero the context is actually one, since folds require a line in between, also for a deleted line. Set it to a very large value (999999) to disable folding completely. See `fold-diff`.
- `filler` Show filler lines, to keep the text synchronized with a window that has inserted lines at the same position. Mostly useful when windows are side-by-side and `'scrollbind'` is set.
- `foldcolumn:{n}` Set the `'foldcolumn'` option to `{n}` when starting diff mode. Without this 2 is used.
- `followwrap` Follow the `'wrap'` option and leave as it is.
- `horizontal` Start diff mode with horizontal splits (unless explicitly specified otherwise).
- `hiddenoff` Do not use diff mode for a buffer when it becomes hidden.
- `iblack` Ignore changes where lines are all blank. Adds the `"-B"` flag to the `"diff"` command if `'diffexpr'` is empty. Check the documentation of the `"diff"` command for what this does exactly.  
**NOTE:** the diff windows will get out of sync, because no differences between blank lines are taken into account.
- `icase` Ignore changes in case of text. `"a"` and `"A"`

are considered the same. Adds the "-i" flag to the "diff" command if **'diffexpr'** is empty.

indent-heuristic	Use the indent heuristic for the internal diff library.
internal	Use the internal diff library. This is ignored when <b>'diffexpr'</b> is set. <b>E960</b> When running out of memory when writing a buffer this item will be ignored for diffs involving that buffer. Set the <b>'verbose'</b> option to see when this happens.
iwhite	Ignore changes in amount of white space. Adds the "-b" flag to the "diff" command if <b>'diffexpr'</b> is empty. Check the documentation of the "diff" command for what this does exactly. It should ignore adding trailing white space, but not leading white space.
iwhiteall	Ignore all white space changes. Adds the "-w" flag to the "diff" command if <b>'diffexpr'</b> is empty. Check the documentation of the "diff" command for what this does exactly.
iwhiteeol	Ignore white space changes at end of line. Adds the "-Z" flag to the "diff" command if <b>'diffexpr'</b> is empty. Check the documentation of the "diff" command for what this does exactly.
linematch:{n}	Align and mark changes between the most similar lines between the buffers. When the total number of lines in the diff hunk exceeds {n}, the lines will not be aligned because for very large diff hunks there will be a noticeable lag. A reasonable setting is "linematch:60", as this will enable alignment for a 2 buffer diff hunk of 30 lines each, or a 3 buffer diff hunk of 20 lines each.
vertical	Start diff mode with vertical splits (unless explicitly specified otherwise).

Examples:

```
:set diffopt=internal,filler,context:4
:set diffopt=
:set diffopt=internal,filler,foldcolumn:3
:set diffopt-=internal " do NOT use the internal diff parser
```

**'digraph'** **'dg'** **'digraph'** **'dg'** **'nodigraph'** **'nodg'**  
boolean (default off)

global  
{not available when compiled without the `+digraphs`  
feature}

Enable the entering of digraphs in Insert mode with `{char1} <BS> {char2}`. See `digraphs` .

**NOTE:** This option is reset when `'compatible'` is set.

`'directory' 'dir'` string (default for Amiga: `".,t:"`,  
for Win32: `".,$TEMP,c:\tmp,c:\temp"`  
for Unix: `".,~/tmp,/var/tmp,/tmp"`)  
global

List of directory names for the swap file, separated with commas.  
Recommended value: `".,~/vimswap/"` - this will put the swap file next  
to the edited file if possible, and in your personal swap directory  
otherwise. Make sure `"~/vimswap/"` is only readable for you.

Possible items:

- The swap file will be created in the first directory where this is possible.
- Empty means that no swap file will be used (recovery is impossible!) and no `E303` error will be given.
- A directory `."` means to put the swap file in the same directory as the edited file. On Unix, a dot is prepended to the file name, so it doesn't show in a directory listing. On MS-Windows the "hidden" attribute is set and a dot prepended if possible.
- A directory starting with `"/"` (or `\"` for MS-Windows) means to put the swap file relative to where the edited file is. The leading `."` is replaced with the path name of the edited file.
- For Unix and Win32, if a directory ends in two path separators `"/"/`, the swap file name will be built from the complete path to the file with all path separators replaced by percent `'%'` signs (including the colon following the drive letter on Win32). This will ensure file name uniqueness in the preserve directory.  
On Win32, it is also possible to end with `\"`. However, when a separating comma is following, you must use `"/"/`, since `\"` will include the comma in the file name. Therefore it is recommended to use `'/'`, instead of `\"`.
- Spaces after the comma are ignored, other spaces are considered part of the directory name. To have a space at the start of a directory name, precede it with a backslash.
- To include a comma in a directory name precede it with a backslash.
- A directory name may end in an `':'` or `'/'`.
- Environment variables are expanded `:set_env` .
- Careful with `'\"` characters, type one before a space, type two to get one in the option (see `option-backslash` ), for example:  
`:set dir=c:\\tmp,\\ dir\\,with\\,commas,\\ \\ dir \\ with \\ spaces`
- For backwards compatibility with `Vim version 3.0` a `'>'` at the start of the option is removed.

Using `."` first in the list is recommended. This means that editing the same file twice will result in a warning. Using `"/tmp"` on Unix is discouraged: When the system crashes you lose the swap file.

`"/var/tmp"` is often not cleared when rebooting, thus is a better choice than `"/tmp"`. But others on the computer may be able to see the

files, and it can contain a lot of files, your swap files get lost in the crowd. That is why a "tmp" directory in your home directory is tried first.

The use of `:set+=` and `:set-=` is preferred when adding or removing directories from the list. This avoids problems when a future version uses another default.

This option cannot be set from a `modeline` or in the `sandbox`, for security reasons.

**'display' 'dy'** string (default "", set to "truncate" in `defaults.vim`)  
global

Change the way text is displayed. This is a comma-separated list of flags:

lastline When included, as much as possible of the last line in a window will be displayed. "===" is put in the last columns of the last screen line to indicate the rest of the line is not displayed.

truncate Like "lastline", but "===" is displayed in the first column of the last screen line. Overrides "lastline".

uhex Show unprintable characters hexadecimal as <xx> instead of using ^C and ~C.

When neither "lastline" nor "truncate" is included, a last line that doesn't fit is replaced with "@" lines.

The "@" character can be changed by setting the "lastline" item in **'fillchars'**. The character is highlighted with `hl-NonText`.

**'eadirection' 'ead'** string (default "both")  
global

Tells when the **'equalalways'** option applies:

ver vertically, width of windows is not affected

hor horizontally, height of windows is not affected

both width and height of windows is affected

**'edcompatible' 'ed'** boolean (default off)  
global

Makes the 'g' and 'c' flags of the ":substitute" command to be toggled each time the flag is given. See `complex-change`. See also **'gdefault'** option.

Switching this option on may break plugins!

This option is not used in `Vim9` script.

**'emoji' 'emo'** boolean (default: on)  
global

When on all Unicode emoji characters are considered to be full width. This excludes "text emoji" characters, which are normally displayed as single width. Unfortunately there is no good specification for this and it has been determined on trial-and-error basis. Use the

`setcellwidths()` function to change the behavior.

```
'encoding' 'enc' 'encoding' 'enc' E543
 string (default for MS-Windows: "utf-8",
 otherwise: value from $LANG or "latin1")
 global
```

Sets the character encoding used inside Vim. It applies to text in the buffers, registers, Strings in expressions, text stored in the viminfo file, etc. It sets the kind of characters which Vim can work with. See [encoding-names](#) for the possible values.

**NOTE:** Changing this option will not change the encoding of the existing text in Vim. It may cause non-ASCII text to become invalid. It should normally be kept at its default value, or set when Vim starts up. See [multibyte](#) . To reload the menus see `:menutrans` .

This option cannot be set from a [modeline](#) . It would most likely corrupt the text.

**NOTE:** For GTK+ 2 or later, it is highly recommended to set `'encoding'` to "utf-8". Although care has been taken to allow different values of `'encoding'`, "utf-8" is the natural choice for the environment and avoids unnecessary conversion overhead. "utf-8" has not been made the default to prevent different behavior of the GUI and terminal versions, and to avoid changing the encoding of newly created files without your knowledge (in case `'fileencodings'` is empty).

The character encoding of files can be different from `'encoding'`. This is specified with `'fileencoding'`. The conversion is done with `iconv()` or as specified with `'charconvert'`.

If you need to know whether `'encoding'` is a multibyte encoding, you can use:

```
if has("multi_byte_encoding")
```

Normally `'encoding'` will be equal to your current locale. This will be the default if Vim recognizes your environment settings. If `'encoding'` is not set to the current locale, `'termencoding'` must be set to convert typed and displayed text. See [encoding-table](#) .

When you set this option, it fires the `EncodingChanged` autocommand event so that you can set up fonts if necessary.

When the option is set, the value is converted to lowercase. Thus you can set it with uppercase values too. Underscores are translated to '-' signs.

When the encoding is recognized, it is changed to the standard name. For example "Latin-1" becomes "latin1", "ISO\_88592" becomes "iso-8859-2" and "utf8" becomes "utf-8".

**Note:** "latin1" is also used when the encoding could not be detected. This only works when editing files in the same encoding! When the actual character set is not latin1, make sure `'fileencoding'` and `'fileencodings'` are empty. When conversion is needed, switch to using

utf-8.

When "unicode", "ucs-2" or "ucs-4" is used, Vim internally uses utf-8. You don't notice this while editing, but it does matter for the `viminfo-file`. And Vim expects the terminal to use utf-8 too. Thus setting `'encoding'` to one of these values instead of utf-8 only has effect for encoding used for files when `'fileencoding'` is empty.

When `'encoding'` is set to a Unicode encoding, and `'fileencodings'` was not set yet, the default for `'fileencodings'` is changed.

`'endoffile' 'eof'` `'endoffile' 'eof' 'noendoffile' 'noeof'`  
boolean (default off)  
local to buffer

Indicates that a **CTRL-Z** character was found at the end of the file when reading it. Normally only happens when `'fileformat'` is "dos". When writing a file and this option is off and the `'binary'` option is on, or `'fixeol'` option is off, no **CTRL-Z** will be written at the end of the file.

See `eol-and-eof` for example settings.

`'endofline' 'eol'` `'endofline' 'eol' 'noendofline' 'noeol'`  
boolean (default on)  
local to buffer

When writing a file and this option is off and the `'binary'` option is on, or `'fixeol'` option is off, no `<EOL>` will be written for the last line in the file. This option is automatically set or reset when starting to edit a new file, depending on whether file has an `<EOL>` for the last line in the file. Normally you don't have to set or reset this option.

When `'binary'` is off and `'fixeol'` is on the value is not used when writing the file. When `'binary'` is on or `'fixeol'` is off it is used to remember the presence of a `<EOL>` for the last line in the file, so that when you write the file the situation from the original file can be kept. But you can change it if you want to.

See `eol-and-eof` for example settings.

`'equalalways' 'ea'` `'equalalways' 'ea' 'noequalalways' 'noea'`  
boolean (default on)  
global

When on, all the windows are automatically made the same size after splitting or closing a window. This also happens the moment the option is switched on. When off, splitting a window will reduce the size of the current window and leave the other windows the same. When closing a window the extra lines are given to the window next to it (depending on `'splitbelow'` and `'splitright'`).

When mixing vertically and horizontally split windows, a minimal size is computed and some windows may be larger if there is room. The `'eadirection'` option tells in which direction the size is affected. Changing the height and width of a window can be avoided by setting `'winfixheight'` and `'winfixwidth'`, respectively.

If a window size is specified when creating a new window sizes are currently not equalized (it's complicated, but may be implemented in the future).

**'equalprg' 'ep'** 'equalprg' 'ep'  
 string (default "")  
 global or local to buffer [global-local](#)  
 External program to use for "=" command. When this option is empty the internal formatting functions are used; either **'lisp'**, **'cindent'** or **'indentexpr'**. When Vim was compiled without internal formatting, the "indent" program is used.  
 Environment variables are expanded [:set\\_env](#) . See [option-backslash](#) about including spaces and backslashes.  
 This option cannot be set from a [modeline](#) or in the [sandbox](#) , for security reasons.

**'errorbells' 'eb'** 'errorbells' 'eb' 'noerrorbells' 'noeb'  
 boolean (default off)  
 global  
 Ring the bell (beep or screen flash) for error messages. This only makes a difference for error messages, the bell will be used always for a lot of errors without a message (e.g., hitting <Esc> in Normal mode). See **'visualbell'** on how to make the bell behave like a beep, screen flash or do nothing. See **'belloff'** to finetune when to ring the bell.

**'errorfile' 'ef'** 'errorfile' 'ef'  
 string (Amiga default: "AztecC.Err",  
 others: "errors.err")  
 global  
 {not available when compiled without the [+quickfix](#) feature}  
 Name of the errorfile for the QuickFix mode (see [:cf](#) ).  
 When the "-q" command-line argument is used, **'errorfile'** is set to the following argument. See [-q](#) .  
 NOT used for the ":make" command. See **'makeef'** for that.  
 Environment variables are expanded [:set\\_env](#) .  
 See [option-backslash](#) about including spaces and backslashes.  
 This option cannot be set from a [modeline](#) or in the [sandbox](#) , for security reasons.

**'errorformat' 'efm'** 'errorformat' 'efm'  
 string (default is very long)  
 global or local to buffer [global-local](#)  
 {not available when compiled without the [+quickfix](#) feature}  
 Scanf-like description of the format for the lines in the error file (see [errorformat](#) ).

**'esckey' 'ek'** 'esckey' 'ek' 'noesckey' 'noek'  
 boolean (Vim default: on, Vi default: off)  
 global  
 Function keys that start with an <Esc> are recognized in Insert mode. When this option is off, the cursor and function keys cannot be used in Insert mode if they start with an <Esc>. The advantage of this is that the single <Esc> is recognized immediately, instead of after one second. Instead of resetting this option, you might want to

try changing the values for `'timeoutlen'` and `'ttimeoutlen'`. Note that when `'esckeys'` is off, you can still map anything, but the cursor keys won't work by default.

**NOTE:** This option is set to the Vi default value when `'compatible'` is set and to the Vim default value when `'compatible'` is reset.

**NOTE:** when this option is off then the `modifyOtherKeys` and `xterm-bracketed-paste` functionality is disabled while in Insert mode to avoid ending Insert mode with any key that has a modifier.

`'eventignore'` `'ei'` string (default "")  
global

A list of autocommand event names, which are to be ignored. When set to "all" or when "all" is one of the items, all autocommand events are ignored, autocommands will not be executed. Otherwise this is a comma-separated list of event names. Example:  
`:set ei=WinEnter,WinLeave`

`'eventignorewin'` `'eiw'` string (default "")  
window-local

Similar to `'eventignore'` but applies to a particular window and its buffers, for which window and buffer related autocommands can be ignored indefinitely without affecting the global `'eventignore'`.

`'expandtab'` `'et'` boolean (default off)  
local to buffer

In Insert mode: Use the appropriate number of spaces to insert a `<Tab>`. Spaces are used in indents with the `'>'` and `'<'` commands and when `'autoindent'` is on. To insert a real tab when `'expandtab'` is on, use `CTRL-V<Tab>`. See also `:retab` and `ins-expandtab`. This option is reset when the `'paste'` option is set and restored when the `'paste'` option is reset.

**NOTE:** This option is reset when `'compatible'` is set.

`'execr'` `'ex'` boolean (default off)  
global

Enables the reading of `.vimrc`, `.execr` and `.gvimrc` in the current directory.

Setting this option is a potential security leak. E.g., consider unpacking a package or fetching files from github, a `.vimrc` in there might be a trojan horse. **BETTER NOT SET THIS OPTION!**

Instead, define an autocommand in your `.vimrc` to set options for a matching directory.

If you do switch this option on you should also consider setting the `'secure'` option (see `initialization`).

Also see `.vimrc` and `gui-init`.

This option cannot be set from a `modeline` or in the `sandbox`, for security reasons.

`'fileencoding'` `'fenc'` string (default: "")  
local to buffer

Sets the character encoding for the file of this buffer.

When `'fileencoding'` is different from `'encoding'`, conversion will be done when writing the file. For reading see below.

When `'fileencoding'` is empty, the same value as `'encoding'` will be used (no conversion when reading or writing a file).

No error will be given when the value is set, only when it is used, only when writing a file.

Conversion will also be done when `'encoding'` and `'fileencoding'` are both a Unicode encoding and `'fileencoding'` is not utf-8. That's because internally Unicode is always stored as utf-8.

WARNING: Conversion can cause loss of information! When `'encoding'` is "utf-8" or another Unicode encoding, conversion is most likely done in a way that the reverse conversion results in the same text. When `'encoding'` is not "utf-8" some characters may be lost!

See `'encoding'` for the possible values. Additionally, values may be specified that can be handled by the converter, see [mbyte-conversion](#).

When reading a file `'fileencoding'` will be set from `'fileencodings'`.

To read a file in a certain encoding it won't work by setting `'fileencoding'`, use the `++enc` argument. One exception: when `'fileencodings'` is empty the value of `'fileencoding'` is used.

For a new file the global value of `'fileencoding'` is used.

Prepending "8bit-" and "2byte-" has no meaning here, they are ignored. When the option is set, the value is converted to lowercase. Thus you can set it with uppercase values too. '\_' characters are replaced with '-'. If a name is recognized from the list for `'encoding'`, it is replaced by the standard name. For example "ISO8859-2" becomes "iso-8859-2".

When this option is set, after starting to edit a file, the `'modified'` option is set, because the file would be different when written.

Keep in mind that changing `'fenc'` from a modeline happens AFTER the text has been read, thus it applies to when the file will be written. If you do set `'fenc'` in a modeline, you might want to set `'nomodified'` to avoid not being able to ":q".

This option can not be changed when `'modifiable'` is off.

`'fe'`  
**NOTE:** Before version 6.0 this option specified the encoding for the whole of Vim, this was a mistake. Now use `'encoding'` instead. The old short name was `'fe'`, which is no longer used.

`'fileencodings'` `'fencs'` string (default: "ucs-bom",  
`'fileencodings'` `'fencs'`

"ucs-bom,utf-8,default,latin1" when  
'encoding' is set to a Unicode value)

global

This is a list of character encodings considered when starting to edit an existing file. When a file is read, Vim tries to use the first mentioned character encoding. If an error is detected, the next one in the list is tried. When an encoding is found that works, 'fileencoding' is set to it. If all fail, 'fileencoding' is set to an empty string, which means the value of 'encoding' is used.

WARNING: Conversion can cause loss of information! When 'encoding' is "utf-8" (or one of the other Unicode variants) conversion is most likely done in a way that the reverse conversion results in the same text. When 'encoding' is not "utf-8" some non-ASCII characters may be lost! You can use the ++bad argument to specify what is done with characters that can't be converted.

For an empty file or a file with only ASCII characters most encodings will work and the first entry of 'fileencodings' will be used (except "ucs-bom", which requires the BOM to be present). If you prefer another encoding use an BufReadPost autocommand event to test if your preferred encoding is to be used. Example:

```
au BufReadPost * if search('\S', 'w') == 0 |
 \ set fenc=iso-2022-jp | endif
```

This sets 'fileencoding' to "iso-2022-jp" if the file does not contain non-blank characters.

When the ++enc argument is used then the value of 'fileencodings' is not used.

Note that 'fileencodings' is not used for a new file, the global value of 'fileencoding' is used instead. You can set it with:

```
:setglobal fenc=iso-8859-2
```

This means that a non-existing file may get a different encoding than an empty file.

The special value "ucs-bom" can be used to check for a Unicode BOM (Byte Order Mark) at the start of the file. It must not be preceded by "utf-8" or another Unicode encoding for this to work properly. An entry for an 8-bit encoding (e.g., "latin1") should be the last, because Vim cannot detect an error, thus the encoding is always accepted.

The special value "default" can be used for the encoding from the environment. On MS-Windows this is the system encoding. Otherwise this is the default value for 'encoding'. It is useful when 'encoding' is set to "utf-8" and your environment uses a non-latin1 encoding, such as Russian.

When 'encoding' is "utf-8" and a file contains an illegal byte sequence it won't be recognized as UTF-8. You can use the 8g8 command to find the illegal byte sequence.

WRONG VALUES:

```
latin1,utf-8
utf-8,ucs-bom,latin1

cp1250,latin1
```

WHAT'S WRONG:

```
"latin1" will always be used
BOM won't be recognized in an utf-8
file
"cp1250" will always be used
```

If 'fileencodings' is empty, 'fileencoding' is not modified.

See 'fileencoding' for the possible values.

Setting this option does not have an effect until the next time a file

is read.

```
'fileformat' 'ff' 'fileformat' 'ff'
string (MS-Windows default: "dos",
 Unix default: "unix")
local to buffer
```

This gives the `<EOL>` of the current buffer, which is used for reading/writing the buffer from/to a file:

```
dos <CR><NL>
unix <NL>
mac <CR>
```

When "dos" is used, **CTRL-Z** at the end of a file is ignored.

See [file-formats](#) and [file-read](#).

For the character encoding of the file see ['fileencoding'](#).

When ['binary'](#) is set, the value of ['fileformat'](#) is ignored, file I/O works like it was set to "unix".

This option is set automatically when starting to edit a file and ['fileformats'](#) is not empty and ['binary'](#) is off.

When this option is set, after starting to edit a file, the ['modified'](#) option is set, because the file would be different when written.

This option can not be changed when ['modifiable'](#) is off.

For backwards compatibility: When this option is set to "dos", ['textmode'](#) is set, otherwise ['textmode'](#) is reset.

```
'fileformats' 'ffs' 'fileformats' 'ffs'
string (default:
 Vim+Vi MS-Windows: "dos,unix",
 Vim Unix: "unix,dos",
 Vi Cygwin: "unix,dos",
 Vi others: "")
global
```

This gives the end-of-line (`<EOL>`) formats that will be tried when starting to edit a new buffer and when reading a file into an existing buffer:

- When empty, the format defined with ['fileformat'](#) will be used always. It is not set automatically.
- When set to one name, that format will be used whenever a new buffer is opened. ['fileformat'](#) is set accordingly for that buffer. The ['fileformats'](#) name will be used when a file is read into an existing buffer, no matter what ['fileformat'](#) for that buffer is set to.
- When more than one name is present, separated by commas, automatic `<EOL>` detection will be done when reading a file. When starting to edit a file, a check is done for the `<EOL>`:
  1. If all lines end in `<CR><NL>`, and ['fileformats'](#) includes "dos", ['fileformat'](#) is set to "dos".
  2. If a `<NL>` is found and ['fileformats'](#) includes "unix", ['fileformat'](#) is set to "unix". **Note** that when a `<NL>` is found without a preceding `<CR>`, "unix" is preferred over "dos".
  3. If ['fileformat'](#) has not yet been set, and if a `<CR>` is found, and if ['fileformats'](#) includes "mac", ['fileformat'](#) is set to "mac".

This means that "mac" is only chosen when:

"unix" is not present or no `<NL>` is found in the file, and

"dos" is not present or no `<CR><NL>` is found in the file.

Except: if "unix" was chosen, but there is a `<CR>` before

the first <NL>, and there appear to be more <CR>s than <NL>s in the first few lines, "mac" is used.

4. If **'fileformat'** is still not set, the first name from **'fileformats'** is used.

When reading a file into an existing buffer, the same is done, but this happens like **'fileformat'** has been set appropriately for that file only, the option is not changed.

When **'binary'** is set, the value of **'fileformats'** is not used.

When Vim starts up with an empty buffer the first item is used. You can overrule this by setting **'fileformat'** in your .vimrc.

For systems with a Dos-like <EOL> (<CR><NL>), when reading files that are ":source"ed and for vimrc files, automatic <EOL> detection may be done:

- When **'fileformats'** is empty, there is no automatic detection. Dos format will be used.
- When **'fileformats'** is set to one or more names, automatic detection is done. This is based on the first <NL> in the file: If there is a <CR> in front of it, Dos format is used, otherwise Unix format is used.

Also see [file-formats](#) .

For backwards compatibility: When this option is set to an empty string or one format (no comma is included), **'textauto'** is reset, otherwise **'textauto'** is set.

**NOTE:** This option is set to the Vi default value when **'compatible'** is set and to the Vim default value when **'compatible'** is reset.

**'fileignorecase'** **'fic'** **'noignorecase'** **'nofic'**  
**'fileignorecase'** **'fic'** boolean (default on for systems where case in file names is normally ignored)  
global

When set case is ignored when using file names and directories.

See **'wildignorecase'** for only ignoring case when doing completion.

**'filetype'** **'ft'** **'filetype'** **'ft'**  
**'filetype'** **'ft'** string (default: "")  
local to buffer **local-noglobal**

When this option is set, the FileType autocommand event is triggered. All autocommands that match with the value of this option will be executed. Thus the value of **'filetype'** is used in place of the file name.

Otherwise this option does not always reflect the current file type. This option is normally set when the file type is detected. To enable this use the ":filetype on" command. **:filetype**

Setting this option to a different value is most useful in a modeline, for a file for which the file type is not automatically recognized.

Example, for in an IDL file:

```
/* vim: set filetype=idl : */
```

```
FileType filetypes
```

When a dot appears in the value then this separates two filetype names, it should therefore not be used for a filetype. Example:

```
/* vim: set filetype=c.doxygen : */
```

This will use the "c" filetype first, then the "doxygen" filetype.

This works both for filetype plugins and for syntax files. More than one dot may appear.  
 This option is not copied to another buffer, independent of the 's' or 'S' flag in '**coptions**'.  
 Only alphanumeric characters, '-' and '\_' can be used.

**'fillchars' 'fcs'** string (default "vert:|,fold:-,eob:~,lastline:@")  
 global or local to window **global-local**

Characters to fill the statuslines, vertical separators and special lines in the window.

It is a comma-separated list of items. Each item has a name, a colon and the value of that item: [E1511](#)

item name	default	Used for
stl	' '	statusline of the current window
stlnc	' '	statusline of the non-current windows
vert	' '	vertical separators <b>:vsplit</b>
fold	'-'	filling ' <b>foldtext</b> '
foldopen	'-'	mark the beginning of a fold
foldclose	'+'	show a closed fold
foldsep	' '	open fold middle character
diff	'-'	deleted lines of the ' <b>diff</b> ' option
eob	'~'	empty lines below the end of a buffer
lastline	'@'	<b>'display'</b> contains lastline/truncate

Any one that is omitted will fall back to the default.

Example:

```
:set fillchars=stl:\ ,stlnc:\ ,vert:|,fold:-,diff:-
```

For the "stl", "stlnc", "foldopen", "foldclose" and "foldsep" items single-byte and multibyte characters are supported. But double-width characters are not supported. [E1512](#)

The highlighting used for these items:

item name	highlight group
stl	StatusLine <b>hl-StatusLine</b>
stlnc	StatusLineNC <b>hl-StatusLineNC</b>
vert	VertSplit <b>hl-VertSplit</b>
fold	Folded <b>hl-Folded</b>
diff	DiffDelete <b>hl-DiffDelete</b>
eob	EndOfBuffer <b>hl-EndOfBuffer</b>
lastline	NonText <b>hl-NonText</b>

**'findfunc' 'ffu'** string (default empty) **'findfunc' 'ffu' E1514**  
 global or local to buffer **global-local**  
 {not available when compiled without the **+eval** feature}

Function that is called to obtain the filename(s) for the **:find** command. When this option is empty, the internal **file-searching** mechanism is used.

The value can be the name of a function, a `lambda` or a `Funcref` . See `option-value-function` for more information.

The function is called with two arguments. The first argument is a `String` and is the `:find` command argument. The second argument is a `Boolean` and is set to `v:true` when the function is called to get a List of command-line completion matches for the `:find` command. The function should return a List of strings.

The function is called only once per `:find` command invocation. The function can process all the directories specified in `'path'`.

If a match is found, the function should return a `List` containing one or more file names. If a match is not found, the function should return an empty List.

If any errors are encountered during the function invocation, an empty List is used as the return value.

It is not allowed to change text or jump to another window while executing the `'findfunc'` `textlock` .

This option cannot be set from a `modeline` or in the `sandbox` , for security reasons.

Examples:

```
" Use glob()
func FindFuncGlob(cmdarg, cmdcomplete)
 let pat = a:cmdcomplete ? '${a:cmdarg}*' : a:cmdarg
 return glob(pat, v:false, v:true)
endfunc
set findfunc=FindFuncGlob

" Use the 'git ls-files' output
func FindGitFiles(cmdarg, cmdcomplete)
 let fnames = systemlist('git ls-files')
 return fnames->filter('v:val =~? a:cmdarg')
endfunc
set findfunc=FindGitFiles
```

```
'fixendofline' 'fixeol' 'nofixendofline' 'nofixeol'
'fixendofline' 'fixeol' boolean (default on)
 local to buffer
```

When writing a file and this option is on, `<EOL>` at the end of file will be restored if missing. Turn this option off if you want to preserve the situation from the original file.

When the `'binary'` option is set the value of this option doesn't matter.

See the `'endofline'` option.

See `eol-and-eof` for example settings.

```
'fkmap' 'fk' 'fkmap' 'fk' 'nofkmap' 'nofk'
'fkmap' 'fk' boolean (default off)
```

global  
{only available when compiled with the `+rightleft`  
feature}

This option was for using Farsi, which has been removed. See [farsi.txt](#) .

`'foldclose'` `'fcl'` `'foldclose'` `'fcl'`  
`'foldclose'` `'fcl'` string (default "")  
global  
{not available when compiled without the `+folding`  
feature}

When set to "all", a fold is closed when the cursor isn't in it and its level is higher than `'foldlevel'`. Useful if you want folds to automatically close when moving out of them.

`'foldcolumn'` `'fdc'` `'foldcolumn'` `'fdc'`  
`'foldcolumn'` `'fdc'` number (default 0)  
local to window  
{not available when compiled without the `+folding`  
feature}

When non-zero, a column with the specified width is shown at the side of the window which indicates open and closed folds. The maximum value is 12.  
See [folding](#) .

`'foldenable'` `'fen'` `'foldenable'` `'fen'` `'nofoldenable'` `'nofen'`  
`'foldenable'` `'fen'` boolean (default on)  
local to window  
{not available when compiled without the `+folding`  
feature}

When off, all folds are open. This option can be used to quickly switch between showing all text unfolded and viewing the text with folds (including manually opened or closed folds). It can be toggled with the `zi` command. The `'foldcolumn'` will remain blank when `'foldenable'` is off.

This option is set by commands that create a new fold or close a fold. See [folding](#) .

`'foldexpr'` `'fde'` `'foldexpr'` `'fde'`  
`'foldexpr'` `'fde'` string (default: "0")  
local to window  
{not available when compiled without the `+folding`  
or `+eval` features}

The expression used for when `'foldmethod'` is "expr". It is evaluated for each line to obtain its fold level. The context is set to the script where `'foldexpr'` was set, script-local items can be accessed. See [fold-expr](#) for the usage.

The expression will be evaluated in the `sandbox` if set from a modeline, see [sandbox-option](#) .

This option can't be set from a `modeline` when the `'diff'` option is on or the `'modelineexpr'` option is off.

It is not allowed to change text or jump to another window while

evaluating **'foldexpr'** `textlock` .

**'foldignore'** **'fdi'** **'foldignore'** **'fdi'**  
string (default: "#")  
local to window  
{not available when compiled without the `+folding`  
feature}

Used only when **'foldmethod'** is "indent". Lines starting with characters in **'foldignore'** will get their fold level from surrounding lines. White space is skipped before checking for this character. The default "#" works well for C programs. See `fold-indent` .

**'foldlevel'** **'fdl'** **'foldlevel'** **'fdl'**  
number (default: 0)  
local to window  
{not available when compiled without the `+folding`  
feature}

Sets the fold level: Folds with a higher level will be closed. Setting this option to zero will close all folds. Higher numbers will close fewer folds. This option is set by commands like `zm` , `zM` and `zR` . See `fold-foldlevel` .

**'foldlevelstart'** **'fdls'** **'foldlevelstart'** **'fdls'**  
number (default: -1)  
global  
{not available when compiled without the `+folding`  
feature}

Sets **'foldlevel'** when starting to edit another buffer in a window. Useful to always start editing with all folds closed (value zero), some folds closed (one) or no folds closed (99). This is done before reading any modeline, thus a setting in a modeline overrules this option. Starting to edit a file for `diff-mode` also ignores this option and closes all folds. It is also done before `BufReadPre` autocommands, to allow an autocmd to overrule the **'foldlevel'** value for specific files. When the value is negative, it is not used.

**'foldmarker'** **'fmr'** **'foldmarker'** **'fmr'** E536  
string (default: "{{{,}}}")  
local to window  
{not available when compiled without the `+folding`  
feature}

The start and end marker used when **'foldmethod'** is "marker". There must be one comma, which separates the start and end marker. The marker is a literal string (a regular expression would be too slow). See `fold-marker` .

**'foldmethod'** **'fdm'** **'foldmethod'** **'fdm'**  
string (default: "manual")  
local to window  
{not available when compiled without the `+folding`  
feature}

The kind of folding used for the current window. Possible values:

fold-manual	manual	Folds are created manually.
fold-indent	indent	Lines with equal indent form a fold.
fold-expr	expr	' <b>foldexpr</b> ' gives the fold level of a line.
fold-marker	marker	Markers are used to specify folds.
fold-syntax	syntax	Syntax highlighting items specify folds.
fold-diff	diff	Fold text that is not changed.

'**foldminlines**'   '**fml**'

**'foldminlines'** '**fml**'   number (default: 1)  
 local to window  
 {not available when compiled without the **+folding**  
 feature}

Sets the number of screen lines above which a fold can be displayed closed. Also for manually closed folds. With the default value of one a fold can only be closed if it takes up two or more screen lines. Set to zero to be able to close folds of just one screen line.

**Note** that this only has an effect on what is displayed. After using "zc" to close a fold, which is displayed open because it's smaller than '**foldminlines**', a following "zc" may close a containing fold.

'**foldnestmax**'   '**fdn**'

**'foldnestmax'** '**fdn**'   number (default: 20)  
 local to window  
 {not available when compiled without the **+folding**  
 feature}

Sets the maximum nesting of folds for the "indent" and "syntax" methods. This avoids that too many folds will be created. Using more than 20 doesn't work, because the internal limit is 20.

'**foldopen**'   '**fdo**'

**'foldopen'** '**fdo**'   string (default: "block,hor,mark,percent,quickfix,  
 search,tag,undo")  
 global  
 {not available when compiled without the **+folding**  
 feature}

Specifies for which type of commands folds will be opened, if the command moves the cursor into a closed fold. It is a comma-separated list of items.

**NOTE:** When the command is part of a mapping this option is not used. Add the **zv** command to the mapping to get the same effect.

(rationale: the mapping may want to control opening folds itself)

item	commands
all	any
block	"(", "{", "[[", "[{", etc.
hor	horizontal movements: "l", "w", "fx", etc.
insert	any command in Insert mode
jump	far jumps: "G", "gg", etc.
mark	jumping to a mark: "'m", <b>CTRL-O</b> , etc.
percent	"%"
quickfix	":cn", ":crew", ":make", etc.
search	search for a pattern: "/", "n", "x", "gd", etc. (not for a search pattern in a ":" command) Also for [s and ]s .

tag                    jumping to a tag: ":ta", **CTRL-T**, etc.  
undo                    undo or redo: "u" and **CTRL-R**

When a movement command is used for an operator (e.g., "dl" or "y%") this option is not used. This means the operator will include the whole closed fold.

**Note** that vertical movements are not here, because it would make it very difficult to move onto a closed fold.

In insert mode the folds containing the cursor will always be open when text is inserted.

To close folds you can re-apply **'foldlevel'** with the `zx` command or set the **'foldclose'** option to "all".

**'foldtext'** **'fdt'**                    **'foldtext'**    **'fdt'**  
string (default: "foldtext()")  
local to window  
{not available when compiled without the `+folding`  
feature}

An expression which is used to specify the text displayed for a closed fold. The context is set to the script where **'foldexpr'** was set, script-local items can be accessed. See `fold-foldtext` for the usage.

The expression will be evaluated in the `sandbox` if set from a modeline, see `sandbox-option` .

This option cannot be set in a modeline when **'modelineexpr'** is off.

It is not allowed to change text or jump to another window while evaluating **'foldtext'** `textlock` .

**'formatexpr'** **'fex'**                    **'formatexpr'**    **'fex'**  
string (default "")  
local to buffer  
{not available when compiled without the `+eval`  
feature}

Expression which is evaluated to format a range of lines for the `gq` operator or automatic formatting (see **'formatoptions'**). When this option is empty **'formatprg'** is used.

The `v:lnum` variable holds the first line to be formatted.

The `v:count` variable holds the number of lines to be formatted.

The `v:char` variable holds the character that is going to be inserted if the expression is being evaluated due to automatic formatting. This can be empty. Don't insert it yet!

Example:

```
:set formatexpr=mylang#Format()
```

This will invoke the `mylang#Format()` function in the `autoload/mylang.vim` file in **'runtimepath'**. `autoload`

The advantage of using a function call without arguments is that it is faster, see `expr-option-function` .

The expression is also evaluated when **'textwidth'** is set and adding

text beyond that limit. This happens under the same conditions as when internal formatting is used. Make sure the cursor is kept in the same spot relative to the text then! The `mode()` function will return "i" or "R" in this situation.

When the expression evaluates to non-zero Vim will fall back to using the internal format mechanism.

If the expression starts with `s:` or `<SID>`, then it is replaced with the script ID (`local-function`). Example:

```
set formatexpr=s:MyFormatExpr()
set formatexpr=<SID>SomeFormatExpr()
```

Otherwise, the expression is evaluated in the context of the script where the option was set, thus script-local items are available.

The expression will be evaluated in the `sandbox` when set from a modeline, see `sandbox-option`. That stops the option from working, since changing the buffer text is not allowed.

This option cannot be set in a modeline when `'modelineexpr'` is off.

**NOTE:** This option is set to "" when `'compatible'` is set.

`'formatlistpat' 'flp'` string (default: `^\s*\d\+([\]:.])\t ]\s*`)  
local to buffer

A pattern that is used to recognize a list header. This is used for the "n" flag in `'formatoptions'`.

The pattern must match exactly the text that will be the indent for the line below it. You can use `/\ze` to mark the end of the match while still checking more characters. There must be a character following the pattern, when it matches the whole line it is handled like there is no match.

The default recognizes a number, followed by an optional punctuation character and white space.

`'formatoptions' 'fo'` string (Vim default: `"tcq"`, Vi default: `"vt"`)  
local to buffer

This is a sequence of letters which describes how automatic formatting is to be done.

See `fo-table` for possible values and `gq` for how to format text. When the `'paste'` option is on, no formatting is done (like `'formatoptions'` is empty). Commas can be inserted for readability. To avoid problems with flags that are added in the future, use the `"+="` and `"-="` feature of `":set"` `add-option-flags`.

**NOTE:** This option is set to the Vi default value when `'compatible'` is set and to the Vim default value when `'compatible'` is reset.

`'formatprg' 'fp'` string (default `""`)  
global or local to buffer `global-local`

The name of an external program that will be used to format the lines selected with the `gq` operator. The program must take the input on stdin and produce the output on stdout. The Unix program `"fmt"` is such a program.

If the **'formatexpr'** option is not empty it will be used instead. Otherwise, if **'formatprg'** option is an empty string, the internal format function will be used [C-indenting](#) . Environment variables are expanded [:set\\_env](#) . See [option-backslash](#) about including spaces and backslashes. This option cannot be set from a [modeline](#) or in the [sandbox](#) , for security reasons.

**'fsync'** **'fs'** ['fsync'](#) ['fs'](#) ['nofsync'](#) ['nofs'](#)  
 boolean (default on)  
 global

When on, the library function fsync() will be called after writing a file. This will flush a file to disk, ensuring that it is safely written even on filesystems which do metadata-only journaling. This will force the harddrive to spin up on Linux systems running in laptop mode, so it may be undesirable in some situations. Be warned that turning this off increases the chances of data loss after a crash. On systems without an fsync() implementation, this variable is always off.

Also see **'swapsync'** for controlling fsync() on swap files.

**'fsync'** also applies to [writefile\(\)](#) (unless a flag is used to overrule it) and when writing undo files (see [undo-persistence](#) ). This option cannot be set from a [modeline](#) or in the [sandbox](#) , for security reasons.

**'gdefault'** **'gd'** ['gdefault'](#) ['gd'](#) ['nogdefault'](#) ['nogd'](#)  
 boolean (default off)  
 global

When on, the `":substitute"` flag 'g' is default on. This means that all matches in a line are substituted instead of one. When a 'g' flag is given to a `":substitute"` command, this will toggle the substitution of all or one match. See [complex-change](#) .

command	<a href="#">'gdefault'</a> on	<a href="#">'gdefault'</a> off
<code>:s///</code>	subst. all	subst. one
<code>:s///g</code>	subst. one	subst. all
<code>:s///gg</code>	subst. all	subst. one

**NOTE:** This option is reset when **'compatible'** is set. Setting this option may break plugins that rely on the default behavior of the 'g' flag. This will also make the 'g' flag have the opposite effect of that documented in [:s\\_g](#) . This option is not used in [Vim9](#) script.

**'grepformat'** **'gfm'** ['grepformat'](#) ['gfm'](#)  
 string (default `"%f:%l:%m,%f:%l%m,%f %l%m"`)  
 global

Format to recognize for the `":grep"` command output. This is a scanf-like string that uses the same format as the **'errorformat'** option: see [errorformat](#) .

**'grepprg'** **'gp'** ['grepprg'](#) ['gp'](#)  
 string (default `"grep -n "`,  
 Unix: `"grep -n $* /dev/null"`,

Win32: "findstr /n" or "grep -n",  
VMS: "SEARCH/NUMBERS ")

global or local to buffer `global-local`

Program to use for the `:grep` command. This option may contain '%' and '#' characters, which are expanded like when used in a command-line. The placeholder "\$\*" is allowed to specify where the arguments will be included. Environment variables are expanded `:set_env`. See `option-backslash` about including spaces and backslashes.

When your "grep" accepts the "-H" argument, use this to make ":grep" also work well with a single file:

```
:set grepprg=grep\ -nH
```

Special value: When `'grepprg'` is set to "internal" the `:grep` command works like `:vimgrep`, `:lgrep` like `:lvimgrep`, `:grepadd` like `:vimgrepadd` and `:lgrepadd` like `:lvimgrepadd`.

See also the section `:make_makeprg`, since most of the comments there apply equally to `'grepprg'`.

For Win32, the default is "findstr /n" if "findstr.exe" can be found, otherwise it's "grep -n".

This option cannot be set from a `modeline` or in the `sandbox`, for security reasons.

```
'guicursor' 'gcr' 'guicursor' 'gcr' E545 E546 E548 E549
string (default "n-v-c:block-Cursor/lCursor,
 ve:ver35-Cursor,
 o:hor50-Cursor,
 i-ci:ver25-Cursor/lCursor,
 r-cr:hor20-Cursor/lCursor,
 sm:block-Cursor
 -blinkwait175-blinkoff150-blinkon175",
 for Win32 console:
 "n-v-c:block,o:hor50,i-ci:hor15,
 r-cr:hor30,sm:block")

global
{only available when compiled with GUI enabled, and
for Win32 console}
```

This option tells Vim what the cursor should look like in different modes. It fully works in the GUI. In a Win32 console, only the height of the cursor can be changed. This can be done by specifying a block cursor, or a percentage for a vertical or horizontal cursor. For a console the `'t_SI'`, `'t_SR'`, and `'t_EI'` escape sequences are used.

The option is a comma-separated list of parts. Each part consist of a mode-list and an argument-list:

```
mode-list:argument-list,mode-list:argument-list,..
```

The mode-list is a dash separated list of these modes:

```
n Normal mode
v Visual mode
ve Visual mode with 'selection' "exclusive" (same as 'v',
 if not specified)
o Operator-pending mode
i Insert mode
r Replace mode
c Command-line Normal (append) mode
```

```

ci Command-line Insert mode
cr Command-line Replace mode
sm showmatch in Insert mode
a all modes

```

The argument-list is a dash separated list of these arguments:

```

hor{N} horizontal bar, {N} percent of the character height
ver{N} vertical bar, {N} percent of the character width
block block cursor, fills the whole character
 [only one of the above three should be present]
blinkwait{N}
blinkon{N}
blinkoff{N}

```

cursor-blinking

blink times for cursor: blinkwait is the delay before the cursor starts blinking, blinkon is the time that the cursor is shown and blinkoff is the time that the cursor is not shown. The times are in msec. When one of the numbers is zero, there is no blinking. The default is: "blinkwait700-blinkon400-blinkoff250". These numbers are used for a missing entry. This means that blinking is enabled by default. To switch blinking off you can use "blinkon0". The cursor only blinks when Vim is waiting for input, not while executing a command.

To make the cursor blink in an xterm, see [xterm-blink](#) .

{group-name}

a highlight group name, that sets the color and font for the cursor

{group-name}/{group-name}

Two highlight group names, the first is used when no language mappings are used, the other when they are. [language-mapping](#)

Examples of parts:

```

n-c-v:block-nCursor in Normal, Command-line and Visual mode, use a
 block cursor with colors from the "nCursor"
 highlight group

```

```

i-ci:ver30-iCursor-blinkwait300-blinkon200-blinkoff150

```

In Insert and Command-line Insert mode, use a 30% vertical bar cursor with colors from the "iCursor" highlight group. Blink a bit faster.

The 'a' mode is different. It will set the given argument-list for all modes. It does not reset anything to defaults. This can be used to do a common setting for all modes. For example, to switch off blinking: "a:blinkon0"

Examples of cursor highlighting:

```

:highlight Cursor gui=reverse guifg=NONE guibg=NONE
:highlight Cursor gui=NONE guifg=bg guibg=fg

```

```

'guifont' 'gfn'
E235 E596

```

**'guifont' 'gfn'** string (default "")  
global  
{only available when compiled with GUI enabled}

This is a list of fonts which will be used for the GUI version of Vim. In its simplest form the value is just one font name. See [gui-font](#) for the details.

**'guifontset' 'gfs'** string (default "")  
global  
{only available when compiled with GUI enabled and with the [+xfontset](#) feature}  
{not available in the GTK+ GUI}

When not empty, specifies two (or more) fonts to be used. The first one for normal English, the second one for your special language. See [xfontset](#) .

**'guifontwide' 'gfw'** string (default "")  
global  
{only available when compiled with GUI enabled}

When not empty, specifies a comma-separated list of fonts to be used for double-width characters. The first font that can be loaded is used. See [gui-fontwide](#) .

**'guiheadroom' 'ghr'** number (default 50)  
global  
{only for GTK and X11 GUI}

The number of pixels subtracted from the screen height when fitting the GUI window on the screen. Set this before the GUI is started, e.g., in your [gvimrc](#) file. When zero, the whole screen height will be used by the window. When positive, the specified number of pixel lines will be left for window decorations and other items on the screen. Set it to a negative value to allow windows taller than the screen.

**'guiligatures' 'gli'** string (default "")  
global  
{only for GTK and Win32 GUI}

List of ASCII characters that, when combined together, can create more complex shapes. Each character must be a printable ASCII character with a value in the 32-127 range.

Example:

```
:set guiligatures=!\"#$%&()*+-./:<=>?@[]^_{|~
```

Changing this option updates screen output immediately. Set it to an empty string to disable ligatures.

**'guioptions' 'go'** string (default "egmrLt" (MS-Windows,  
"t" is removed in [defaults.vim](#) ),  
"aegimrLt" (GTK and Motif),

```

)
global
{only available when compiled with GUI enabled}

```

This option only has an effect in the GUI version of Vim. It is a sequence of letters which describes what components and options of the GUI should be used.

To avoid problems with flags that are added in the future, use the "+" and "-" feature of ":set" [add-option-flags](#) .

Valid characters are as follows:

- '!' External commands are executed in a terminal window. Without this flag the MS-Windows GUI will open a console window to execute the command. The Unix GUI will simulate a dumb terminal to list the command output. The terminal window will be positioned at the bottom, and grow upwards as needed. 'go-!'
- 'a' Autoselect: If present, then whenever VISUAL mode is started, or the Visual area extended, Vim tries to become the owner of the windowing system's global selection. This means that the Visually highlighted text is available for pasting into other applications as well as into Vim itself. When the Visual mode ends, possibly due to an operation on the text, or when an application wants to paste the selection, the highlighted text is automatically yanked into the "\*" selection register. Thus the selection is still available for pasting into other applications after the VISUAL mode has ended. If not present, then Vim won't become the owner of the windowing system's global selection unless explicitly told to by a yank or delete operation for the "\*" register. The same applies to the modeless selection. 'go-a'
- 'P' Like autoselect but using the "+" register instead of the "\*" register. 'go-P'
- 'A' Autoselect for the modeless selection. Like 'a', but only applies to the modeless selection. 'go-A'

'guioptions'	autoselect Visual	autoselect modeless
""	-	-
"a"	yes	yes
"A"	-	yes
"aA"	yes	yes

When using a terminal see the **'clipboard'** option.

- 'c' Use console dialogs instead of popup dialogs for simple choices. 'go-c'
- 'd' Use dark theme variant if available. Currently only works for GTK+ GUI. 'go-d'

'go-e'

- 'e' Add tab pages when indicated with **'showtabline'**.  
**'guitablabel'** can be used to change the text in the labels.  
When 'e' is missing a non-GUI tab pages line may be used.  
The GUI tabs are only supported on some systems, currently  
GTK, Motif, Mac OS/X, Haiku, and MS-Windows. 'go-f'
- 'f' Foreground: Don't use fork() to detach the GUI from the shell  
where it was started. Use this for programs that wait for the  
editor to finish (e.g., an e-mail program). Alternatively you  
can use "gvim -f" or ":gui -f" to start the GUI in the  
foreground. [gui-fork](#)  
**Note:** Set this option in the vimrc file. The forking may have  
happened already when the [gvimrc](#) file is read. 'go-i'
- 'i' Use a Vim icon. For GTK with KDE it is used in the left-upper  
corner of the window. It's black&white on non-GTK, because of  
limitations of X11. For a color icon, see [X11-icon](#) .  
'go-m'
- 'm' Menu bar is present. 'go-M'
- 'M' The system menu "\$VIMRUNTIME/menu.vim" is not sourced. **Note**  
that this flag must be added in the .vimrc file, before  
switching on syntax or filetype recognition (when the [gvimrc](#)  
file is sourced the system menu has already been loaded; the  
`:syntax on` and `:filetype on` commands load the menu too).  
'go-g'
- 'g' Grey menu items: Make menu items that are not active grey. If  
'g' is not included inactive menu items are not shown at all.  
'go-t'
- 't' Include tearoff menu items. Currently only works for Win32,  
GTK+, and Motif 1.2 GUI. 'go-T'
- 'T' Include Toolbar. Currently only in Win32, GTK+, Motif and  
Photon GUIs. 'go-r'
- 'r' Right-hand scrollbar is always present. 'go-R'
- 'R' Right-hand scrollbar is present when there is a vertically  
split window. 'go-l'
- 'l' Left-hand scrollbar is always present. 'go-L'
- 'L' Left-hand scrollbar is present when there is a vertically  
split window. 'go-b'
- 'b' Bottom (horizontal) scrollbar is present. Its size depends on  
the longest visible line, or on the cursor line if the 'h'  
flag is included. [gui-horiz-scroll](#) 'go-h'
- 'h' Limit horizontal scrollbar size to the length of the cursor  
line. Reduces computations. [gui-horiz-scroll](#)

And yes, you may even have scrollbars on the left AND the right if  
you really want to :-). See [gui-scrollbars](#) for more information.

- 'go-v'
 'v' Use a vertical button layout for dialogs. When not included, a horizontal layout is preferred, but when it doesn't fit a vertical layout is used anyway. Not supported in GTK 3.
- 'go-p'
 'p' Use Pointer callbacks for X11 GUI. This is required for some window managers. If the cursor is not blinking or hollow at the right moment, try adding this flag. This must be done before starting the GUI. Set it in your `gvimrc`. Adding or removing it after the GUI has started has no effect.
- 'go-F'
 'F' Add a footer. Only for Motif. See `gui-footer`.
- 'go-k'
 'k' Keep the GUI window size when adding/removing a scrollbar, or toolbar, tabline, etc. Instead, the behavior is similar to when the window is maximized and will adjust `'lines'` and `'columns'` to fit to the window. Without the 'k' flag Vim will try to keep `'lines'` and `'columns'` the same when adding and removing GUI components.

'guipty' 'noguipty'

**'guipty'**                   boolean (default on)  
                           global  
                           {only available when compiled with GUI enabled}

Only in the GUI: If on, an attempt is made to open a pseudo-tty for I/O to/from shell commands. See `gui-pty`.

'guitablabel' 'gtl'

**'guitablabel' 'gtl'**       string (default empty)  
                           global  
                           {only available when compiled with GUI enabled}

When non-empty describes the text to use in a label of the GUI tab pages line. When empty and when the result is empty Vim will use a default label. See `setting-guitablabel` for more info.

The format of this option is like that of `'statusline'`. `'guitabtooltip'` is used for the tooltip, see below. The expression will be evaluated in the `sandbox` when set from a modeline, see `sandbox-option`. This option cannot be set in a modeline when `'modelineexpr'` is off.

Only used when the GUI tab pages line is displayed. 'e' must be present in `'guioptions'`. For the non-GUI tab pages line `'tabline'` is used.

'guitabtooltip' 'gtt'

**'guitabtooltip' 'gtt'**     string (default empty)  
                           global  
                           {only available when compiled with GUI enabled}

When non-empty describes the text to use in a tooltip for the GUI tab pages line. When empty Vim will use a default tooltip. This option is otherwise just like `'guitablabel'` above. You can include a line break. Simplest method is to use `:let :`

```
:let &guitabtooltip = "line one\nline two"
```

**'helpfile' 'hf'** 'helpfile' 'hf'  
string (default (MS-Windows) "\$VIMRUNTIME/doc/help.txt"  
(others) "\$VIMRUNTIME/doc/help.txt")

global

Name of the main help file. All distributed help files should be placed together in one directory. Additionally, all "doc" directories in '**runtimepath**' will be used.

Environment variables are expanded `:set_env` . For example: "\$VIMRUNTIME/doc/help.txt". If \$VIMRUNTIME is not set, \$VIM is also tried. Also see `$VIMRUNTIME` and `option-backslash` about including spaces and backslashes.

This option cannot be set from a `modeline` or in the `sandbox` , for security reasons.

**'helpheight' 'hh'** 'helpheight' 'hh'  
number (default 20)  
global

Minimal initial height of the help window when it is opened with the ":help" command. The initial height of the help window is half of the current window, or (when the '**ea**' option is on) the same as other windows. When the height is less than '**helpheight**', the height is set to '**helpheight**'. Set to zero to disable.

**'helplang' 'hlg'** 'helplang' 'hlg'  
string (default: messages language or empty)  
global  
{only available when compiled with the `+multi_lang`  
feature}

Comma-separated list of languages. Vim will use the first language for which the desired help can be found. The English help will always be used as a last resort. You can add "en" to prefer English over another language, but that will only find tags that exist in that language and not in the English help.

Example:

```
:set helplang=de,it
```

This will first search German, then Italian and finally English help files.

When using `CTRL-]` and ":help!" in a non-English help file Vim will try to find the tag in the current language before using this option. See `help-translated` .

**'hidden' 'hid'** 'hidden' 'hid' 'nohidden' 'nohid'  
boolean (default off)  
global

When off a buffer is unloaded when it is `abandon` ed. When on a buffer becomes hidden when it is `abandon` ed. If the buffer is still displayed in another window, it does not become hidden, of course.

The commands that move through the buffer list sometimes make a buffer hidden even if the '**hidden**' option is off when these three are true:

- the buffer is modified

- **'autowrite'** is off or writing is not possible
  - the **'!'** flag was used
- Also see [windows.txt](#) .

To only make one buffer hidden use the **'bufhidden'** option.  
 This option is set for one command with `":hide {command}" :hide` .  
 WARNING: It's easy to forget that you have changes in hidden buffers.  
 Think twice when using `":q!"` or `":qa!"`.

**'highlight' 'hl'** string (default (as a single string):

```

 "8:SpecialKey,~:EndOfBuffer,@:NonText,
 d:Directory,e:ErrorMsg,i:IncSearch,
 l:Search,m:MoreMsg,M:ModeMsg,n:LineNr,
 a:LineNrAbove,b:LineNrBelow,
 N:CursorLineNr,r:Question,s:StatusLine,
 S:StatusLineNC,c:VertSplit,t:Title,
 v:Visual,V:VisualNOS,w:WarningMsg,
 W:WildMenu,f:Folded,F:FoldColumn,
 A:DiffAdd,C:DiffChange,D:DiffDelete,
 T:DiffText,>:SignColumn,-:Conceal,
 B:SpellBad,P:SpellCap,R:SpellRare,
 L:SpellLocal,+:Pmenu,=:PmenuSel,
 k:PmenuMatch,<:PmenuMatchSel,
 [:PmenuKind,]:PmenuKindSel,
 {:PmenuExtra,}:PmenuExtraSel,
 x:PmenuSbar,X:PmenuThumb,*:TabLine,
 #:TabLineSel,_:TabLineFill,!:CursorColumn,
 .:CursorLine,o:ColorColumn,q:QuickFixLine,
 z:StatusLineTerm,Z:StatusLineTermNC,
 g:MsgArea,h:ComplMatchIns")

```

global

This option can be used to set highlighting mode for various occasions. It is a comma-separated list of character pairs. The first character in a pair gives the occasion, the second the mode to use for that occasion. The occasions are:

<b>hl-SpecialKey</b>	8	Meta and special keys listed with <code>":map"</code>
<b>hl-EndOfBuffer</b>	~	lines after the last line in the buffer
<b>hl-NonText</b>	@	'@' at the end of the window and characters from <b>'showbreak'</b>
<b>hl-Directory</b>	d	directories in <b>CTRL-D</b> listing and other special things in listings
<b>hl-ErrorMsg</b>	e	error messages
	h	(obsolete, ignored)
<b>hl-IncSearch</b>	i	<b>'incsearch'</b> highlighting
<b>hl-CurSearch</b>	y	current instance of last search pattern
<b>hl-Search</b>	l	last search pattern highlighting (see <b>'hlsearch'</b> )
<b>hl-MoreMsg</b>	m	<b>more-prompt</b>
<b>hl-ModeMsg</b>	M	Mode (e.g., <code>-- INSERT --</code> )
<b>hl-MsgArea</b>	g	<b>Command-line</b> and message area
<b>hl-ComplMatchIns</b>	h	matched text of currently inserted completion
<b>hl-LineNr</b>	n	line number for <code>":number"</code> and <code>":#"</code> commands, and when <b>'number'</b> or <b>'relativenumber'</b> option is set.
<b>hl-LineNrAbove</b>	a	line number above the cursor for when the

'**relativenumber**' option is set.

hl-LineNrBelow b line number below the cursor for when the '**relativenumber**' option is set.

hl-CursorLineNr N like n for when '**cursorline**' or '**relativenumber**' is set.

hl-Question r **hit-enter** prompt and yes/no questions

hl-StatusLine s status line of current window **status-line**

hl-StatusLineNC S status lines of not-current windows

hl-Title t Titles for output from ":set all", ":autocmd" etc.

hl-VertSplit c column used to separate vertically split windows

hl-Visual v Visual mode

hl-VisualNOS V Visual mode when Vim does is "Not Owning the Selection" Only X11 Gui's **gui-x11** and **xterm-clipboard** .

hl-WarningMsg w warning messages

hl-WildMenu W wildcard matches displayed for '**wildmenu**'

hl-Folded f line used for closed folds

hl-FoldColumn F '**foldcolumn**'

hl-DiffAdd A added line in diff mode

hl-DiffChange C changed line in diff mode

hl-DiffDelete D deleted line in diff mode

hl-DiffText T inserted text in diff mode

hl-SignColumn > column used for **signs**

hl-Conceal - the placeholders used for concealed characters (see '**conceallevel**')

hl-SpellBad B misspelled word **spell**

hl-SpellCap P word that should start with capital **spell**

hl-SpellRare R rare word **spell**

hl-SpellLocal L word from other region **spell**

hl-Pmenu + popup menu normal line

hl-PmenuSel = popup menu selected line

hl-PmenuKind [ popup menu "kind" normal line

hl-PmenuKindSel ] popup menu "kind" selected line

hl-PmenuExtra { popup menu "extra" normal line

hl-PmenuExtraSel } popup menu "extra" selected line

hl-PmenuSbar x popup menu scrollbar

hl-PmenuThumb X popup menu scrollbar thumb

hl-PmenuMatch k popup menu matched text

hl-PmenuMatchSel < popup menu matched text in selected line

The display modes are:

r	reverse	(termcap entry "mr" and "me")
i	italic	(termcap entry "ZH" and "ZR")
b	bold	(termcap entry "md" and "me")
s	standout	(termcap entry "so" and "se")
u	underline	(termcap entry "us" and "ue")
c	undercurl	(termcap entry "Us" and "Ce")
2	double underline	(termcap entry "Ds" and "Ce")
d	dotted underline	(termcap entry "ds" and "Ce")
=	dashed underline	(termcap entry "Ds" and "Ce")
t	strikethrough	(termcap entry "Ts" and "Te")
n	no highlighting	
-	no highlighting	
:	use a highlight group	

The default is used for occasions that are not included. If you want to change what the display modes do, see [dos-colors](#) for an example. When using the ':' display mode, this must be followed by the name of a highlight group. A highlight group can be used to define any type of highlighting, including using color. See [:highlight](#) on how to define one. The default uses a different group for each occasion. See [highlight-default](#) for the default highlight groups.

**'history' 'hi'** 'history' 'hi'  
 number (Vim default: 200, Vi default: 0)  
 global  
 A history of ":" commands, and a history of previous search patterns is remembered. This option decides how many entries may be stored in each of these histories (see [cmdline-editing](#) and ['messagesopt'](#) for the number of messages to remember). The maximum value is 10000.  
**NOTE:** This option is set to the Vi default value when ['compatible'](#) is set and to the Vim default value when ['compatible'](#) is reset.

**'hkmap' 'hk'** 'hkmap' 'hk' 'nohkmap' 'nohk'  
 boolean (default off)  
 global  
 {only available when compiled with the [+rightleft](#) feature}  
 When on, the keyboard is mapped for the Hebrew character set. Normally you would set ['allowrevins'](#) and use CTRL-\_ in insert mode to toggle this option. See [rileft.txt](#) .  
**NOTE:** This option is reset when ['compatible'](#) is set.

**'hkmappp' 'hkp'** 'hkmappp' 'hkp' 'nohkmappp' 'nohkp'  
 boolean (default off)  
 global  
 {only available when compiled with the [+rightleft](#) feature}  
 When on, phonetic keyboard mapping is used. ['hkmap'](#) must also be on. This is useful if you have a non-Hebrew keyboard. See [rileft.txt](#) .  
**NOTE:** This option is reset when ['compatible'](#) is set.

**'hlsearch' 'hls'** 'hlsearch' 'hls' 'nohlsearch' 'nohls'  
 boolean (default off)  
 global  
 {not available when compiled without the [+extra\\_search](#) feature}  
 When there is a previous search pattern, highlight all its matches. The type of highlighting used can be set with the 'l' occasion in the ['highlight'](#) option. This uses the "Search" highlight group by default. **Note** that only the matching text is highlighted, any offsets are not applied. If the "CurSearch" highlight group is set then the current match is highlighted with that. See also: ['incsearch'](#) and [:match](#) .  
 When you get bored looking at the highlighted matches, you can turn it off with [:nohlsearch](#) . This does not change the option value, as

soon as you use a search command, the highlighting comes back. **'redrawtime'** specifies the maximum time spent on finding matches. When the search pattern can match an end-of-line, Vim will try to highlight all of the matched text. However, this depends on where the search starts. This will be the first line in the window or the first line below a closed fold. A match in a previous line which is not drawn may not continue in a newly drawn line. You can specify whether the highlight status is restored on startup with the 'h' flag in **'viminfo'** [viminfo-h](#) .  
**NOTE:** This option is reset when **'compatible'** is set.

**'icon'** **'icon'** **'noicon'**  
 boolean (default off, on when title can be restored)  
 global

When on, the icon text of the window will be set to the value of **'iconstring'** (if it is not empty), or to the name of the file currently being edited. Only the last part of the name is used. Overridden by the **'iconstring'** option. Only works if the terminal supports setting window icons (currently only X11 GUI and terminals with a non-empty **'t\_IS'** option - these are Unix xterm and iris-ansi by default, where **'t\_IS'** is taken from the builtin termcap). When Vim was compiled with HAVE\_X11 defined, the original icon will be restored if possible [X11](#) . See [X11-icon](#) for changing the icon on X11. For MS-Windows the icon can be changed, see [windows-icon](#) .

**'iconstring'** **'iconstring'**  
 string (default "")  
 global

When this option is not empty, it will be used for the icon text of the window. This happens only when the **'icon'** option is on. Only works if the terminal supports setting window icon text (currently only X11 GUI and terminals with a non-empty **'t\_IS'** option). Does not work for MS-Windows. When Vim was compiled with HAVE\_X11 defined, the original icon will be restored if possible [X11](#) . When this option contains printf-style '%' items, they will be expanded according to the rules used for **'statusline'**. See **'titlestring'** for example settings. This option cannot be set in a modeline when **'modelineexpr'** is off. {not available when compiled without the |+statusline| feature}

**'ignorecase'** **'ic'** **'ignorecase'** **'ic'** **'noignorecase'** **'noic'**  
 boolean (default off)  
 global

Ignore case in search patterns, [cmdline-completion](#) , when searching in the tags file, and non- Vim9 [expr-==](#) . Also see **'smartcase'** and **'tagcase'**. Can be overruled by using "\c" or "\C" in the pattern, see [/ignorecase](#) .

**'imactivatefunc'** **'imaf'** **'imactivatefunc'** **'imaf'**  
 string (default "")

global

This option specifies a function that will be called to activate or deactivate the Input Method. The value can be the name of a function, a `lambda` or a `Funcref`. See [option-value-function](#) for more information.

It is not used in the MS-Windows GUI version.

The expression will be evaluated in the `sandbox` when set from a modeline, see [sandbox-option](#).

Example:

```
function ImActivateFunc(active)
 if a:active
 ... do something
 else
 ... do something
 endif
 " return value is not used
endfunction
set imactivatefunc=ImActivateFunc
```

```
'imactivatekey' 'imak' string (default "")
 'imactivatekey' 'imak'
 global
 {only available when compiled with +xim and
 +GUI_GTK }
 E599
```

Specifies the key that your Input Method in X-Windows uses for activation. When this is specified correctly, vim can fully control IM with `'imcmdline'`, `'iminsert'` and `'imsearch'`.

You can't use this option to change the activation key, the option tells Vim what the key is.

Format:

```
[MODIFIER_FLAG-]KEY_STRING
```

These characters can be used for MODIFIER\_FLAG (case is ignored):

S	Shift key
L	Lock key
C	Control key
1	Mod1 key
2	Mod2 key
3	Mod3 key
4	Mod4 key
5	Mod5 key

Combinations are allowed, for example "S-C-space" or "SC-space" are both shift+ctrl+space.

See `<X11/keysymdef.h>` and `XStringToKeysym` for `KEY_STRING`.

Example:

```
:set imactivatekey=S-space
```

"S-space" means shift+space. This is the activation key for `kinput2` + `canna` (Japanese), and `ami` (Korean).

```
'imcmdline' 'imc'
 'imcmdline' 'imc' 'noimcmdline' 'noimc'
 boolean (default off)
 global
```

When set the Input Method is always on when starting to edit a command line, unless entering a search pattern (see **'imsearch'** for that). Setting this option is useful when your input method allows entering English characters directly, e.g., when it's used to type accented characters with dead keys.

**'imdisable'** **'imd'** **'imdisable'** **'imd'** **'noimdisable'** **'noimd'**  
boolean (default off, on for some systems (SGI))  
global

When set the Input Method is never used. This is useful to disable the IM when it doesn't work properly.

Currently this option is on by default for SGI/IRIX machines. This may change in later releases.

**'iminsert'** **'imi'** **'iminsert'** **'imi'**  
number (default 0)  
local to buffer

Specifies whether `:lmap` or an Input Method (IM) is to be used in Insert mode. Valid values:

0 :lmap is off and IM is off  
1 :lmap is ON and IM is off  
2 :lmap is off and IM is ON

To always reset the option to zero when leaving Insert mode with `<Esc>` this can be used:

```
:inoremap <ESC> <ESC>:set iminsert=0<CR>
```

This makes `:lmap` and IM turn off automatically when leaving Insert mode.

**Note** that this option changes when using **CTRL-^** in Insert mode `i_CTRL-^`.

The value is set to 1 when setting **'keymap'** to a valid keymap name.

It is also used for the argument of commands like "r" and "f".

The value 0 may not work correctly with Motif with some XIM methods. Use **'imdisable'** to disable XIM then.

You can set **'imactivatefunc'** and **'imstatusfunc'** to handle IME/XIM via external command if Vim is not compiled with the `+xim`, `+multi_byte_ime` or `global-ime`.

**'imsearch'** **'ims'** **'imsearch'** **'ims'**  
number (default -1)  
local to buffer

Specifies whether `:lmap` or an Input Method (IM) is to be used when entering a search pattern. Valid values:

-1 the value of **'iminsert'** is used, makes it look like **'iminsert'** is also used when typing a search pattern  
0 :lmap is off and IM is off  
1 :lmap is ON and IM is off  
2 :lmap is off and IM is ON

**Note** that this option changes when using **CTRL-^** in Command-line mode `c_CTRL-^`.

The value is set to 1 when it is not -1 and setting the **'keymap'** option to a valid keymap name.

The value 0 may not work correctly with Motif with some XIM methods. Use **'imdisable'** to disable XIM then.

**'imstatusfunc'** **'imsf'** string (default "")  
global

This option specifies a function that is called to obtain the status of Input Method. It must return a positive number when IME is active. The value can be the name of a function, a [lambda](#) or a [Funcref](#). See [option-value-function](#) for more information. It is not used in the MS-Windows GUI version.

Example:

```
function ImStatusFunc()
 let is_active = ...do something
 return is_active ? 1 : 0
endfunction
set imstatusfunc=ImStatusFunc
```

**NOTE:** This function is invoked very often. Keep it fast. The expression will be evaluated in the [sandbox](#) when set from a modeline, see [sandbox-option](#).

**'imstyle'** **'imst'** number (default 1)  
global  
{only available when compiled with [+xim](#) and [+GUI\\_GTK](#)}

This option specifies the input style of Input Method:  
0 use on-the-spot style  
1 over-the-spot style  
See: [xim-input-style](#)

For a long time on-the-spot style had been used in the GTK version of vim, however, it is known that it causes troubles when using mappings, [single-repeat](#), etc. Therefore over-the-spot style becomes the default now. This should work fine for most people, however if you have any problem with it, try using on-the-spot style. The expression will be evaluated in the [sandbox](#) when set from a modeline, see [sandbox-option](#).

**'include'** **'inc'** string (default "[^\s\\*#\s\\*include](#)")  
global or local to buffer [global-local](#)  
{not available when compiled without the [+find\\_in\\_path](#) feature}

Pattern to be used to find an include command. It is a search pattern, just like for the ["/](#) command (See [pattern](#)). The default value is for C programs. This option is used for the commands "[i", "]I", "[d", etc.

Normally the **'isfname'** option is used to recognize the file name that comes after the matched pattern. But if ["\zs"](#) appears in the pattern then the text matched from ["\zs"](#) to the end, or until ["\ze"](#) if it appears, is used as the file name. Use this to include characters that are not in **'isfname'**, such as a space. You can then use **'includeexpr'** to process the matched text.

See [option-backslash](#) about including spaces and backslashes.

**'includeexpr'** **'inex'** **'includeexpr'** **'inex'**  
string (default "")  
local to buffer  
{not available when compiled without the  
[+find\\_in\\_path](#) or [+eval](#) features}

Expression to be used to transform the string found with the **'include'** option to a file name. Mostly useful to change "." to "/" for Java:

```
:setlocal includeexpr=substitute(v:fname,'\\.', '/', 'g')
```

The "v:fname" variable will be set to the file name that was detected.

**Note** the double backslash: the `:set` command first halves them, then one remains it the value, where "\\." matches a dot literally. For simple character replacements `tr()` avoids the need for escaping:

```
:setlocal includeexpr=tr(v:fname, '.', '/')
```

Also used for the [gf](#) command if an unmodified file name can't be found. Allows doing "gf" on the name after an **'include'** statement. Also used for [<cfil>](#) .

If the expression starts with s: or [<SID>](#) , then it is replaced with the script ID ( [local-function](#) ). Example:

```
setlocal includeexpr=s:MyIncludeExpr()
setlocal includeexpr=<SID>SomeIncludeExpr()
```

Otherwise, the expression is evaluated in the context of the script where the option was set, thus script-local items are available.

It is more efficient if the value is just a function call without arguments, see [expr-option-function](#) .

The expression will be evaluated in the [sandbox](#) when set from a modeline, see [sandbox-option](#) .

This option cannot be set in a modeline when **'modelineexpr'** is off.

It is not allowed to change text or jump to another window while evaluating **'includeexpr'** [textlock](#) .

**'incsearch'** **'is'** **'incsearch'** **'is'** **'noincsearch'** **'nois'**  
boolean (default off, set in [defaults.vim](#) if the  
[+reltime](#) feature is supported)  
global  
{not available when compiled without the  
[+extra\\_search](#) features}

While typing a search command, show where the pattern, as it was typed so far, matches. The matched string is highlighted. If the pattern is invalid or not found, nothing is shown. The screen will be updated often, this is only useful on fast terminals.

Also applies to the pattern in commands:

```
:global
:lvimgrep
:lvimgrepadd
:smagic
:snomagic
:sort
```

```
:substitute
:vglobal
:vimgrep
:vimgrepadd
```

**Note** that the match will be shown, but the cursor will return to its original position when no match is found and when pressing `<Esc>`. You still need to finish the search command with `<Enter>` to move the cursor to the match.

You can use the **CTRL-G** and **CTRL-T** keys to move to the next and previous match. `c_CTRL-G` `c_CTRL-T`

When compiled with the `+reltime` feature Vim only searches for about half a second. With a complicated pattern and/or a lot of text the match may not be found. This is to avoid that Vim hangs while you are typing the pattern.

The highlighting can be set with the 'i' flag in **'highlight'**.

When **'hlsearch'** is on, all matched strings are highlighted too while typing a search command. See also: **'hlsearch'**.

If you don't want to turn **'hlsearch'** on, but want to highlight all matches while searching, you can turn on and off **'hlsearch'** with `autocmd`. Example:

```
augroup vimrc-incsearch-highlight
autocmd!
autocmd CmdlineEnter /,\? :set hlsearch
autocmd CmdlineLeave /,\? :set nohlsearch
augroup END
```

**CTRL-L** can be used to add one character from after the current match to the command line. If **'ignorecase'** and **'smartcase'** are set and the command line has no uppercase characters, the added character is converted to lowercase.

**CTRL-R CTRL-W** can be used to add the word at the end of the current match, excluding the characters that were already typed.

**NOTE:** This option is reset when **'compatible'** is set.

```
'indentexpr' 'inde' 'indentexpr' 'inde'
string (default "")
local to buffer
{not available when compiled without the +eval
feature}
```

Expression which is evaluated to obtain the proper indent for a line. It is used when a new line is created, for the `=` operator and in Insert mode as specified with the **'indentkeys'** option.

When this option is not empty, it overrules the **'cindent'** and **'smartindent'** indenting. When **'lisp'** is set, this option is only used when **'lispoptions'** contains "expr:1".

When **'paste'** is set this option is not used for indenting.

The expression is evaluated with `v:lnum` set to the line number for which the indent is to be computed. The cursor is also in this line when the expression is evaluated (but it may be moved around).

If the expression starts with `s:` or `<SID>`, then it is replaced with the script ID ( `local-function` ). Example:

```
set indentexpr=s:MyIndentExpr()
set indentexpr=<SID>SomeIndentExpr()
```

Otherwise, the expression is evaluated in the context of the script where the option was set, thus script-local items are available.

The advantage of using a function call without arguments is that it is faster, see [expr-option-function](#) .

The expression must return the number of spaces worth of indent. It can return "-1" to keep the current indent (this means **'autoindent'** is used for the indent).

Functions useful for computing the indent are `indent()` , `cindent()` and `lispindent()` .

The evaluation of the expression must not have side effects! It must not change the text, jump to another window, etc. Afterwards the cursor position is always restored, thus the cursor may be moved.

Normally this option would be set to call a function:

```
:set indentexpr=GetMyIndent()
```

Error messages will be suppressed, unless the **'debug'** option contains "msg".

See [indent-expression](#) .

**NOTE:** This option is set to "" when **'compatible'** is set.

The expression will be evaluated in the `sandbox` when set from a modeline, see [sandbox-option](#) .

This option cannot be set in a modeline when **'modelineexpr'** is off.

It is not allowed to change text or jump to another window while evaluating **'indentexpr'** `textlock` .

```
'indentkeys' 'indk' 'indentkeys' 'indk'
string (default "0{,0},0),0],:,0#,!^F,o,O,e")
local to buffer
```

A list of keys that, when typed in Insert mode, cause reindenting of the current line. Only happens if **'indentexpr'** isn't empty.

The format is identical to **'cinkeys'**, see [indentkeys-format](#) .

See [C-indenting](#) and [indent-expression](#) .

```
'infercase' 'inf' 'infercase' 'noinfercase' 'noinf'
boolean (default off)
local to buffer
```

When doing keyword completion in insert mode [ins-completion](#) , and **'ignorecase'** is also on, the case of the match is adjusted depending on the typed text. If the typed text contains a lowercase letter where the match has an upper case letter, the completed part is made lowercase. If the typed text has no lowercase letters and the match has a lowercase letter where the typed text has an uppercase letter, and there is a letter before it, the completed part is made uppercase. With **'noinfercase'** the match is used as-is.

```
'insertmode' 'im' 'insertmode' 'im' 'noinsertmode' 'noim'
boolean (default off)
global
```

Makes Vim work in a way that Insert mode is the default mode. Useful if you want to use Vim as a modeless editor. Used for [evim](#) .

These Insert mode commands will be useful:

- Use the cursor keys to move around.
- Use **CTRL-O** to execute one Normal mode command `i_CTRL-O`. When this is a mapping, it is executed as if `'insertmode'` was off. Normal mode remains active until the mapping is finished.
- Use **CTRL-L** to execute a number of Normal mode commands, then use `<Esc>` to get back to Insert mode. Note that **CTRL-L** moves the cursor left, like `<Esc>` does when `'insertmode'` isn't set. `i_CTRL-L`

These items change when `'insertmode'` is set:

- when starting to edit of a file, Vim goes to Insert mode.
- `<Esc>` in Insert mode is a no-op and beeps.
- `<Esc>` in Normal mode makes Vim go to Insert mode.
- **CTRL-L** in Insert mode is a command, it is not inserted.
- **CTRL-Z** in Insert mode suspends Vim, see `CTRL-Z`. `i_CTRL-Z`

However, when `<Esc>` is used inside a mapping, it behaves like `'insertmode'` was not set. This was done to be able to use the same mappings with `'insertmode'` set or not set.

When executing commands with `:normal` `'insertmode'` is not used.

**NOTE:** This option is reset when `'compatible'` is set.

```

'isfname' 'isf'
 'isfname' 'isf'
string (default for Win32:
 "@,48-57,/,\,.,-,_+,,#,$,%,{,},[,],:,@-@,!,~,="
 for AMIGA: "@,48-57,/,\,.,-,_+,,$,:"
 for VMS: "@,48-57,/,\,.,-,_+,,#,$,%,<,>[,],:;,~"
 for OS/390: "@,240-249,/,\,.,-,_+,,#,$,%,~,="
 otherwise: "@,48-57,/,\,.,-,_+,,#,$,%,~,=")
global

```

The characters specified by this option are included in file names and path names. Filenames are used for commands like `"gf"`, `"[i"` and in the tags file. It is also used for `"\f"` in a `pattern`.

Multi-byte characters 256 and above are always included, only the characters up to 255 are specified with this option.

For UTF-8 the characters `0xa0` to `0xff` are included as well.

Think twice before adding white space to this option. Although a space may appear inside a file name, the effect will be that Vim doesn't know where a file name starts or ends when doing completion. It most likely works better without a space in `'isfname'`.

**Note** that on systems using a backslash as path separator, Vim tries to do its best to make it work as you would expect. That is a bit tricky, since Vi originally used the backslash to escape special characters. Vim will not remove a backslash in front of a normal file name character on these systems, but it will on Unix and alikes. The `'&'` and `'^'` are not included by default, because these are special for `cmd.exe`.

The format of this option is a list of parts, separated with commas. Each part can be a single character number or a range. A range is two character numbers with `'-'` in between. A character number can be a decimal number between 0 and 255 or the ASCII character itself (does not work for digits). Example:

```
"_,-,128-140,#-43" (include '_' and '-' and the range
```

128 to 140 and '#' to 43)

If a part starts with '^', the following character number or range will be excluded from the option. The option is interpreted from left to right. Put the excluded character after the range where it is included. To include '^' itself use it as the last character of the option or the end of a range. Example:

```
"^a-z,#,^" (exclude 'a' to 'z', include '#' and '^')
```

If the character is '@', all characters where `isalpha()` returns TRUE are included. Normally these are the characters a to z and A to Z, plus accented characters. To include '@' itself use "@-@". Examples:

```
"@,^a-z" All alphabetic characters, excluding lower case ASCII letters.
```

```
"a-z,A-Z,@-@" All letters plus the '@' character.
```

A comma can be included by using it where a character number is expected. Example:

```
"48-57,,,_-" Digits, comma and underscore.
```

A comma can be excluded by prepending a '^'. Example:

```
" ~,^,,9" All characters from space to '~', excluding comma, plus <Tab>.
```

See [option-backslash](#) about including spaces and backslashes.

```
'isident' 'isi' string (default for Win32:
 '@,48-57,_,128-167,224-235"
 otherwise: "@,48-57,_,192-255")
 global
```

The characters given by this option are included in identifiers. Identifiers are used in recognizing environment variables and after a match of the **'define'** option. It is also used for "\i" in a [pattern](#). See **'isfname'** for a description of the format of this option. For '@' only characters up to 255 are used. Careful: If you change this option, it might break expanding environment variables. E.g., when '/' is included and Vim tries to expand "\$HOME/.viminfo". Maybe you should change **'iskeyword'** instead.

```
'iskeyword' 'isk' string (Vim default for Win32:
 '@,48-57,_,128-167,224-235"
 otherwise: "@,48-57,_,192-255"
 Vi default: "@,48-57,_"
 local to buffer
```

Keywords are used in searching and recognizing with many commands: "w", "\*", "[i", etc. It is also used for "\k" in a [pattern](#). See **'isfname'** for a description of the format of this option. For '@' characters above 255 check the "word" character class (any character that is not white space or punctuation).

For C programs you could use "a-z,A-Z,48-57,\_,.,-,>".

For a help file it is set to all non-blank printable characters except '\*', '' and '|' (so that **CTRL-]** on a command finds the help for that command).

When the **'lisp'** option is on the '-' character is always included.

This option also influences syntax highlighting, unless the syntax uses `:syn-iskeyword`.

**NOTE:** This option is set to the Vi default value when **'compatible'** is

set and to the Vim default value when **'compatible'** is reset.

**'isprint' 'isp'** string (default for Win32 and VMS: **'isprint' 'isp'**  
" @,~-255"; otherwise: " @,161-255")  
global

The characters given by this option are displayed directly on the screen. It is also used for "\p" in a **pattern**. The characters from space (ASCII 32) to '~' (ASCII 126) are always displayed directly, even when they are not included in **'isprint'** or excluded. See **'isfname'** for a description of the format of this option.

Non-printable characters are displayed with two characters:

0 - 31	"^@" - "^_"
32 - 126	always single characters
127	"^?"
128 - 159	"~@" - "~_"
160 - 254	"  " - " ~"
255	"~?"

When **'encoding'** is a Unicode one, illegal bytes from 128 to 255 are displayed as **<xx>**, with the hexadecimal value of the byte.

When **'display'** contains "uhex" all unprintable characters are displayed as **<xx>**.

The SpecialKey highlighting will be used for unprintable characters.  
**hl-SpecialKey**

Multi-byte characters 256 and above are always included, only the characters up to 255 are specified with this option. When a character is printable but it is not available in the current font, a replacement character will be shown.

Unprintable and zero-width Unicode characters are displayed as **<xxxx>**. There is no option to specify these characters.

**'joinspaces' 'js'** **'joinspaces' 'js' 'nojoinspaces' 'nojs'**  
boolean (default on)  
global

Insert two spaces after a '.', '!' and '!' with a join command.

When **'coptions'** includes the 'j' flag, only do this after a '.'.

Otherwise only one space is inserted.

**NOTE:** This option is set when **'compatible'** is set.

**'jumptions' 'jop'** **'jumptions' 'jop'**  
string (default "")  
global

List of words that change the behavior of the **jumplist**.

stack Make the jumplist behave like the tagstack.

Relative location of entries in the jumplist is preserved at the cost of discarding subsequent entries when navigating backwards in the jumplist and then jumping to a location. **jumplist-stack**

**'key'** **'key'**  
string (default "")  
local to buffer

{only available when compiled with the `+cryptv` feature}

The key that is used for encrypting and decrypting the current buffer. See [encryption](#) and `'cryptmethod'`.

Careful: Do not set the key value by hand, someone might see the typed key. Use the `:X` command. But you can make `'key'` empty:

```
:set key=
```

It is not possible to get the value of this option with `":set key"` or `"echo &key"`. This is to avoid showing it to someone who shouldn't know. It also means you cannot see it yourself once you have set it, be careful not to make a typing error!

You also cannot use `:set-=`, `:set+=`, `:set^=` on this option to prevent an attacker from guessing substrings in your key.

You can use `"&key"` in an expression to detect whether encryption is enabled. When `'key'` is set it returns `"*****"` (five stars).

```
'keymap' 'kmp' 'keymap' 'kmp' E544
 string (default "")
 local to buffer
 {only available when compiled with the +keymap
 feature}
```

Name of a keyboard mapping. See [mbyte-keymap](#).

Setting this option to a valid keymap name has the side effect of setting `'iminsert'` to one, so that the keymap becomes effective.

`'imsearch'` is also set to one, unless it was `-1`

Only alphanumeric characters, `'.'`, `'-'` and `'_'` can be used.

```
'keymodel' 'km' 'keymodel' 'km'
 string (default "")
 global
```

List of comma-separated words, which enable special things that keys can do. These values can be used:

`startsel` Using a shifted special key starts selection (either Select mode or Visual mode, depending on `"key"` being present in `'selectmode'`).

`stopsel` Using a not-shifted special key stops selection.

Special keys in this context are the cursor keys, `<End>`, `<Home>`, `<PageUp>` and `<PageDown>`.

The `'keymodel'` option is set by the `:behave` command.

```
'keyprotocol' 'kpc' 'keyprotocol' 'kpc'
 string (default: see below)
 global
```

Specifies what keyboard protocol to use depending on the value of `'term'`. The supported keyboard protocols names are:

`none` whatever the terminal uses

`mok2` modifyOtherKeys level 2, as supported by xterm

`kitty` Kitty keyboard protocol, as supported by Kitty

The option value is a list of comma separated items. Each item has a pattern that is matched against the `'term'` option, a colon and the protocol name to be used. To illustrate this, the default value would be set with:

```
set keyprotocol=kitty:kitty,foot:kitty,ghostty:kitty,wezterm:kitty
```

```
set keyprotocol+=xterm:mok2
```

This means that when **'term'** contains "kitty", "foot", "ghostty" or "wezterm" somewhere, then the "kitty" protocol is used. When **'term'** contains "xterm" somewhere, then the "mok2" protocol is used.

The first match is used, thus if you want to have "kitty" use the kitty protocol, but "badkitty" not, then you should match "badkitty" first and use the "none" value:

```
set keyprotocol=badkitty:none,kitty:kitty
```

The option is used after **'term'** has been changed. First the termcap entries are set, possibly using the builtin list, see [builtin-terms](#) . Then this option is inspected and if there is a match and a protocol is specified the following happens:

```
none Nothing, the regular t_TE and t_TI values remain

mok2 The t_TE value is changed to:
 CSI >4;m disables modifyOtherKeys
 The t_TI value is changed to:
 CSI >4;2m enables modifyOtherKeys
 CSI ?4m request the modifyOtherKeys state

kitty The t_TE value is changed to:
 CSI >4;m disables modifyOtherKeys
 CSI =0;1u disables the kitty keyboard protocol
 The t_TI value is changed to:
 CSI =1;1u enables the kitty keyboard protocol
 CSI ?u request kitty keyboard protocol state
 CSI >c request the termresponse
```

If you notice problems, such as characters being displayed that disappear after ``CTRL-L``, you might want to try making this option empty. Then set the **'term'** option to have it take effect:

```
set keyprotocol=
let &term = &term
```

```
'keywordprg' 'kp' 'keywordprg' 'kp'
 string (default "man" or "man -s", DOS: ":help",
 VMS: "help")
 global or local to buffer global-local
```

Program to use for the **K** command. Environment variables are expanded `:set_env` . ":help" may be used to access the Vim internal help. (Note that previously setting the global option to the empty value did this, which is now deprecated.)

When the first character is ":", the command is invoked as a Vim Ex command with `[count]` added as an argument if it is not zero.

When "man", "man -s" or an Ex command is used, Vim will automatically translate a count for the "K" command and pass it as the first argument. For "man -s" the "-s" is removed when there is no count. See [option-backslash](#) about including spaces and backslashes.

Example:

```
:set keywordprg=man\ -s
```

This option cannot be set from a `modeline` or in the `sandbox`, for security reasons.

```
'langmap' 'lmap' 'langmap' 'lmap' E357 E358
string (default "")
global
{only available when compiled with the +langmap
feature}
```

This option allows switching your keyboard into a special language mode. When you are typing text in Insert mode the characters are inserted directly. When in Normal mode the `'langmap'` option takes care of translating these special characters to the original meaning of the key. This means you don't have to change the keyboard mode to be able to execute Normal mode commands.

This is the opposite of the `'keymap'` option, where characters are mapped in Insert mode.

Also consider setting `'langremap'` to off, to prevent `'langmap'` from applying to characters resulting from a mapping.

This option cannot be set from a `modeline` or in the `sandbox`, for security reasons.

Example (for Greek, in UTF-8):

```
:set langmap=␣A,␣B,␣C,␣D,␣E,␣F,␣G,␣H,␣I,␣J,␣K,␣L,␣M,␣N,␣O,␣P,␣Q,␣R,␣S,␣T,␣U,␣V
```

Example (exchanges meaning of z and y for commands):

```
:set langmap=zy,yz,ZY,YZ
```

The `'langmap'` option is a list of parts, separated with commas. Each part can be in one of two forms:

1. A list of pairs. Each pair is a "from" character immediately followed by the "to" character. Examples: "aA", "aAbBcC".
2. A list of "from" characters, a semicolon and a list of "to" characters. Example: "abc;ABC"

Example: "aA, fgh;FGH, cCdDeE"

Special characters need to be preceded with a backslash. These are `";"`, `'`, `'`, `'`, `'|'` and backslash itself.

This will allow you to activate vim actions without having to switch back and forth between the languages. Your language characters will be understood as normal vim English characters (according to the langmap mappings) in the following cases:

- o Normal/Visual mode (commands, buffer/register names, user mappings)
- o Insert/Replace Mode: Register names after **CTRL-R**
- o Insert/Replace Mode: Mappings

Characters entered in Command-line mode will NOT be affected by this option. **Note** that this option can be changed at any time allowing to switch between mappings for different languages/encodings. Use a mapping to avoid having to type it each time!

```
'langmenu' 'lm' 'langmenu' 'lm'
string (default "")
global
{only available when compiled with the +menu and
+multi_lang features}
```

Language to use for menu translation. Tells which file is loaded

from the "lang" directory in `'runtimepath'`:  
`"lang/menu_" .. &langmenu .. ".vim"`  
(without the spaces). For example, to always use the Dutch menus, no matter what \$LANG is set to:

```
:set langmenu=nl_NL.ISO_8859-1
```

When `'langmenu'` is empty, `v:lang` is used.

Only normal file name characters can be used, `"/*?[]<>"` are illegal. If your \$LANG is set to a non-English language but you do want to use the English menus:

```
:set langmenu=none
```

This option must be set before loading menus, switching on filetype detection or syntax highlighting. Once the menus are defined setting this option has no effect. But you could do this:

```
:source $VIMRUNTIME/delmenu.vim
:set langmenu=de_DE.ISO_8859-1
:source $VIMRUNTIME/menu.vim
```

Warning: This deletes all menus that you defined yourself!

```
'langnoremap' 'lnr' 'langnoremap' 'lnr' 'nolangnoremap' 'nolnr'
boolean (default off, set in defaults.vim)
global
{only available when compiled with the +langmap
feature}
```

This is just like `'langremap'` but with the value inverted. It only exists for backwards compatibility. When setting `'langremap'` then `'langnoremap'` is set to the inverted value, and the other way around.

```
'langremap' 'lrm' 'langremap' 'lrm' 'nolangremap' 'nolrm'
boolean (default on, set to off in defaults.vim)
global
{only available when compiled with the +langmap
feature}
```

When off, setting `'langmap'` does not apply to characters resulting from a mapping. This basically means, if you noticed that setting `'langmap'` disables some of your mappings, try resetting this option. This option defaults to on for backwards compatibility. Set it off if that works for you to avoid mappings to break.

```
'laststatus' 'ls' 'laststatus' 'ls'
number (default 1)
global
```

The value of this option influences when the last window will have a status line:

```
0: never
1: only if there are at least two windows
2: always
```

The screen looks nicer with a status line if you have several windows, but it takes another screen line. [status-line](#)

```
'lazyredraw' 'lz' 'lazyredraw' 'lz' 'nolazyredraw' 'nolz'
boolean (default off)
global
```

When this option is set, the screen will not be redrawn while executing macros, registers and other commands that have not been

typed. Also, updating the window title is postponed. To force an update use `:redraw`. This may occasionally cause display errors. It is only meant to be set temporarily when performing an operation where redrawing may cause flickering or cause a slowdown.

**'linebreak'** **'lbr'** **'linebreak'** **'lbr'** **'nolinebreak'** **'nolbr'**  
boolean (default off)  
local to window  
{not available when compiled without the `+linebreak` feature}

If on, Vim will wrap long lines at a character in **'breakat'** rather than at the last character that fits on the screen. Unlike **'wrapmargin'** and **'textwidth'**, this does not insert `<EOL>`s in the file, it only affects the way the file is displayed, not its contents. If **'breakindent'** is set, line is visually indented. Then, the value of **'showbreak'** is used to put in front of wrapped lines. This option is not used when the **'wrap'** option is off.  
**Note** that `<Tab>` characters after an `<EOL>` are mostly not displayed with the right amount of white space.

**'lines'** **'lines'** **E593**  
number (default 24 or terminal height)  
global

Number of lines of the Vim window. Normally you don't need to set this. It is done automatically by the terminal initialization code. Also see `posix-screen-size`. When Vim is running in the GUI or in a resizable window, setting this option will cause the window size to be changed. When you only want to use the size for the GUI, put the command in your `gvimrc` file. Vim limits the number of lines to what fits on the screen. You can use this command to get the tallest window possible:

```
:set lines=999
```

Minimum value is 2, maximum value is 1000.

If you get fewer lines than expected, check the **'guiheadroom'** option. When you set this option and Vim is unable to change the physical number of lines of the display, the display may be messed up.

**'linespace'** **'lsp'** **'linespace'** **'lsp'**  
number (default 0, 1 for Win32 GUI)  
global  
{only in the GUI}

Number of pixel lines inserted between characters. Useful if the font uses the full character cell height, making lines touch each other. When non-zero there is room for underlining. With some fonts there can be too much room between lines (to have space for ascents and descents). Then it makes sense to set **'linespace'** to a negative value. This may cause display problems though!

**'lisp'** **'lisp'** **'nolisp'**  
boolean (default off)  
local to buffer  
Lisp mode: When `<Enter>` is typed in insert mode set the indent for

the next line to Lisp standards (well, sort of). Also happens with "cc" or "S". **'autoindent'** must also be on for this to work. The 'p' flag in **'coptions'** changes the method of indenting: Vi compatible or better. Also see **'lispwords'**.

The '-' character is included in keyword characters. Redefines the "=" operator to use this same indentation algorithm rather than calling an external program if **'equalprg'** is empty. This option is not used when **'paste'** is set.

**'lispoptions'** **'lop'** string (default "")  
local to buffer

Comma-separated list of items that influence the Lisp indenting when enabled with the **'lisp'** option. Currently only one item is supported:

expr:1 use **'indentexpr'** for Lisp indenting when it is set  
expr:0 do not use **'indentexpr'** for Lisp indenting (default)

**Note** that when using **'indentexpr'** the '=' operator indents all the lines, otherwise the first line is not indented (Vi-compatible).

**'lispwords'** **'lw'** string (default is very long)  
global or local to buffer **global-local**

Comma-separated list of words that influence the Lisp indenting when enabled with the **'lisp'** option.

**'list'** boolean (default off)  
local to window

List mode: By default show tabs as **CTRL-I** is displayed, display \$ after end of line. Useful to see the difference between tabs and spaces and for trailing blanks. Further changed by the **'listchars'** option.

The cursor is displayed at the start of the space a Tab character occupies, not at the end as usual in Normal mode. To get this cursor position while displaying Tabs with spaces, use:

```
:set list lcs=tab:\ \
```

**Note** that list mode will also affect formatting (set with **'textwidth'** or **'wrapmargin'**) when **'coptions'** includes 'L'. See **'listchars'** for changing the way tabs are displayed.

**'listchars'** **'lcs'** string (default "eol:\$")  
global or local to window **global-local**

Strings to use in **'list'** mode and for the **:list** command. It is a comma-separated list of string settings. **E1511**

**eol:c** Character to show at the end of each line. When omitted, there is no extra character at the end of the line.

**tab:xy[z]** Two or three characters to be used to show a tab.

The third character is optional.

`tab:xy` The 'x' is always used, then 'y' as many times as will fit. Thus "`tab:>-`" displays:

```
>
>-
>--
etc.
```

`tab:xyz` The 'z' is always used, then 'x' is prepended, and then 'y' is used as many times as will fit. Thus "`tab:<->`" displays:

```
>
<>
<->
<-->
etc.
```

When "`tab:`" is omitted, a tab is shown as `^I`.

`space:c` Character to show for a space. When omitted, spaces are left blank.

`lcs-multispace`

`multispace:c...`

One or more characters to use cyclically to show for multiple consecutive spaces. Overrides the "`space`" setting, except for single spaces. When omitted, the "`space`" setting is used. For example, ``:set listchars=multispace:----+`` shows ten consecutive spaces as:

```
----+----+---
```

`lcs-lead`

`lead:c` Character to show for leading spaces. When omitted, leading spaces are blank. Overrides the "`space`" and "`multispace`" settings for leading spaces. You can combine it with "`tab:`", for example:

```
:set listchars+=tab:>- ,lead:.
```

`lcs-leadmultispace`

`leadmultispace:c...`

Like the `lcs-multispace` value, but for leading spaces only. Also overrides `lcs-lead` for leading multiple spaces.

``:set listchars=leadmultispace:----+`` shows ten consecutive leading spaces as:

```
----+----+---XXX
```

Where "XXX" denotes the first non-blank characters in the line.

`lcs-trail`

`trail:c` Character to show for trailing spaces. When omitted, trailing spaces are blank. Overrides the "`space`" and "`multispace`" settings for trailing spaces.

`lcs-extends`

`extends:c` Character to show in the last column, when '`wrap`' is off and the line continues beyond the right of the

screen.

		<code>lcs-precedes</code>
<code>precedes:c</code>	Character to show in the first visible column of the physical line, when there is text preceding the character visible in the first column.	
		<code>lcs-conceal</code>
<code>conceal:c</code>	Character to show in place of concealed text, when <code>'conceallevel'</code> is set to 1.	
		<code>lcs-nbsp</code>
<code>nbsp:c</code>	Character to show for a non-breakable space character (0xA0 (160 decimal) and U+202F). Left blank when omitted.	

The characters ':' and ',' should not be used. UTF-8 characters can be used when `'encoding'` is "utf-8", otherwise only printable characters are allowed. All characters must be single width. E1512

Each character can be specified as hex:

```
set listchars=eol:\x24
set listchars=eol:\u21b5
set listchars=eol:\U000021b5
```

Note that a double backslash is used. The number of hex characters must be exactly 2 for `\\x`, 4 for `\\u` and 8 for `\\U`.

Examples:

```
:set lcs=tab:>-,trail:-
:set lcs=tab:>-,eol:<,nbsp:%
:set lcs=extends:>,precedes:<
```

The "NonText" highlighting will be used for "eol", "extends" and "precedes". "SpecialKey" will be used for "tab", "nbsp", "space", "multispace", "lead" and "trail".

```
hl-NonText hl-SpecialKey
```

		<code>'lpl'</code>	<code>'nolpl'</code>	<code>'loadplugins'</code>	<code>'noloadplugins'</code>
<code>'loadplugins'</code>	<code>'lpl'</code>	boolean (default on)			
		global			

When on the plugin scripts are loaded when starting up `load-plugins`. This option can be reset in your `vimrc` file to disable the loading of plugins.

Note that using the `"-u NONE"`, `"-u DEFAULTS"` and `"--noplugin"` command line arguments reset this option. See `-u` and `--noplugin`.

		<code>'luadll'</code>
<code>'luadll'</code>	string (default depends on the build)	
	global	
	{only available when compiled with the <code>+lua/dyn</code> feature}	

Specifies the name of the Lua shared library. The default is `DYNAMIC_LUA_DLL`, which was specified at compile time.

Environment variables are expanded `:set_env`.

This option cannot be set from a `modeline` or in the `sandbox`, for security reasons.

		<code>'macatsui'</code>	<code>'nomacatsui'</code>
--	--	-------------------------	---------------------------

**'macatsui'**                   boolean (default on)  
                               global  
                               {not supported}  
 No longer supported, as the Mac OS X GUI code was removed.

**'magic'**                    boolean (default on)  
                               global  
 Changes the special characters that can be used in search patterns.  
 See [pattern](#) .  
 WARNING: Switching this option off most likely breaks plugins! That is because many patterns assume it's on and will fail when it's off. Only switch it off when working with old Vi scripts. In any other situation write patterns that work when **'magic'** is on. Include "\M" when you want to `/\M` .  
 In `Vim9` script the value of **'magic'** is ignored, patterns behave like it is always set.

**'makeef'** **'mef'**           string (default: "")  
                               global  
                               {not available when compiled without the `+quickfix` feature}  
 Name of the errorfile for the `:make` command (see `:make_makeprg` ) and the `:grep` command.  
 When it is empty, an internally generated temp file will be used. When "##" is included, it is replaced by a number to make the name unique. This makes sure that the ":make" command doesn't overwrite an existing file.  
 NOT used for the `:cf`" command. See **'errorfile'** for that.  
 Environment variables are expanded `:set_env` .  
 See [option-backslash](#) about including spaces and backslashes.  
 This option cannot be set from a `modeline` or in the `sandbox` , for security reasons.

**'makeencoding'** **'menc'**   string (default "")  
                               global or local to buffer `global-local`  
 Encoding used for reading the output of external commands. When empty, encoding is not converted.  
 This is used for `:make`, `:lmake`, `:grep`, `:lgrep`, `:grepadd`, `:lgrepadd`, `:cfile`, `:cgetfile`, `:caddfile`, `:lfile`, `:lgetfile`, and `:laddfile` .  
 This would be mostly useful when you use MS-Windows and set **'encoding'** to "utf-8". If `+iconv` is enabled and GNU libiconv is used, setting **'makeencoding'** to "char" has the same effect as setting to the system locale encoding. Example:  
`:set encoding=utf-8`  
`:set makeencoding=char " system locale is used`

**'makeprg'** **'mp'**           string (default "make", VMS: "MMS")  
                               global or local to buffer `global-local`

Program to use for the `:"make"` command. See `:make_makeprg`. This option may contain `'%'` and `'#'` characters (see `:_%` and `:_#`), which are expanded to the current and alternate file name. Use `::S` to escape file names in case they contain special characters. Environment variables are expanded `:set_env`. See `option-backslash` about including spaces and backslashes.

**Note** that a `'|'` must be escaped twice: once for `:"set"` and once for the interpretation of a command. When you use a filter called `"myfilter"` do it like this:

```
:set makeprg=gmake\ \\\| myfilter
```

The placeholder `"$*"` can be given (even multiple times) to specify where the arguments will be included, for example:

```
:set makeprg=latex\ \\\nonstopmode\ \\\input\\{$*}
```

This option cannot be set from a `modeline` or in the `sandbox`, for security reasons.

```
'matchpairs' 'mps' string (default "(:),{:},[:]")
 local to buffer
```

Characters that form pairs. The `%` command jumps from one to the other.

Only character pairs are allowed that are different, thus you cannot jump between two double quotes.

The characters must be separated by a colon.

The pairs must be separated by a comma. Example for including `'<'` and `'>'` (for HTML):

```
:set mps+=<>
```

A more exotic example, to jump between the `'='` and  `';'`  in an assignment, useful for languages like C and Java:

```
:au FileType c,cpp,java set mps+=:=;
```

For a more advanced way of using `"%"`, see the `matchit.vim` plugin in the `$VIMRUNTIME/pack/dist/opt/matchit` directory. [add-local-help](#)

```
'matchtime' 'mat' number (default 5)
 global
```

Tenths of a second to show the matching paren, when `'showmatch'` is set. **Note** that this is not in milliseconds, like other options that set a time. This is to be compatible with `Nvi`.

```
'maxcombine' 'mco' number (default 2)
 global
```

The maximum number of combining characters supported for displaying. Only used when `'encoding'` is `"utf-8"`.

The default is OK for most languages. Hebrew may require 4.

Maximum value is 6.

Even when this option is set to 2 you can still edit text with more combining characters, you just can't see them. Use `g8` or `ga`.

See [mbyte-combining](#).

```
'maxfuncdepth' 'mfd'
```

**'maxfuncdepth'** **'mfd'**      number (default 100)  
                                 global  
                                 {not available when compiled without the `+eval`  
                                 feature}

Maximum depth of function calls for user functions. This normally catches endless recursion. When using a recursive function with more depth, set **'maxfuncdepth'** to a bigger number. But this will use more memory, there is the danger of failing when memory is exhausted. Increasing this limit above 200 also changes the maximum for Ex command recursion, see [E169](#) .

See also `:function` .

Also used for maximum depth of callback functions.

**'maxmapdepth'** **'mmd'**      number (default 1000) **'maxmapdepth'** **'mmd'** [E223](#)  
                                 global

Maximum number of times a mapping is done without resulting in a character to be used. This normally catches endless mappings, like `":map x y"` with `":map y x"`. It still does not catch `":map g wg"`, because the `'w'` is used before the next mapping is done. See also [key-mapping](#) .

**'maxmem'** **'mm'**              number (default between 256 to 5120 (system  
                                 dependent) or half the amount of memory  
                                 available)  
                                 global

Maximum amount of memory (in Kbyte) to use for one buffer. When this limit is reached allocating extra memory for a buffer will cause other memory to be freed.

The maximum usable value is about 2000000. Use this to work without a limit.

The value is ignored when **'swapfile'** is off.

Also see **'maxmemtot'** .

**'maxmempattern'** **'mmp'**      number (default 1000) **'maxmempattern'** **'mmp'**  
                                 global

Maximum amount of memory (in Kbyte) to use for pattern matching. The maximum value is about 2000000. Use this to work without a limit.

[E363](#)

When Vim runs into the limit it gives an error message and mostly behaves like **CTRL-C** was typed.

Running into the limit often means that the pattern is very inefficient or too complex. This may already happen with the pattern `"\(.\)*"` on a very long line. `".*"` works much better.

Might also happen on redraw, when syntax rules try to match a complex text structure.

Vim may run out of memory before hitting the **'maxmempattern'** limit, in which case you get an "Out of memory" error instead.

**'maxmemtot'** **'mmt'**          number (default between 2048 and 10240 (system  
                                 dependent) or half the amount of memory

available)

global

Maximum amount of memory in Kbyte to use for all buffers together. The maximum usable value is about 2000000 (2 Gbyte). Use this to work without a limit.

On 64 bit machines higher values might work. But hey, do you really need more than 2 Gbyte for text editing? Keep in mind that text is stored in the swap file, one can edit files > 2 Gbyte anyway. We do need the memory to store undo info.

Buffers with **'swapfile'** off still count to the total amount of memory used.

Also see **'maxmem'**.

**'menuitems'** **'mis'** **'menuitems'** **'mis'**  
number (default 25)  
global  
{not available when compiled without the **+menu**  
feature}

Maximum number of items to use in a menu. Used for menus that are generated from a list of items, e.g., the Buffers menu. Changing this option has no direct effect, the menu must be refreshed first.

**'messagesopt'** **'mopt'** **'messagesopt'** **'mopt'**  
string (default "hit-enter,history:500")  
global

Option settings for outputting messages. It can consist of the following items. Items must be separated by a comma.

**hit-enter** Use a **hit-enter** prompt when the message is longer than **'cmdheight'** size.

**wait:{n}** Instead of using a **hit-enter** prompt, simply wait for **{n}** milliseconds so that the user has a chance to read the message. The maximum value of **{n}** is 10000. Use 0 to disable the wait (but then the user may miss an important message).  
This item is ignored when "hit-enter" is present, but required when "hit-enter" is not present.

**history:{n}** Determines how many entries are remembered in the **:messages** history. The maximum value is 10000. Setting it to zero clears the message history.  
This item must always be present.

**'mkspellmem'** **'msm'** **'mkspellmem'** **'msm'**  
string (default "460000,2000,500")  
global  
{not available when compiled without the **+syntax**  
feature}

Parameters for **:mkspell**. This tunes when to start compressing the word tree. Compression can be slow when there are many words, but it's needed to avoid running out of memory. The amount of memory used per word depends very much on how similar the words are, that's why

this tuning is complicated.

There are three numbers, separated by commas:

```
{start},{inc},{added}
```

For most languages the uncompressed word tree fits in memory. `{start}` gives the amount of memory in Kbyte that can be used before any compression is done. It should be a bit smaller than the amount of memory that is available to Vim.

When going over the `{start}` limit the `{inc}` number specifies the amount of memory in Kbyte that can be allocated before another compression is done. A low number means compression is done after less words are added, which is slow. A high number means more memory will be allocated.

After doing compression, `{added}` times 1024 words can be added before the `{inc}` limit is ignored and compression is done when any extra amount of memory is needed. A low number means there is a smaller chance of hitting the `{inc}` limit, less memory is used but it's slower.

The languages for which these numbers are important are Italian and Hungarian. The default works for when you have about 512 Mbyte. If you have 1 Gbyte you could use:

```
:set mkspellmem=900000,3000,800
```

If you have less than 512 Mbyte `:mkspell` may fail for some languages, no matter what you set `'mkspellmem'` to.

This option cannot be set from a `modeline` or in the `sandbox`, for security reasons.

```
'modeline' 'ml' 'modeline' 'ml' 'nomodeline' 'noml'
boolean (Vim default: on (off for root),
Vi default: off)
local to buffer
```

If `'modeline'` is on `'modelines'` gives the number of lines that is checked for set commands. If `'modeline'` is off or `'modelines'` is zero no lines are checked. See `modeline`.

```
'modelineexpr' 'mle' 'modelineexpr' 'mle' 'nomodelineexpr' 'nomle'
boolean (default: off)
global
```

When on allow some options that are an expression to be set in the `modeline`. Check the option for whether it is affected by `'modelineexpr'`. Also see `modeline`.

This option cannot be set from a `modeline` or in the `sandbox`, for security reasons.

```
'modelines' 'mls' 'modelines' 'mls'
number (default 5)
global
```

If `'modeline'` is on `'modelines'` gives the number of lines that is checked for set commands. If `'modeline'` is off or `'modelines'` is zero

no lines are checked. See [modeline](#) .

**NOTE:** `'modeline'` is set to the Vi default value when `'compatible'` is set and to the Vim default value when `'compatible'` is reset.

`'modifiable'`   `'ma'`   `'nomodifiable'`   `'noma'`  
E21

**'modifiable'** `'ma'`        boolean (default on)  
                          local to buffer

When off the buffer contents cannot be changed. The `'fileformat'` and `'fileencoding'` options also can't be changed.

Can be reset on startup with the `-M` command line argument.

`'modified'`   `'mod'`   `'nomodified'`   `'nomod'`

**'modified'** `'mod'`        boolean (default off)  
                          local to buffer   `local-noglobal`

When on, the buffer is considered to be modified. This option is set when:

1. A change was made to the text since it was last written. Using the `undo` command to go back to the original text will reset the option. But undoing changes that were made before writing the buffer will set the option again, since the text is different from when it was written.
2. `'fileformat'` or `'fileencoding'` is different from its original value. The original value is set when the buffer is read or written. A `":set nomodified"` command also resets the original values to the current values and the `'modified'` option will be reset.

Similarly for `'eol'` and `'bomb'`.

This option is not set when a change is made to the buffer as the result of a `BufNewFile`, `BufRead/BufReadPost`, `BufWritePost`, `FileAppendPost` or `VimLeave` autocommand event. See [gzip-example](#) for an explanation.

When `'buftype'` is `"nowrite"` or `"nofile"` this option may be set, but will be ignored.

**Note** that the text may actually be the same, e.g. `'modified'` is set when using `"rA"` on an `"A"`.

`'more'`   `'nomore'`

**'more'**                    boolean (Vim default: on, Vi default: off)  
                          global

When on, listings pause when the whole screen is filled. You will get the `more-prompt` . When this option is off there are no pauses, the listing continues until finished.

**NOTE:** This option is set to the Vi default value when `'compatible'` is set and to the Vim default value when `'compatible'` is reset.

`'mouse'`

**'mouse'**                    string (default "", "a" for GUI and Win32,  
                                          set to "a" or "nvi" in [defaults.vim](#) )  
                          global

Enable the use of the mouse. Works for most terminals (`xterm`, `Win32` [win32-mouse](#) , `QNX pterm`, `*BSD console` with `sysmouse` and `Linux console` with `gpm`). For using the mouse in the GUI, see [gui-mouse](#) . The mouse can be enabled for different modes:

n	Normal mode and Terminal modes
v	Visual mode
i	Insert mode
c	Command-line mode
h	all previous modes when editing a help file
a	all previous modes
r	for <code>hit-enter</code> and <code>more-prompt</code> prompt

Normally you would enable the mouse in all five modes with:

```
:set mouse=a
```

If your terminal can't overrule the mouse events going to the application, use:

```
:set mouse=nvi
```

Then you can press ":", select text for the system, and press Esc to go back to Vim using the mouse events.

In `defaults.vim` "nvi" is used if the `'term'` option is not matching "xterm".

When the mouse is not enabled, the GUI will still use the mouse for modeless selection. This doesn't move the text cursor.

See `mouse-using` . Also see `'clipboard'` .

**Note:** When enabling the mouse in a terminal, copy/paste will use the "\*" register if there is access to an X-server. The xterm handling of the mouse buttons can still be used by keeping the shift key pressed. Also see the `'clipboard'` option.

	<code>'mousefocus'</code>	<code>'mousef'</code>	<code>'nomousefocus'</code>	<code>'nomousef'</code>
<code>'mousefocus'</code>	<code>'mousef'</code>	boolean (default off)		
		global		
		{only works in the GUI}		

The window that the mouse pointer is on is automatically activated. When changing the window layout or window focus in another way, the mouse pointer is moved to the window with keyboard focus. Off is the default because it makes using the pull down menus a little goofy, as a pointer transit may activate a window unintentionally.

MS-Windows: Also see `'scrollfocus'` for what window is scrolled when using the mouse scroll wheel.

	<code>'mousehide'</code>	<code>'mh'</code>	<code>'nomousehide'</code>	<code>'nomh'</code>
<code>'mousehide'</code>	<code>'mh'</code>	boolean (default on)		
		global		
		{only works in the GUI}		

When on, the mouse pointer is hidden when characters are typed. The mouse pointer is restored when the mouse is moved.

	<code>'mousemodel'</code>	<code>'mousem'</code>
<code>'mousemodel'</code>	<code>'mousem'</code>	string (default "extend", "popup" for Win32)
		global

Sets the model to use for the mouse. The name mostly specifies what the right mouse button is used for:

extend	Right mouse button extends a selection. This works like in an xterm.
popup	Right mouse button pops up a menu. The shifted left

mouse button extends a selection. This works like with Microsoft Windows.

popup\_setpos Like "popup", but the cursor will be moved to the position where the mouse was clicked, and thus the selected operation will act upon the clicked object. If clicking inside a selection, that selection will be acted upon, i.e. no cursor move. This implies of course, that right clicking outside a selection will end Visual mode.

Overview of what button does what for each model:

mouse	extend	popup(_setpos)
left click	place cursor	place cursor
left drag	start selection	start selection
shift-left	search word	extend selection
right click	extend selection	popup menu (place cursor)
right drag	extend selection	-
middle click	paste	paste

In the "popup" model the right mouse button produces a pop-up menu. You need to define this first, see [popup-menu](#) .

**Note** that you can further refine the meaning of buttons with mappings. See [gui-mouse-mapping](#) . But mappings are NOT used for modeless selection (because that's handled in the GUI code directly).

The `'mousemodel'` option is set by the `:behave` command.

```
'mousemoveevent' 'mousemev' 'nomousemoveevent' 'nomousemev'
'mousemoveevent' 'mousemev' boolean (default off)
global
{only works in the GUI}
```

When on, mouse move events are delivered to the input queue and are available for mapping. The default, off, avoids the mouse movement overhead except when needed. See [gui-mouse-mapping](#) .

Warning: Setting this option can make pending mappings to be aborted when the mouse is moved.

Currently only works in the GUI, may be made to work in a terminal later.

```
'moushape' 'mouses' string (default "i-r:beam,s:updown,sd:udsizing,
 vs:left:right,vd:lrsizing,m:no,
 ml:up-arrow,v:rightup-arrow")
global
{only available when compiled with the +moushape
feature}
```

This option tells Vim what the mouse pointer should look like in different modes. The option is a comma-separated list of parts, much like used for `'guicursor'`. Each part consist of a mode/location-list and an argument-list:

```
mode-list:shape,mode-list:shape,..
```

The mode-list is a dash separated list of these modes/locations:

**In a normal window:**

```
n Normal mode
```

v Visual mode  
 ve Visual mode with 'selection' "exclusive" (same as 'v',  
 if not specified)  
 o Operator-pending mode  
 i Insert mode  
 r Replace mode

Others:

c appending to the command-line  
 ci inserting in the command-line  
 cr replacing in the command-line  
 m at the 'Hit ENTER' or 'More' prompts  
 ml idem, but cursor in the last line  
 e any mode, pointer below last window  
 s any mode, pointer on a status line  
 sd any mode, while dragging a status line  
 vs any mode, pointer on a vertical separator line  
 vd any mode, while dragging a vertical separator line  
 a everywhere

The shape is one of the following:

avail	name	looks like
w x	arrow	Normal mouse pointer
w x	blank	no pointer at all (use with care!)
w x	beam	I-beam
w x	updown	up-down sizing arrows
w x	leftright	left-right sizing arrows
w x	busy	The system's usual busy pointer
w x	no	The system's usual 'no input' pointer
x	ud sizing	indicates up-down resizing
x	lrsizing	indicates left-right resizing
x	crosshair	like a big thin +
x	hand1	black hand
x	hand2	white hand
x	pencil	what you write with
x	question	big ?
x	rightup-arrow	arrow pointing right-up
w x	up-arrow	arrow pointing up
x	<number>	any X11 pointer number (see X11/cursorfont.h)

The "avail" column contains a 'w' if the shape is available for Win32, x for X11.

Any modes not specified or shapes not available use the normal mouse pointer.

Example:

```
:set mouseshape=s:ud sizing,m:no
```

will make the mouse turn to a sizing arrow over the status lines and indicate no input when the hit-enter prompt is displayed (since clicking the mouse has no effect in this state.)

```
'mousetime' 'mouset' number (default 500)
 global
 'mousetime' 'mouset'
```

Only for GUI, Win32 and Unix with xterm. Defines the maximum time in msec between two mouse clicks for the second click to be recognized as a multi click.

**'mzquantum'** **'mzq'** **'mzquantum'** **'mzq'**  
number (default 100)  
global  
{not available when compiled without the **+mzscheme**  
feature}

The number of milliseconds between polls for MzScheme threads. Negative or zero value means no thread scheduling.

**NOTE:** This option is set to the Vim default value when **'compatible'** is reset.

**'mzschemedll'** **'mzschemedll'**  
string (default depends on the build)  
global  
{only available when compiled with the **+mzscheme/dyn**  
feature}

Specifies the name of the MzScheme shared library. The default is DYNAMIC\_MZSCH\_DLL which was specified at compile time.

Environment variables are expanded **:set\_env** .

The value must be set in the **vimrc** script or earlier. In the startup, before the **load-plugins** step.

This option cannot be set from a **modeline** or in the **sandbox** , for security reasons.

**'mzschemegcdll'** **'mzschemegcdll'**  
string (default depends on the build)  
global  
{only available when compiled with the **+mzscheme/dyn**  
feature}

Specifies the name of the MzScheme GC shared library. The default is DYNAMIC\_MZGC\_DLL which was specified at compile time.

The value can be equal to **'mzschemedll'** if it includes the GC code.

Environment variables are expanded **:set\_env** .

This option cannot be set from a **modeline** or in the **sandbox** , for security reasons.

**'nrformats'** **'nf'** **'nrformats'** **'nf'**  
string (default "bin,octal,hex",  
set to "bin,hex" in **defaults.vim** )  
local to buffer

This defines what bases Vim will consider for numbers when using the **CTRL-A** and **CTRL-X** commands for adding to and subtracting from a number respectively; see **CTRL-A** for more info on these commands.

alpha If included, single alphabetical characters will be incremented or decremented. This is useful for a list with a letter index a), b), etc. **octal-nrformats**

octal If included, numbers that start with a zero will be considered to be octal. Example: Using **CTRL-A** on "007" results in "010".

hex If included, numbers starting with "0x" or "0X" will be considered to be hexadecimal. Example: Using **CTRL-X** on

"0x100" results in "0x0ff".

**bin** If included, numbers starting with "0b" or "0B" will be considered to be binary. Example: Using **CTRL-X** on "0b1000" subtracts one, resulting in "0b0111".

**unsigned** If included, numbers are recognized as unsigned. Thus a leading dash or negative sign won't be considered as part of the number. Examples:  
 Using **CTRL-X** on "2020" in "9-2020" results in "9-2019" (without "unsigned" it would become "9-2021").  
 Using **CTRL-A** on "2020" in "9-2020" results in "9-2021" (without "unsigned" it would become "9-2019").  
 Using **CTRL-X** on "0" or **CTRL-A** on "18446744073709551615" ( $2^{64} - 1$ ) has no effect, overflow is prevented.

**blank** If included, treat numbers as signed or unsigned based on preceding whitespace. If a number with a leading dash has its dash immediately preceded by a non-whitespace character (i.e., not a tab or a " "), the negative sign won't be considered as part of the number. For example:  
 Using **CTRL-A** on "14" in "Carbon-14" results in "Carbon-15" (without "blank" it would become "Carbon-13").  
 Using **CTRL-X** on "8" in "Carbon -8" results in "Carbon -9" (because -8 is preceded by whitespace. If "unsigned" was set, it would result in "Carbon -7").

If this format is included, overflow is prevented as if "unsigned" were set. If both this format and "unsigned" are included, "unsigned" will take precedence.

Numbers which simply begin with a digit in the range 1-9 are always considered decimal. This also happens for numbers that are not recognized as octal or hex.

**'number'** **'nu'** **'nonumber'** **'nonu'**  
 boolean (default off)  
 local to window

Print the line number in front of each line. When the 'n' option is excluded from **'coptions'** a wrapped line will not use the column of line numbers (this is the default when **'compatible'** isn't set). The **'numberwidth'** option can be used to set the room used for the line number.

When a long, wrapped line doesn't start with the first character, '-' characters are put before the number.

For highlighting see [hl-LineNr](#) , and [hl-CursorLineNr](#) , and the `:sign-define "numhl"` argument.

The **'relativenumber'** option changes the displayed number to be relative to the cursor. Together with **'number'** there are these four combinations (cursor in line 3):

	<b>'nonu'</b> <b>'nornu'</b>	<b>'nu'</b> <b>'nornu'</b>	<b>'nonu'</b> <b>'rnu'</b>	<b>'nu'</b> <b>'rnu'</b>
apple	1 apple	2 apple	2 apple	
pear	2 pear	1 pear	1 pear	
nobody	3 nobody	0 nobody	3 nobody	

|there | 4 there | 1 there | 1 there

**'numberwidth' 'nuw'** 'numberwidth' 'nuw'  
number (Vim default: 4 Vi default: 8)  
local to window  
{only available when compiled with the `+linebreak`  
feature}

Minimal number of columns to use for the line number. Only relevant when the `'number'` or `'relativenumber'` option is set or printing lines with a line number. Since one space is always between the number and the text, there is one less character for the number itself. The value is the minimum width. A bigger width is used when needed to fit the highest line number in the buffer respectively the number of rows in the window, depending on whether `'number'` or `'relativenumber'` is set. Thus with the Vim default of 4 there is room for a line number up to 999. When the buffer has 1000 lines five columns will be used. The minimum value is 1, the maximum value is 20.

**NOTE:** This option is set to the Vi default value when `'compatible'` is set and to the Vim default value when `'compatible'` is reset.

**'omnifunc' 'ofu'** 'omnifunc' 'ofu'  
string (default: empty)  
local to buffer  
{not available when compiled without the `+eval`  
feature}

This option specifies a function to be used for Insert mode omni completion with **CTRL-X CTRL-O**. `i_CTRL-X_CTRL-O`  
See [complete-functions](#) for an explanation of how the function is invoked and what it should return. The value can be the name of a function, a `lambda` or a `Funcref`. See [option-value-function](#) for more information.

This option is usually set by a filetype plugin:

```
:filetype-plugin-on
```

This option cannot be set from a `modeline` or in the `sandbox`, for security reasons.

**'opendev' 'odev'** 'opendev' 'odev' 'noopendev' 'noodev'  
boolean (default off)  
global  
{only for MS-Windows} [E796](#)

Enable reading and writing from devices. This may get Vim stuck on a device that can be opened but doesn't actually do the I/O. Therefore it is off by default.

**Note** that on MS-Windows editing `"aux.h"`, `"lpt1.txt"` and the like also result in editing a device.

**'operatorfunc' 'opfunc'** 'operatorfunc' 'opfunc'  
string (default: empty)  
global

This option specifies a function to be called by the `g@` operator. See [:map-operator](#) for more info and an example. The value can be the name of a function, a `lambda` or a `Funcref`. See [option-value-function](#) for more information.

This option cannot be set from a `modeline` or in the `sandbox`, for security reasons.

**'osfiletype' 'oft'** `string` (default: `""`)  
local to buffer

This option was supported on RISC OS, which has been removed.

**'packpath' 'pp'** `string` (default: see `'runtimepath'`)  
Directories used to find packages. See `packages`.

This option cannot be set from a `modeline` or in the `sandbox`, for security reasons.

**'paragraphs' 'para'** `string` (default `"IPLPPPQPP TPHPLIPpLpItpplpipbp"`)  
global

Specifies the nroff macros that separate paragraphs. These are pairs of two letters (see `object-motions`).

**'paste'** `boolean` (default off)  
global

Put Vim in Paste mode. This is useful if you want to cut or copy some text from one window and paste it in Vim. This will avoid unexpected effects.

Setting this option is useful when using Vim in a terminal, where Vim cannot distinguish between typed text and pasted text. In the GUI, Vim knows about pasting and will mostly do the right thing without `'paste'` being set. The same is true for a terminal where Vim handles the mouse clicks itself.

This option is reset when starting the GUI. Thus if you set it in your `.vimrc` it will work in a terminal, but not in the GUI. Setting `'paste'` in the GUI has side effects: e.g., the Paste toolbar button will no longer work in Insert mode, because it uses a mapping.

When the `'paste'` option is switched on (also when it was already on):

- mapping in Insert mode and Command-line mode is disabled
- abbreviations are disabled
- `'autoindent'` is reset
- `'expandtab'` is reset
- `'hkmap'` is reset
- `'revins'` is reset
- `'ruler'` is reset
- `'showmatch'` is reset
- `'smarttab'` is reset
- `'softtabstop'` is set to 0
- `'textwidth'` is set to 0
- `'wrapmargin'` is set to 0
- `'varsofttabstop'` is made empty

These options keep their value, but their effect is disabled:

- `'cindent'`
- `'formatoptions'` is used like it is empty
- `'indentexpr'`
- `'lisp'`

- **'smartindent'**

**NOTE:** When you start editing another file while the **'paste'** option is on, settings from the modelines or autocommands may change the settings again, causing trouble when pasting text. You might want to set the **'paste'** option again.

When the **'paste'** option is reset the mentioned options are restored to the value before the moment **'paste'** was switched from off to on.

Resetting **'paste'** before ever setting it does not have any effect.

Since mapping doesn't work while **'paste'** is active, you need to use the **'pastetoggle'** option to toggle the **'paste'** option with some key.

**'pastetoggle'** **'pt'** string (default "")  
global

When non-empty, specifies the key sequence that toggles the **'paste'** option. This is like specifying a mapping:

```
:map {keys} :set invpaste<CR>
```

Where {keys} is the value of **'pastetoggle'**.

The difference is that it will work even when **'paste'** is set.

**'pastetoggle'** works in Insert mode and Normal mode, but not in Command-line mode.

Mappings are checked first, thus overrule **'pastetoggle'**. However, when **'paste'** is on mappings are ignored in Insert mode, thus you can do this:

```
:map <F10> :set paste<CR>
:map <F11> :set nopaste<CR>
:imap <F10> <C-O>:set paste<CR>
:imap <F11> <nop>
:set pastetoggle=<F11>
```

This will make <F10> start paste mode and <F11> stop paste mode.

**Note** that typing <F10> in paste mode inserts "<F10>", since in paste mode everything is inserted literally, except the **'pastetoggle'** key sequence.

When the value has several bytes **'timeoutlen'** applies.

**'patchexpr'** **'pex'** string (default "")  
global  
{not available when compiled without the **+diff** feature}

Expression which is evaluated to apply a patch to a file and generate the resulting new version of the file. See [diff-patchexpr](#).

This option cannot be set from a [modeline](#) or in the [sandbox](#), for security reasons.

**'patchmode'** **'pm'** string (default "")  
global

When non-empty the oldest version of a file is kept. This can be used to keep the original version of a file if you are changing files in a source distribution. Only the first time that a file is written a copy of the original file will be kept. The name of the copy is the name of the original file with the string in the **'patchmode'** option appended. This option should start with a dot. Use a string like

".orig" or ".org". **'backupdir'** must not be empty for this to work (Detail: The backup file is renamed to the patchmode file after the new file has been successfully written, that's why it must be possible to write a backup file). If there was no file to be backed up, an empty file is created.

When the **'backupskip'** pattern matches, a patchmode file is not made. Using **'patchmode'** for compressed files appends the extension at the end (e.g., "file.gz.orig"), thus the resulting name isn't always recognized as a compressed file.

Only normal file name characters can be used, "/\\*?[]|<>" are illegal.

**'path'** **'pa'** string (default on Unix: "./usr/include,," other systems: ".,,")  
global or local to buffer **global-local**

This is a list of directories which will be searched when using the **gf**, **[f]**, **]f**, **^Wf**, **:find**, **:sfind**, **:tabfind** and other commands, provided that the file being searched for has a relative path (not starting with "/", "./" or "../"). The directories in the **'path'** option may be relative or absolute.

- Use commas to separate directory names:  
`:set path=./usr/local/include,/usr/include`
- Spaces can also be used to separate directory names (for backwards compatibility with version 3.0). To have a space in a directory name, precede it with an extra backslash, and escape the space:  
`:set path=./dir/with\\ space`
- To include a comma in a directory name precede it with an extra backslash:  
`:set path=./dir/with\\,comma`
- To search relative to the directory of the current file, use:  
`:set path=.`
- To search in the current directory use an empty string between two commas:  
`:set path=,,`
- A directory name may end in a ':' or '/'.
  - Environment variables are expanded `:set_env`.
  - When using **netrw.vim** URLs can be used. For example, adding `"http://www.vim.org"` will make `:find index.html` work.
  - Search upwards and downwards in a directory tree using `"*"`, `"**"` and `";"`. See **file-searching** for info and syntax.
  - Careful with `'\'` characters, type two to get one in the option:  
`:set path=.,c:\\include`  
Or just use `'/'` instead:  
`:set path=.,c:/include`

Don't forget "." or files won't even be found in the same directory as the file!

The maximum length is limited. How much depends on the system, mostly it is something like 256 or 1024 characters.

You can check if all the include files are found, using the value of **'path'**, see **:checkpath**.

The use of **:set+=** and **:set-=** is preferred when adding or removing directories from the list. This avoids problems when a future version uses another default. To remove the current directory use:

`:set path-=`

To add the current directory use:

```
:set path+=
```

To use an environment variable, you probably need to replace the separator. Here is an example to append \$INCL, in which directory names are separated with a semicolon:

```
:let &path = &path .. "," .. substitute($INCL, ';', ',', 'g')
```

Replace the ';' with a ':' or whatever separator is used. Note that this doesn't work when \$INCL contains a comma or white space.

```
'perldll' 'perldll'
string (default depends on the build)
global
{only available when compiled with the +perl/dyn
feature}
```

Specifies the name of the Perl shared library. The default is DYNAMIC\_PERL\_DLL, which was specified at compile time.

Environment variables are expanded `:set_env`.

This option cannot be set from a `modeline` or in the `sandbox`, for security reasons.

```
'preserveindent' 'pi' 'preserveindent' 'pi' 'nopreserveindent' 'nopi'
boolean (default off)
local to buffer
```

When changing the indent of the current line, preserve as much of the indent structure as possible. Normally the indent is replaced by a series of tabs followed by spaces as required (unless `'expandtab'` is enabled, in which case only spaces are used). Enabling this option means the indent will preserve as many existing characters as possible for indenting, and only add additional tabs or spaces as required.

`'expandtab'` does not apply to the preserved white space, a Tab remains a Tab.

**NOTE:** When using ">>" multiple times the resulting indent is a mix of tabs and spaces. You might not like this.

**NOTE:** This option is reset when `'compatible'` is set.

Also see `'copyindent'`.

Use `:retab` to clean up white space.

```
'previewheight' 'pvh' 'previewheight' 'pvh'
number (default 12)
global
{not available when compiled without the +quickfix
feature}
```

Default height for a preview window. Used for `:ptag` and associated commands. Used for `CTRL-W_}` when no count is given. Not used when `'previewpopup'` is set.

```
'previewpopup' 'pvp' 'previewpopup' 'pvp'
string (default empty)
global
{not available when compiled without the +textprop
or +quickfix feature}
```

When not empty a popup window is used for commands that would open a preview window. See `preview-popup`.

Not used for the insert completion info, add "popup" to

**'completeopt'** for that.

**'previewwindow'** **'pvw'** boolean (default off)  
local to window `local-noglobal`  
{not available when compiled without the `+quickfix` feature}  
Identifies the preview window. Only one window can have this option set. It's normally not set directly, but by using one of the commands `:ptag` , `:pedit` , etc.

**'printdevice'** **'pdev'** string (default empty)  
global  
{only available when compiled with the `+printer` feature}  
The name of the printer to be used for `:hardcopy` .  
See `pdev-option` .  
This option cannot be set from a `modeline` or in the `sandbox` , for security reasons.

**'printencoding'** **'penc'** string (default empty, except for some systems)  
global  
{only available when compiled with the `+printer` and `+postscript` features}  
Sets the character encoding used when printing.  
See `penc-option` .

**'printexpr'** **'pexpr'** string (default: see below)  
global  
{only available when compiled with the `+printer` and `+postscript` features}  
Expression used to print the PostScript produced with `:hardcopy` .  
See `pexpr-option` .  
This option cannot be set from a `modeline` or in the `sandbox` , for security reasons.

**'printfont'** **'pfn'** string (default "courier")  
global  
{only available when compiled with the `+printer` feature}  
The name of the font that will be used for `:hardcopy` .  
See `pfn-option` .

**'printhead'** **'pheader'** string (default "%<f%h%m%=Page %N")  
global  
{only available when compiled with the `+printer` feature}  
The format of the header produced in `:hardcopy` output.

See [pheader-option](#) .

**'printmbcharset'** **'pmbcs'** string (default "") 'printmbcharset' 'pmbcs'  
global  
{only available when compiled with the [+printer](#)  
and [+postscript](#) features}  
The CJK character set to be used for CJK output from [:hardcopy](#) .  
See [pmbcs-option](#) .

**'printmbfont'** **'pmbfn'** string (default "") 'printmbfont' 'pmbfn'  
global  
{only available when compiled with the [+printer](#)  
and [+postscript](#) features}  
List of font names to be used for CJK output from [:hardcopy](#) .  
See [pmbfn-option](#) .

**'printoptions'** **'popt'** string (default "") 'printoptions' 'popt'  
global  
{only available when compiled with [|+printer|](#) feature}  
List of items that control the format of the output of [:hardcopy](#) .  
See [popt-option](#) .

**'prompt'** boolean (default on) 'prompt' 'noprompt'  
global  
When on a ":" prompt is used in Ex mode.

**'pumheight'** **'ph'** number (default 0) 'pumheight' 'ph'  
global  
Determines the maximum number of items to show in the popup menu for  
Insert mode completion. When zero as much space as available is used.  
[ins-completion-menu](#) .

**'pumwidth'** **'pw'** number (default 15) 'pumwidth' 'pw'  
global  
Determines the minimum width to use for the popup menu for Insert mode  
completion. [ins-completion-menu](#) .

**'pythondll'** string (default depends on the build) 'pythondll'  
global  
{only available when compiled with the [+python/dyn](#)  
feature}  
Specifies the name of the Python 2.x shared library. The default is  
DYNAMIC\_PYTHON\_DLL, which was specified at compile time.  
Environment variables are expanded [:set\\_env](#) .  
This option cannot be set from a [modeline](#) or in the [sandbox](#) , for  
security reasons.

**'pythonhome'** 'pythonhome'

```
string (default "")
global
{only available when compiled with the +python/dyn
feature}
```

Specifies the name of the Python 2.x home directory. When **'pythonhome'** and the PYTHONHOME environment variable are not set, PYTHON\_HOME, which was specified at compile time, will be used for the Python 2.x home directory. Environment variables are expanded `:set_env` . This option cannot be set from a `modeline` or in the `sandbox` , for security reasons.

**'pythonthreadll'** 'pythonthreadll'

```
string (default depends on the build)
global
{only available when compiled with the +python3/dyn
feature}
```

Specifies the name of the Python 3 shared library. The default is DYNAMIC\_PYTHON3\_DLL, which was specified at compile time. Environment variables are expanded `:set_env` . This option cannot be set from a `modeline` or in the `sandbox` , for security reasons.

**'pythonthreehome'** 'pythonthreehome'

```
string (default "")
global
{only available when compiled with the +python3/dyn
feature}
```

Specifies the name of the Python 3 home directory. When **'pythonthreehome'** and the PYTHONHOME environment variable are not set, PYTHON3\_HOME, which was specified at compile time, will be used for the Python 3 home directory. Environment variables are expanded `:set_env` . This option cannot be set from a `modeline` or in the `sandbox` , for security reasons.

**'pyxversion'** **'pyx'** 'pyxversion' 'pyx'

```
number (default depends on the build)
global
{only available when compiled with the +python or
the +python3 feature}
```

Specifies the python version used for pyx\* functions and commands `python_x` . The default value is as follows:

Compiled with	Default
+python and +python3	0
only +python	2
only +python3	3

Available values are 0, 2 and 3. If **'pyxversion'** is 0, it is set to 2 or 3 after the first execution of any python2/3 commands or functions. E.g. `:py` sets to 2, and `:py3` sets to 3. `:pyx` sets it to 3 if Python 3 is available, otherwise sets

to 2 if Python 2 is available.  
See also: [has-pythonx](#)

If Vim is compiled with only [+python](#) or [+python3](#) setting **'pyxversion'** has no effect. The pyx\* functions and commands are always the same as the compiled version.

This option cannot be set from a [modeline](#) or in the [sandbox](#) , for security reasons.

**'quickfixtextfunc' 'qftf'** ['quickfixtextfunc'](#) ['qftf'](#)  
string (default "")  
global  
{only available when compiled with the [+quickfix](#) feature}

This option specifies a function to be used to get the text to display in the quickfix and location list windows. This can be used to customize the information displayed in the quickfix or location window for each entry in the corresponding quickfix or location list. See [quickfix-window-function](#) for an explanation of how to write the function and an example. The value can be the name of a function, a [lambda](#) or a [Funcref](#) . See [option-value-function](#) for more information.

This option cannot be set from a [modeline](#) or in the [sandbox](#) , for security reasons.

**'quotescape' 'qe'** ['quotescape'](#) ['qe'](#)  
string (default "\\")  
local to buffer

The characters that are used to escape quotes in a string. Used for objects like a', a" and a` a' .  
When one of the characters in this option is found inside a string, the following character will be skipped. The default value makes the text "foo\"bar\" considered to be one string.

**'readonly' 'ro'** ['readonly'](#) ['ro'](#) ['noreadonly'](#) ['noro'](#)  
boolean (default off)  
local to buffer [local-noglobal](#)

If on, writes fail unless you use a '!'. Protects you from accidentally overwriting a file. Default on when Vim is started in read-only mode ("vim -R") or when the executable is called "view". When using ":w!" the **'readonly'** option is reset for the current buffer, unless the 'Z' flag is in **'coptions'**.

When using the ":view" command the **'readonly'** option is set for the newly edited buffer.

See **'modifiable'** for disallowing changes to the buffer.

**'redrawtime' 'rdt'** ['redrawtime'](#) ['rdt'](#)  
number (default 2000)  
global  
{only available when compiled with the [+reltime](#) feature}

The time in milliseconds for redrawing the display. This applies to

searching for patterns for **'hlsearch'**, `:match` highlighting and syntax highlighting.

When redrawing takes more than this many milliseconds no further matches will be highlighted.

For syntax highlighting the time applies per window. When over the limit syntax highlighting is disabled until `CTRL-L` is used.

This is used to avoid that Vim hangs when using a very complicated pattern.

**'regexpengine'** **'re'**                    number (default 0)                    **'regexpengine'**    **'re'**  
                                          global

This selects the default regexp engine. `two-engines`

The possible values are:

- 0            automatic selection
- 1            old engine
- 2            NFA engine

**Note** that when using the NFA engine and the pattern contains something that is not supported the pattern will not match. This is only useful for debugging the regexp engine.

Using automatic selection enables Vim to switch the engine, if the default engine becomes too costly. E.g., when the NFA engine uses too many states. This should prevent Vim from hanging on a combination of a complex pattern with long text.

**'relativenumber'** **'rnu'**    **'norelativenumber'**    **'nornu'**  
**'relativenumber'** **'rnu'**    boolean (default off)  
                                          local to window

Show the line number relative to the line with the cursor in front of each line. Relative line numbers help you use the `count` you can precede some vertical motion commands (e.g. `j k + -`) with, without having to calculate it yourself. Especially useful in combination with other commands (e.g. `y d c < > gq gw =`).

When the 'n' option is excluded from **'coptions'** a wrapped line will not use the column of line numbers (this is the default when **'compatible'** isn't set).

The **'numberwidth'** option can be used to set the room used for the line number.

When a long, wrapped line doesn't start with the first character, '-' characters are put before the number.

See `hl-LineNr` and `hl-CursorLineNr` for the highlighting used for the number.

The number in front of the cursor line also depends on the value of **'number'**, see `number_relativenumber` for all combinations of the two options.

**'remap'**                                    **'remap'**    **'noremap'**  
                                          boolean (default on)  
                                          global

Allows for mappings to work recursively. If you do not want this for a single entry, use the `:noremap[!]` command.

**NOTE:** To avoid portability problems with Vim scripts, always keep this option at the default "on". Only switch it off when working with

old Vi scripts.

```
'renderoptions' 'rop' string (default: empty)
 global
 {only available when compiled with GUI and DIRECTX on
 MS-Windows}
```

Select a text renderer and set its options. The options depend on the renderer.

Syntax:

```
set rop=type:{renderer}({name}:{value})*
```

Currently, only one optional renderer is available.

### render behavior

directx Vim will draw text using DirectX (DirectWrite). It makes drawn glyphs more beautiful than default GDI.

It requires 'encoding' is "utf-8", and only works on MS-Windows Vista or newer version.

Options:

name	meaning	type	value
gamma	gamma	float	1.0 - 2.2 (maybe)
contrast	enhancedContrast	float	(unknown)
level	clearTypeLevel	float	(unknown)
geom	pixelGeometry	int	0 - 2 (see below)
renmode	renderingMode	int	0 - 6 (see below)
taamode	textAntialiasMode	int	0 - 3 (see below)
sctrlines	Scroll Lines	int	(deprecated)

See this URL for detail (except for sctrlines):

<https://msdn.microsoft.com/en-us/library/dd368190.aspx>

For geom: structure of a device pixel.

- 0 - DWRITE\_PIXEL\_GEOMETRY\_FLAT
- 1 - DWRITE\_PIXEL\_GEOMETRY\_RGB
- 2 - DWRITE\_PIXEL\_GEOMETRY\_BGR

See this URL for detail:

<https://msdn.microsoft.com/en-us/library/dd368114.aspx>

For renmode: method of rendering glyphs.

- 0 - DWRITE\_RENDERING\_MODE\_DEFAULT
- 1 - DWRITE\_RENDERING\_MODE\_ALIASED
- 2 - DWRITE\_RENDERING\_MODE\_GDI\_CLASSIC
- 3 - DWRITE\_RENDERING\_MODE\_GDI\_NATURAL
- 4 - DWRITE\_RENDERING\_MODE\_NATURAL
- 5 - DWRITE\_RENDERING\_MODE\_NATURAL\_SYMMETRIC
- 6 - DWRITE\_RENDERING\_MODE\_OUTLINE

See this URL for detail:

<https://msdn.microsoft.com/en-us/library/dd368118.aspx>

For taamode: antialiasing mode used for drawing text.

- 0 - D2D1\_TEXT\_ANTIALIAS\_MODE\_DEFAULT
- 1 - D2D1\_TEXT\_ANTIALIAS\_MODE\_CLEARTEXT
- 2 - D2D1\_TEXT\_ANTIALIAS\_MODE\_GRAYSCALE
- 3 - D2D1\_TEXT\_ANTIALIAS\_MODE\_ALIASED

See this URL for detail:

<https://msdn.microsoft.com/en-us/library/dd368170.aspx>

For scrips:

This was used for optimizing scrolling behavior, however this is now deprecated. If specified, it is simply ignored.

Example:

```
set encoding=utf-8
set gfn=Ricty_Diminished:h12
set rop=type:directx
```

If select a raster font (Courier, Terminal or FixedSys which have ".fon" extension in file name) to '**guifont**', it will be drawn by GDI as a fallback.

**NOTE:** It is known that some fonts and options combination causes trouble on drawing glyphs.

- 'renmode:5' and 'renmode:6' will not work with some special made fonts (True-Type fonts which includes only bitmap glyphs).
- 'taamode:3' will not work with some vector fonts.

**NOTE:** With this option, you can display colored emoji (emoticon) in Windows 8.1 or later. To display colored emoji, there are some conditions which you should notice.

- If your font includes non-colored emoji already, it will be used.
- If your font doesn't have emoji, the system chooses an alternative symbol font. On Windows 10, "Segoe UI Emoji" will be used.
- When this alternative font didn't have fixed width glyph, emoji might be rendered beyond the bounding box of drawing cell.

Other render types are currently not supported.

**'report'**

number (default 2)  
global

**'report'**

Threshold for reporting number of lines changed. When the number of changed lines is more than '**report**' a message will be given for most ":" commands. If you want it always, set '**report**' to 0. For the ":substitute" command the number of substitutions is used instead of the number of lines.

**'restorescreen' 'rs'** **'restorescreen'** **'rs'** **'norestorescreen'** **'nors'**  
boolean (default on)  
global  
{only in MS-Windows console version}

When set, the screen contents is restored when exiting Vim. This also happens when executing external commands.

For non-Windows Vim: You can set or reset the **'t\_ti'** and **'t\_te'** options in your .vimrc. To disable restoring:

```
set t_ti= t_te=
```

To enable restoring (for an xterm):

```
set t_ti=^[7^[[r^[[?47h t_te=^[[?47l^[8
```

(Where **^[** is an **<Esc>**, type **CTRL-V <Esc>** to insert it)

**'revins' 'ri'** **'revins'** **'ri'** **'norevins'** **'nori'**  
boolean (default off)  
global  
{only available when compiled with the **+rightleft** feature}

Inserting characters in Insert mode will work backwards. See "typing backwards" **ins-reverse** . This option can be toggled with the **CTRL-\_** command in Insert mode, when **'allowrevins'** is set.

**NOTE:** This option is reset when **'compatible'** is set.

This option is reset when **'paste'** is set and restored when **'paste'** is reset.

**'rightleft' 'rl'** **'rightleft'** **'rl'** **'norightleft'** **'norl'**  
boolean (default off)  
local to window  
{only available when compiled with the **+rightleft** feature}

When on, display orientation becomes right-to-left, i.e., characters that are stored in the file appear from the right to the left.

Using this option, it is possible to edit files for languages that are written from the right to the left such as Hebrew and Arabic. This option is per window, so it is possible to edit mixed files simultaneously, or to view the same file in both ways (this is useful whenever you have a mixed text file with both right-to-left and left-to-right strings so that both sets are displayed properly in different windows). Also see **rileft.txt** .

**'rightleftcmd' 'rlc'** **'rightleftcmd'** **'rlc'**  
string (default "search")  
local to window  
{only available when compiled with the **+rightleft** feature}

Each word in this option enables the command line editing to work in right-to-left mode for a group of commands:

```
search "/" and "?" commands
```

This is useful for languages such as Hebrew, Arabic and Farsi.

The **'rightleft'** option must be set for **'rightleftcmd'** to take effect.

**'rubydll'** 'rubydll'  
 string (default: depends on the build)  
 global  
 {only available when compiled with the `+ruby/dyn`  
 feature}

Specifies the name of the Ruby shared library. The default is DYNAMIC\_RUBY\_DLL, which was specified at compile time. Environment variables are expanded `:set_env`. This option cannot be set from a `modeline` or in the `sandbox`, for security reasons.

**'ruler' 'ru'** 'ruler' 'ru' 'noruler' 'noru'  
 boolean (default off, set in `defaults.vim`)  
 global

Show the line and column number of the cursor position, separated by a comma. When there is room, the relative position of the displayed text in the file is shown on the far right:

```

Top first line is visible
Bot last line is visible
All first and last line are visible
45% relative position in the file

```

If **'rulerformat'** is set, it will determine the contents of the ruler. Each window has its own ruler. If a window has a status line, the ruler is shown there. Otherwise it is shown in the last line of the screen. If the statusline is given by **'statusline'** (i.e. not empty), this option takes precedence over **'ruler'** and **'rulerformat'**.

If the number of characters displayed is different from the number of bytes in the text (e.g., for a TAB or a multibyte character), both the text column (byte number) and the screen column are shown, separated with a dash.

For an empty line "0-1" is shown.

For an empty buffer the line number will also be zero: "0,0-1".

This option is reset when **'paste'** is set and restored when **'paste'** is reset.

If you don't want to see the ruler all the time but want to know where you are, use `"g CTRL-G" g_CTRL-G`.

**NOTE:** This option is reset when **'compatible'** is set.

**'rulerformat' 'ruf'** 'rulerformat' 'ruf'  
 string (default empty)  
 global  
 {not available when compiled without the `+statusline`  
 feature}

When this option is not empty, it determines the content of the ruler string, as displayed for the **'ruler'** option.

The format of this option is like that of **'statusline'**.

This option cannot be set in a `modeline` when **'modelineexpr'** is off.

The default ruler width is 17 characters. To make the ruler 15 characters wide, put "%15(" at the start and "%)" at the end.

Example:

```
:set rulerformat=%15(%c%\ %p%%%)
```

**'runtimepath' 'rtp' vimfiles**

```

'runtimepath' 'rtp' string (default:
 Unix: "$HOME/.vim or
 $XDG_CONFIG_HOME/vim,
 $VIM/vimfiles,
 $VIMRUNTIME,
 $VIM/vimfiles/after,
 $HOME/.vim/after"
 Amiga: "home:vimfiles,
 $VIM/vimfiles,
 $VIMRUNTIME,
 $VIM/vimfiles/after,
 home:vimfiles/after"
 MS-Windows: "$HOME/vimfiles,
 $VIM/vimfiles,
 $VIMRUNTIME,
 $VIM/vimfiles/after,
 $HOME/vimfiles/after"
 Haiku: "$BE_USER_SETTINGS/vim,
 $VIM/vimfiles,
 $VIMRUNTIME,
 $VIM/vimfiles/after,
 $BE_USER_SETTINGS/vim/after"
 VMS: "sys$login:vimfiles,
 $VIM/vimfiles,
 $VIMRUNTIME,
 $VIM/vimfiles/after,
 sys$login:vimfiles/after")
 global

```

This is a list of directories which will be searched for runtime files:

filetype.vim	filetypes by file name	<a href="#">new-filetype</a>
scripts.vim	filetypes by file contents	<a href="#">new-filetype-scripts</a>
autoload/	automatically loaded scripts	<a href="#">autoload-functions</a>
colors/	color scheme files	<a href="#">:colorscheme</a>
compiler/	compiler files	<a href="#">:compiler</a>
doc/	documentation	<a href="#">write-local-help</a>
ftplugin/	filetype plugins	<a href="#">write-filetype-plugin</a>
import/	files that are found by <code>`:import`</code>	
indent/	indent scripts	<a href="#">indent-expression</a>
keymap/	key mapping files	<a href="#">mbyte-keymap</a>
lang/	message translations	<a href="#">:menutrans</a> and <a href="#">multi-lang</a>
menu.vim	GUI menus	<a href="#">menu.vim</a>
pack/	packages	<a href="#">:packadd</a>
plugin/	plugin scripts	<a href="#">write-plugin</a>
print/	files for printing	<a href="#">postscript-print-encoding</a>
spell/	spell checking files	<a href="#">spell</a>
syntax/	syntax files	<a href="#">mysyntaxfile</a>
tutor/	files for vimtutor	<a href="#">tutor</a>

And any other file searched for with the `:runtime` command.

For `$XDG_CONFIG_HOME` see [xdg-base-dir](#) .

The defaults for most systems are setup to search five locations:

1. In your home directory, for your personal preferences.
2. In a system-wide Vim directory, for preferences from the system administrator.
3. In \$VIMRUNTIME, for files distributed with Vim.
4. In the "after" directory in the system-wide Vim directory. This is for the system administrator to overrule or add to the distributed defaults (rarely needed)
5. In the "after" directory in your home directory. This is for personal preferences to overrule or add to the distributed defaults or system-wide settings (rarely needed).

More entries are added when using `packages` . If it gets very long then `:set rtp`` will be truncated, use `:echo &rtp`` to see the full string.

**Note** that, unlike `'path'`, no wildcards like `"**"` are allowed. Normal wildcards are allowed, but can significantly slow down searching for runtime files. For speed, use as few items as possible and avoid wildcards.

See `:runtime` .

Example:

```
:set runtimepath=~/.vimruntime,/mygroup/vim,$VIMRUNTIME
```

This will use the directory `"~/.vimruntime"` first (containing your personal Vim runtime files), then `"/mygroup/vim"` (shared between a group of people) and finally `"$VIMRUNTIME"` (the distributed runtime files).

You probably should always include `$VIMRUNTIME` somewhere, to use the distributed runtime files. You can put a directory before `$VIMRUNTIME` to find files which replace a distributed runtime files. You can put a directory after `$VIMRUNTIME` to find files which add to distributed runtime files.

When Vim is started with `--clean` the home directory entries are not included.

This option cannot be set from a `modeline` or in the `sandbox` , for security reasons.

```

'scroll' 'scr' number (default: half the window height)
 local to window local-noglobal
Number of lines to scroll with CTRL-U and CTRL-D commands. Will be
set to half the number of lines in the window when the window size
changes. This may happen when enabling the status-line or
'tabline' option after setting the 'scroll' option.
If you give a count to the CTRL-U or CTRL-D command it will
be used as the new value for 'scroll'. Reset to half the window
height with ":set scroll=0".

```

```

'scrollbind' 'scb' 'scrollbind' 'scb' 'noscrollbind' 'noscb'
boolean (default off)
local to window
See also scroll-binding . When this option is set, scrolling the
current window also scrolls other scrollbind windows (windows that
also have this option set). This option is useful for viewing the

```

differences between two versions of a file, see **'diff'**.  
See **'scrollopt'** for options that determine how this option should be interpreted.  
This option is mostly reset when splitting a window to edit another file. This means that `:split | edit file` results in two windows with scroll-binding, but `:split file` does not.

**'scrollfocus' 'scf'**                    **'scrollfocus' 'scf'**    **'noscrollfocus' 'noscf'**  
boolean (default off)  
global  
{only for MS-Windows GUI}

When using the scroll wheel and this option is set, the window under the mouse pointer is scrolled. With this option off the current window is scrolled.  
Systems other than MS-Windows always behave like this option is on.

**'scrolljump' 'sj'**                    **'scrolljump' 'sj'**  
number (default 1)  
global

Minimal number of lines to scroll when the cursor gets off the screen (e.g., with "j"). Not used for scroll commands (e.g., **CTRL-E**, **CTRL-D**). Useful if your terminal scrolls very slowly.  
When set to a negative number from -1 to -100 this is used as the percentage of the window height. Thus -50 scrolls half the window height.  
**NOTE:** This option is set to 1 when **'compatible'** is set.

**'scrolloff' 'so'**                    **'scrolloff' 'so'**  
number (default 0, set to 5 in `defaults.vim`)  
global or local to window `global-local`

Minimal number of screen lines to keep above and below the cursor. This will make some context visible around where you are working. If you set it to a very large value (999) the cursor line will always be in the middle of the window (except at the start or end of the file or when long lines wrap).  
After using the local value, go back the global value with one of these two:

```
setlocal scrolloff<
setlocal scrolloff=-1
```

For scrolling horizontally see **'sidescrolloff'**.

**NOTE:** This option is set to 0 when **'compatible'** is set.

**'scrollopt' 'sbo'**                    **'scrollopt' 'sbo'**  
string (default "ver,jump")  
global

This is a comma-separated list of words that specifies how **'scrollbind'** windows should behave. **'sbo'** stands for ScrollBind Options.

The following words are available:

ver	Bind vertical scrolling for <b>'scrollbind'</b> windows
hor	Bind horizontal scrolling for <b>'scrollbind'</b> windows
jump	Applies to the offset between two windows for vertical scrolling. This offset is the difference in the first displayed line of the bound windows. When moving

around in a window, another **'scrollbind'** window may reach a position before the start or after the end of the buffer. The offset is not changed though, when moving back the **'scrollbind'** window will try to scroll to the desired position when possible.

When now making that window the current one, two things can be done with the relative offset:

1. When "jump" is not included, the relative offset is adjusted for the scroll position in the new current window. When going back to the other window, the new relative offset will be used.
2. When "jump" is included, the other windows are scrolled to keep the same relative offset. When going back to the other window, it still uses the same relative offset.

Also see [scroll-binding](#) .

When **'diff'** mode is active there always is vertical scroll binding, even when "ver" isn't there.

**'sections'** **'sect'** **'sections'** **'sect'**  
string (default "SHNHH HUUnhsh")  
global

Specifies the nroff macros that separate sections. These are pairs of two letters (See [object-motions](#) ). The default makes a section start at the nroff macros ".SH", ".NH", ".H", ".HU", ".nh" and ".sh".

**'secure'** **'secure'** **'nosecure'** E523  
boolean (default off)  
global

When on, ":autocmd", shell and write commands are not allowed in ".vimrc" and ".exrc" in the current directory and map commands are displayed. Switch it off only if you know that you will not run into problems, or when the **'exrc'** option is off. On Unix this option is only used if the ".vimrc" or ".exrc" is not owned by you. This can be dangerous if the systems allows users to do a "chown". You better set **'secure'** at the end of your ~/.vimrc then.

This option cannot be set from a [modeline](#) or in the [sandbox](#) , for security reasons.

**'selection'** **'sel'** **'selection'** **'sel'**  
string (default "inclusive")  
global

This option defines the behavior of the selection. It is only used in Visual and Select mode.

Possible values:

value	past line	inclusive
old	no	yes
inclusive	yes	yes
exclusive	yes	no

"past line" means that the cursor is allowed to be positioned one character past the line.

"inclusive" means that the last character of the selection is included in an operation. For example, when "x" is used to delete the selection.

When "old" is used and **'virtualedit'** allows the cursor to move past the end of line the line break still isn't included.  
 When "exclusive" is used, cursor position in visual mode will be adjusted for inclusive motions [inclusive-motion-selection-exclusive](#) .  
**Note** that when "exclusive" is used and selecting from the end backwards, you cannot include the last character of a line, when starting in Normal mode and **'virtualedit'** empty.

The **'selection'** option is set by the `:behave` command.

**'selectmode'** **'slm'** string (default "")  
**'selectmode'** **'slm'**  
 global

This is a comma-separated list of words, which specifies when to start Select mode instead of Visual mode, when a selection is started.

Possible values:

mouse	when using the mouse
key	when using shifted special keys
cmd	when using "v", "V" or <b>CTRL-V</b>

See [Select-mode](#) .

The **'selectmode'** option is set by the `:behave` command.

**'sessionoptions'** **'ssop'** string (default: "blank,buffers,curdir,folds,  
**'sessionoptions'** **'ssop'**  
 help,options,tabpages,winsize,terminal")  
 global  
 {not available when compiled without the `+mksession`  
 feature}

Changes the effect of the `:mksession` command. It is a comma separated list of words. Each word enables saving and restoring something:

<b>word</b>	<b>save and restore</b>
blank	empty windows
buffers	hidden and unloaded buffers, not just those in windows
curdir	the current directory
folders	manually created folds, opened/closed folds and local fold options
globals	global variables that start with an uppercase letter and contain at least one lowercase letter. Only String and Number types are stored.
help	the help window
localoptions	options and mappings local to a window or buffer (not global values for local options)
options	all options and mappings (also global values for local options)
skiprtp	exclude <b>'runtimepath'</b> and <b>'packpath'</b> from the options
resize	size of the Vim window: <b>'lines'</b> and <b>'columns'</b>
sesdir	the directory in which the session file is located will become the current directory (useful with projects accessed over a network from different systems)
slash	backslashes in file names replaced with forward slashes
tabpages	all tab pages; without this only the current tab page

	is restored, so that you can make a session for each tab page separately
terminal	include terminal windows where the command can be restored
unix	with Unix end-of-line format (single <code>&lt;NL&gt;</code> ), even when on Windows or DOS
winpos	position of the whole Vim window
winsize	window sizes

Don't include both "curdir" and "sesdir".

When neither "curdir" nor "sesdir" is included, file names are stored with absolute paths.

If you leave out "options" many things won't work well after restoring the session.

"slash" and "unix" are useful on Windows when sharing session files with Unix. The Unix version of Vim cannot source dos format scripts, but the Windows version of Vim can source unix format scripts.

**'shell' 'sh'** string (default \$SHELL or "sh", Win32: "cmd.exe")  
 global

Name of the shell to use for ! and :! commands. When changing the value also check these options: **'shelltype'**, **'shellpipe'**, **'shellslash'**, **'shellredir'**, **'shellquote'**, **'shellxquote'** and **'shellcmdflag'**.

It is allowed to give an argument to the command, e.g. "csh -f".

See [option-backslash](#) about including spaces and backslashes.

Environment variables are expanded `:set_env` .

In [restricted-mode](#) shell commands will not be possible. This mode is used if the value of \$SHELL ends in "false" or "nologin".

If the name of the shell contains a space, you need to enclose it in quotes and escape the space. Example with quotes:

```
:set shell=\"c:\program\ files\unix\sh.exe\" -f
```

**Note** the backslash before each quote (to avoid starting a comment) and each space (to avoid ending the option value). Also **note** that the "-f" is not inside the quotes, because it is not part of the command name. Vim automatically recognizes the backslashes that are path separators.

Example with escaped space (Vim will do this when initializing the option from \$SHELL):

```
:set shell=/bin/with\\ space/sh
```

The resulting value of **'shell'** is "/bin/with\ space/sh", two backslashes are consumed by `:set``.

Under MS-Windows, when the executable ends in ".com" it must be included. Thus setting the shell to "command.com" or "4dos.com" works, but "command" and "4dos" do not work for all commands (e.g., filtering).

For unknown reasons, when using "4dos.com" the current directory is changed to "C:\". To avoid this set **'shell'** like this:

```
:set shell=command.com\ /c\ 4dos
```

This option cannot be set from a [modeline](#) or in the [sandbox](#) , for security reasons.

**'shellcmdflag' 'shcf'** string (default: "-c";  
 Win32, when **'shell'** contains "powershell":  
 "-Command", or when it does not contain "sh"  
 somewhere: "/c")

global

Flag passed to the shell to execute "!" and "!!" commands; e.g.,  
 "bash.exe -c ls", "powershell.exe -Command dir", or "cmd.exe /c dir".  
 For MS-Windows, the default is set according to the value of **'shell'**,  
 to reduce the need to set this option by the user.

On Unix it can have more than one flag. Each white space separated  
 part is passed as an argument to the shell command.

See [option-backslash](#) about including spaces and backslashes.

Also see [dos-shell](#) and [dos-powershell](#) for MS-Windows.

This option cannot be set from a [modeline](#) or in the [sandbox](#) , for  
 security reasons.

**'shellpipe' 'sp'** string (default ">", ">%s 2>&1", "| tee", "|& tee"  
 "2>&1| tee", or  
 "2>&1 | Out-File -Encoding default")

global

{not available when compiled without the [+quickfix](#)  
 feature}

String to be used to put the output of the ":make" command in the  
 error file. See also [:make\\_makeprg](#) . See [option-backslash](#) about  
 including spaces and backslashes.

The name of the temporary file can be represented by "%s" if necessary  
 (the file name is appended automatically if no %s appears in the value  
 of this option).

For the Amiga the default is ">". For MS-Windows using powershell the  
 default is "2>&1 | Out-File -Encoding default", otherwise the default  
 is ">%s 2>&1". The output is directly saved in a file and not echoed  
 to the screen.

For Unix the default is "| tee". The stdout of the compiler is saved  
 in a file and echoed to the screen. If the **'shell'** option is "csh" or  
 "tcsh" after initializations, the default becomes "|& tee". If the  
**'shell'** option is "sh", "ksh", "mksh", "pdksh", "zsh", "zsh-beta",  
 "bash", "fish", "ash" or "dash" the default becomes "2>&1| tee". This  
 means that stderr is also included. Before using the **'shell'** option a  
 path is removed, thus "/bin/sh" uses "sh".

For Unix and MS-Windows, when the **'shell'** option is "pwsh" the default  
 becomes ">%s 2>&1" and the output is not echoed to the screen.

The initialization of this option is done after reading the ".vimrc"  
 and the other initializations, so that when the **'shell'** option is set  
 there, the **'shellpipe'** option changes automatically, unless it was  
 explicitly set before.

When **'shellpipe'** is set to an empty string, no redirection of the  
 ":make" output will be done. This is useful if you use a **'makeprg'**  
 that writes to **'makeef'** by itself. If you want no piping, but do  
 want to include the **'makeef'**, set **'shellpipe'** to a single space.

Don't forget to precede the space with a backslash: ":set sp=\ ".

In the future pipes may be used for filtering and this option will

become obsolete (at least for Unix).

This option cannot be set from a [modeline](#) or in the [sandbox](#) , for security reasons.

**'shellquote' 'shq'** **'shellquote' 'shq'**  
string (default: "")  
global  
Quoting character(s), put around the command passed to the shell, for the "!" and "!!" commands. The redirection is kept outside of the quoting. See **'shellxquote'** to include the redirection. It's probably not useful to set both options.  
This is an empty string by default. Only known to be useful for third-party shells on MS-Windows-like systems, such as the MKS Korn Shell or bash, where it should be "\". See [dos-shell](#) .  
This option cannot be set from a [modeline](#) or in the [sandbox](#) , for security reasons.

**'shellredir' 'srr'** **'shellredir' 'srr'**  
string (default ">", ">&", ">%s 2>&1", or  
"2>&1 | Out-File -Encoding default")  
global  
String to be used to put the output of a filter command in a temporary file. See also [:!](#) . See [option-backslash](#) about including spaces and backslashes.  
The name of the temporary file can be represented by "%s" if necessary (the file name is appended automatically if no %s appears in the value of this option).  
The default is ">". For Unix, if the **'shell'** option is "csh" or "tcsh" during initializations, the default becomes ">&". If the **'shell'** option is "sh", "ksh", "mksh", "pdksh", "zsh", "zsh-beta", "bash", "fish", or "pwsh", the default becomes ">%s 2>&1". This means that stderr is also included. For Win32, the Unix checks are done and additionally "cmd" is checked for, which makes the default ">%s 2>&1", and "powershell" is checked for which makes the default "2>&1 | Out-File -Encoding default" (see [dos-powershell](#) ). Also, the same names with ".exe" appended are checked for.  
The initialization of this option is done after reading the ".vimrc" and the other initializations, so that when the **'shell'** option is set there, the **'shellredir'** option changes automatically unless it was explicitly set before.  
In the future pipes may be used for filtering and this option will become obsolete (at least for Unix).  
This option cannot be set from a [modeline](#) or in the [sandbox](#) , for security reasons.

**'shellslash' 'ssl'** **'shellslash' 'ssl' 'noshellslash' 'nossl'**  
boolean (default off)  
global  
{only for MS-Windows}  
When set, a forward slash is used when expanding file names. This is useful when a Unix-like shell is used instead of cmd.exe, pwsh.exe, or powershell.exe. Backward slashes can still be typed, but they are changed to forward slashes by Vim.  
**Note** that setting or resetting this option has no effect for some

existing file names, thus this option needs to be set before opening any file for best results. This might change in the future.

'shellslash' only works when a backslash can be used as a path separator. To test if this is so use:

```
if exists('+shellslash')
```

Also see 'completeslash'.

```
'shelltemp' 'stmp' 'shelltemp' 'stmp' 'noshelltemp' 'nostmp'
boolean (Vi default off, Vim default on)
global
```

When on, use temp files for shell commands. When off use a pipe. When using a pipe is not possible temp files are used anyway.

Currently a pipe is only supported on Unix and MS-Windows 2K and later. You can check it with:

```
:if has("filterpipe")
```

The advantage of using a pipe is that nobody can read the temp file and the 'shell' command does not need to support redirection.

The advantage of using a temp file is that the file type and encoding can be detected.

The FilterReadPre , FilterReadPost and FilterWritePre , FilterWritePost autocommands event are not triggered when 'shelltemp' is off.

The `system()` function does not respect this option and always uses temp files.

NOTE: This option is set to the Vim default value when 'compatible' is reset.

```
'shelltype' 'st' 'shelltype' 'st'
number (default 0)
global
{only for the Amiga}
```

On the Amiga this option influences the way how the commands work which use a shell.

0 and 1: always use the shell

2 and 3: use the shell only to filter lines

4 and 5: use shell only for ':sh' command

When not using the shell, the command is executed directly.

0 and 2: use "shell 'shellcmdflag' cmd" to start external commands

1 and 3: use "shell cmd" to start external commands

```
'shellxescape' 'sxe' 'shellxescape' 'sxe'
string (default: "");
for MS-Windows: "\"&|<>()@^")
global
```

When 'shellxquote' is set to "(" then the characters listed in this option will be escaped with a '^' character. This makes it possible to execute most external commands with cmd.exe.

This option cannot be set from a modeline or in the sandbox , for security reasons.

```
'shellxquote' 'sxq' 'shellxquote' 'sxq'
string (default: "");
for Win32, when 'shell' is cmd.exe: "("
```

for Win32, when **'shell'** is powershell.exe: "\"  
 for Win32, when **'shell'** contains "sh" somewhere: "\"  
 for Unix, when using system(): "\"

global

Quoting character(s), put around the command passed to the shell, for the "!" and ":!" commands. Includes the redirection. See **'shellquote'** to exclude the redirection. It's probably not useful to set both options.

When the value is '(' then ')' is appended. When the value is '(' then ')"' is appended.

When the value is '(' then also see **'shellxescape'**.

This is an empty string by default on most systems, but is known to be useful for on Win32 version, either for cmd.exe, powershell.exe, or pwsh.exe which automatically strips off the first and last quote on a command, or 3rd-party shells such as the MKS Korn Shell or bash, where it should be "\". The default is adjusted according the value of **'shell'**, to reduce the need to set this option by the user. See **dos-shell**.

This option cannot be set from a **modeline** or in the **sandbox**, for security reasons.

**'shiftround'** **'sr'** **'shiftround'** **'sr'** **'noshiftround'** **'nosr'**  
 boolean (default off)  
 global

Round indent to multiple of **'shiftwidth'**. Applies to > and < commands. **CTRL-T** and **CTRL-D** in Insert mode always round the indent to a multiple of **'shiftwidth'** (this is Vi compatible).

**NOTE:** This option is reset when **'compatible'** is set.

**'shiftwidth'** **'sw'** **'shiftwidth'** **'sw'**  
 number (default 8)  
 local to buffer

Number of spaces to use for each step of (auto)indent. Used for **'cindent'**, >>, <<, etc.

When zero the **'tabstop'** value will be used. Use the **shiftwidth()** function to get the effective shiftwidth value.

**'shortmess'** **'shm'** **'shortmess'** **'shm'**  
 string (Vim default "filnxtToOS", Vi default: "S",  
 POSIX default: "AS")  
 global **E1336**

This option helps to avoid all the **hit-enter** prompts caused by file messages, for example with **CTRL-G**, and to avoid some other messages. It is a list of flags:

flag	meaning when present	
f	use "(3 of 5)" instead of "(file 3 of 5)"	shm-f
i	use "[noeol]" instead of "[Incomplete last line]"	shm-i
l	use "999L, 888B" instead of "999 lines, 888 bytes"	shm-l
m	use "[+]" instead of "[Modified]"	shm-m
n	use "[New]" instead of "[New File]"	shm-n
r	use "[RO]" instead of "[readonly]"	shm-r
w	use "[w]" instead of "written" for file write message	shm-w

x	and "[a]" instead of "appended" for ':w >> file' command use "[dos]" instead of "[dos format]", "[unix]" instead of "[unix format]" and "[mac]" instead of "[mac format]"	shm-x
a	all of the above abbreviations	shm-a
o	overwrite message for writing a file with subsequent message for reading a file (useful for ":wn" or when <b>'autowrite'</b> on)	shm-o
O	message for reading a file overwrites any previous message; also for quickfix message (e.g., ":cn")	shm-O
s	don't give "search hit BOTTOM, continuing at TOP" or "search hit TOP, continuing at BOTTOM" messages; when using the search count do not show "W" before the count message (see <a href="#">shm-S</a> below)	shm-s
t	truncate file message at the start if it is too long to fit on the command-line, "<" will appear in the left most column; ignored in Ex mode	shm-t
T	truncate other messages in the middle if they are too long to fit on the command line; "... " will appear in the middle; ignored in Ex mode	shm-T
W	don't give "written" or "[w]" when writing a file	shm-W
A	don't give the "ATTENTION" message when an existing swap file is found	shm-A
I	don't give the intro message when starting Vim, see <a href="#">:intro</a>	shm-I
c	don't give <a href="#">ins-completion-menu</a> messages; for example, "-- XXX completion (YYY)", "match 1 of 2", "The only match", "Pattern not found", "Back at original", etc.	shm-c
C	don't give messages while scanning for ins-completion items, for instance "scanning tags"	shm-C
q	use "recording" instead of "recording @a"	shm-q
F	don't give the file info when editing a file, like <a href="#">`:silent`</a> was used for the command; <a href="#">note</a> that this also affects messages from autocommands and <b>'autoread'</b> reloading	shm-F
S	do not show search count message when searching, e.g. "[1/5]". When the "S" flag is not present (e.g. search count is shown), the "search hit BOTTOM, continuing at TOP" and "search hit TOP, continuing at BOTTOM" messages are only indicated by a "W" (Mnemonic: Wrapped) letter before the search count statistics.	shm-S

This gives you the opportunity to avoid that a change between buffers requires you to hit [<Enter>](#), but still gives as useful a message as possible for the space available. To get the whole message that you would have got with **'shm'** empty, use ":file!"

Useful values:

shm=	No abbreviation of message.
shm=a	Abbreviation, but no loss of information.
shm=at	Abbreviation, and truncate message when necessary.

**NOTE:** This option is set to the Vi default value when **'compatible'** is set and to the Vim default value when **'compatible'** is reset.

**'shortname' 'sn'** 'shortname' 'sn' 'noshortname' 'nosn'  
 boolean (default off)  
 local to buffer

Filenames are assumed to be 8 characters plus one extension of 3 characters. Multiple dots in file names are not allowed. When this option is on, dots in file names are replaced with underscores when adding an extension (".~" or ".swp"). This option is useful when editing files on an MS-DOS compatible filesystem, e.g., messydos or crossdos.

**'showbreak' 'sbr'** 'showbreak' 'sbr' E595  
 string (default "")  
 global or local to window global-local  
 {not available when compiled without the +linebreak feature}

String to put at the start of lines that have been wrapped. Useful values are "> " or "+++ ":

```
:set showbreak=>\
```

**Note** the backslash to escape the trailing space. It's easier like this:

```
:let &showbreak = '+++ '
```

Only printable single-cell characters are allowed, excluding <Tab> and comma (in a future version the comma might be used to separate the part that is shown at the end and at the start of a line).

The characters are highlighted according to the '@' flag in **'highlight'**.

**Note** that tabs after the showbreak will be displayed differently.

If you want the **'showbreak'** to appear in between line numbers, add the "n" flag to **'coptions'**.

A window-local value overrules a global value. If the global value is set and you want no value in the current window use NONE:

```
:setlocal showbreak=NONE
```

**'showcmd' 'sc'** 'showcmd' 'sc' 'noshowcmd' 'nosc'  
 boolean (Vim default: on, off for Unix,  
 Vi default: off, set in defaults.vim)  
 global

Show (partial) command in the last line of the screen. Set this option off if your terminal is slow.

In Visual mode the size of the selected area is shown:

- When selecting characters within a line, the number of characters.  
 If the number of bytes is different it is also displayed: "2-6" means two characters and six bytes.
- When selecting more than one line, the number of lines.
- When selecting a block, the size in screen characters:  
{lines}x{columns}.

This information can be displayed in an alternative location using the **'showcmdloc'** option.

**NOTE:** This option is set to the Vi default value when **'compatible'** is set and to the Vim default value when **'compatible'** is reset.

**'showcmdloc' 'sloc'** 'showcmdloc' 'sloc'  
 string (default "last")  
 global

This option can be used to display the (partially) entered command in another location. Possible values are:

last Last line of the screen (default).  
statusline Status line of the current window.  
tabline First line of the screen if **'showtabline'** is enabled.

Setting this option to "statusline" or "tabline" means that these will be redrawn whenever the command changes, which can be on every key pressed.

The %S **'statusline'** item can be used in **'statusline'** or **'tabline'** to place the text. Without a custom **'statusline'** or **'tabline'** it will be displayed in a convenient location.

**'showfulltag' 'sft'** **'showfulltag' 'sft' 'nshowfulltag' 'nosft'**  
boolean (default off)  
global

When completing a word in insert mode (see [ins-completion](#)) from the tags file, show both the tag name and a tidied-up form of the search pattern (if there is one) as possible matches. Thus, if you have matched a C function, you can see a template for what arguments are required (coding style permitting).

**Note** that this doesn't work well together with having "longest" in **'completeopt'**, because the completion from the search pattern may not match the typed text.

**'showmatch' 'sm'** **'showmatch' 'sm' 'nshowmatch' 'nosm'**  
boolean (default off)  
global

When a bracket is inserted, briefly jump to the matching one. The jump is only done if the match can be seen on the screen. The time to show the match can be set with **'matchtime'**.

A Beep is given if there is no match (no matter if the match can be seen or not).

This option is reset when **'paste'** is set and restored when **'paste'** is reset.

When the 'm' flag is not included in **'coptions'**, typing a character will immediately move the cursor back to where it belongs.

See the "sm" field in **'guicursor'** for setting the cursor shape and blinking when showing the match.

The **'matchpairs'** option can be used to specify the characters to show matches for. **'rightleft'** and **'revins'** are used to look for opposite matches.

Also see the matchparen plugin for highlighting the match when moving around [pi\\_paren.txt](#).

**Note:** Use of the short form is rated PG.

**'showmode' 'smd'** **'showmode' 'smd' 'nshowmode' 'nosmd'**  
boolean (Vim default: on, Vi default: off)  
global

If in Insert, Replace or Visual mode put a message on the last line. Use the 'M' flag in **'highlight'** to set the type of highlighting for this message.

When **XIM** may be used the message will include "XIM". But this doesn't mean XIM is really active, especially when **'imactivatekey'** is not set.

Whether or not to draw the signcolumn. Valid values are:  
"auto" only when there is a sign to display  
"no" never  
"yes" always  
"number" display signs in the **'number'** column. If the number column is not present, then behaves like "auto".

**'smartcase' 'scs'** **'smartcase' 'scs' 'nosmartcase' 'noscs'**  
boolean (default off)  
global

Override the **'ignorecase'** option if the search pattern contains upper case characters. Only used when the search pattern is typed and **'ignorecase'** option is on. Used for the commands "/", "?", "n", "N", ":g" and ":s". Not used for "\*", "#", "gd", tag search, etc. After "\*" and "#" you can make **'smartcase'** used by doing a "/" command, recalling the search pattern from history and hitting **<Enter>**.

**NOTE:** This option is reset when **'compatible'** is set.

**'smartindent' 'si'** **'smartindent' 'si' 'nosmartindent' 'nosi'**  
boolean (default off)  
local to buffer

Do smart autoindenting when starting a new line. Works for C-like programs, but can also be used for other languages. **'cindent'** does something like this, works better in most cases, but is more strict, see **C-indenting**. When **'cindent'** is on or **'indentexpr'** is set, setting **'si'** has no effect. **'indentexpr'** is a more advanced alternative.

Normally **'autoindent'** should also be on when using **'smartindent'**.

An indent is automatically inserted:

- After a line ending in '{'.
- After a line starting with a keyword from **'cinwords'**.
- Before a line starting with '}' (only with the "O" command).

When typing '}' as the first character in a new line, that line is given the same indent as the matching '{'.

When typing '#' as the first character in a new line, the indent for that line is removed, the '#' is put in the first column. The indent is restored for the next line. If you don't want this, use this mapping: **":inoremap # X^H#"**, where ^H is entered with **CTRL-V CTRL-H**. When using the ">>" command, lines starting with '#' are not shifted right.

**NOTE:** This option is reset when **'compatible'** is set.

This option is reset when **'paste'** is set and restored when **'paste'** is reset.

**'smarttab' 'sta'** **'smarttab' 'sta' 'nosmarttab' 'nosta'**  
boolean (default off)  
global

When on, a **<Tab>** in front of a line inserts blanks according to **'shiftwidth'**. **'tabstop'** or **'softtabstop'** is used in other places. A **<BS>** will delete a **'shiftwidth'** worth of space at the start of the line.

When off, a **<Tab>** always inserts blanks according to **'tabstop'** or **'softtabstop'**. **'shiftwidth'** is only used for shifting text left or right **shift-left-right**.

What gets inserted (a `<Tab>` or spaces) depends on the `'expandtab'` option. Also see `ins-expandtab` . When `'expandtab'` is not set, the number of spaces is minimized by using `<Tab>`s. This option is reset when `'paste'` is set and restored when `'paste'` is reset.

**NOTE:** This option is reset when `'compatible'` is set.

`'smoothscroll'` `'sms'` `'smoothscroll'` `'sms'` `'nosmoothscroll'` `'nosms'`  
boolean (default off)  
local to window

Scrolling works with screen lines. When `'wrap'` is set and the first line in the window wraps part of it may not be visible, as if it is above the window. "`<<<`" is displayed at the start of the first line, highlighted with `hl-NonText` .

You may also want to add "lastline" to the `'display'` option to show as much of the last line as possible.

**NOTE:** partly implemented, doesn't work yet for `gj` and `gk` .

`'softtabstop'` `'sts'` `'softtabstop'` `'sts'`  
number (default 0)  
local to buffer

Number of spaces that a `<Tab>` counts for while performing editing operations, like inserting a `<Tab>` or using `<BS>`. It "feels" like `<Tab>`s are being inserted, while in fact a mix of spaces and `<Tab>`s is used. This is useful to keep the `'ts'` setting at its standard value of 8, while being able to edit like it is set to `'sts'`. However, commands like "x" still work on the actual characters.

When `'sts'` is zero, this feature is off.

When `'sts'` is negative, the value of `'shiftwidth'` is used.

`'softtabstop'` is set to 0 when the `'paste'` option is set and restored when `'paste'` is reset.

See also `ins-expandtab` . When `'expandtab'` is not set, the number of spaces is minimized by using `<Tab>`s.

The 'L' flag in `'coptions'` changes how tabs are used when `'list'` is set.

**NOTE:** This option is set to 0 when `'compatible'` is set.

If Vim is compiled with the `+vartabs` feature then the value of `'softtabstop'` will be ignored if `'varsofttabstop'` is set to anything other than an empty string.

`'spell'` `'spell'` `'nospell'`  
boolean (default off)  
local to window  
{not available when compiled without the `+syntax` feature}

When on spell checking will be done. See `spell` .

The languages are specified with `'spelllang'`.

`'spellcapcheck'` `'spc'` `'spellcapcheck'` `'spc'`  
string (default "[.?!]\\_[\])'" \t]\+")  
local to buffer  
{not available when compiled without the `+syntax` feature}

Pattern to locate the end of a sentence. The following word will be checked to start with a capital letter. If not then it is highlighted with SpellCap `hl-SpellCap` (unless the word is also badly spelled). When this check is not wanted make this option empty.

Only used when `'spell'` is set.

Be careful with special characters, see `option-backslash` about including spaces and backslashes.

To set this option automatically depending on the language, see `set-spc-auto` .

`'spellfile' 'spf'` `'spellfile' 'spf'`  
string (default empty)  
local to buffer  
{not available when compiled without the `+syntax`  
feature}

Name of the word list file where words are added for the `zg` and `zw` commands. It must end in `".{encoding}.add"`. You need to include the path, otherwise the file is placed in the current directory.

The path may include characters from `'isfname'`, space, comma and `'@'`.

`E765`

It may also be a comma-separated list of names. A count before the `zg` and `zw` commands can be used to access each. This allows using a personal word list file and a project word list file.

When a word is added while this option is empty Vim will set it for you: Using the first directory in `'runtimepath'` that is writable. If there is no "spell" directory yet it will be created. For the file name the first language name that appears in `'spelllang'` is used, ignoring the region.

The resulting `".spl"` file will be used for spell checking, it does not have to appear in `'spelllang'`.

Normally one file is used for all regions, but you can add the region name if you want to. However, it will then only be used when `'spellfile'` is set to it, for entries in `'spelllang'` only files without region name will be found.

This option cannot be set from a `modeline` or in the `sandbox` , for security reasons.

`'spelllang' 'spl'` `'spelllang' 'spl'`  
string (default "en")  
local to buffer  
{not available when compiled without the `+syntax`  
feature}

A comma-separated list of word list names. When the `'spell'` option is on spellchecking will be done for these languages. Example:

`set spelllang=en_us,nl,medical`

This means US English, Dutch and medical words are recognized. Words that are not recognized will be highlighted.

The word list name must consist of alphanumeric characters, a dash or an underscore. It should not include a comma or dot. Using a dash is recommended to separate the two letter language name from a specification. Thus `"en-rare"` is used for rare English words.

A region name must come last and have the form `"_xx"`, where `"xx"` is the two-letter, lower case region name. You can use more than one region by listing them: `"en_us,en_ca"` supports both US and Canadian

English, but not words specific for Australia, New Zealand or Great Britain. (Note: currently en\_au and en\_nz dictionaries are older than en\_ca, en\_gb and en\_us).

If the name "cjk" is included East Asian characters are excluded from spell checking. This is useful when editing text that also has Asian words.

**Note** that the "medical" dictionary does not exist, it is just an example of a longer name.

E757

As a special case the name of a .spl file can be given as-is. The first "\_xx" in the name is removed and used as the region name (\_xx is an underscore, two letters and followed by a non-letter). This is mainly for testing purposes. You must make sure the correct encoding is used, Vim doesn't check it.

When **'encoding'** is set the word lists are reloaded. Thus it's a good idea to set **'spelllang'** after setting **'encoding'** to avoid loading the files twice.

How the related spell files are found is explained here: [spell-load](#) .

If the [spellfile.vim](#) plugin is active and you use a language name for which Vim cannot find the .spl file in **'runtimepath'** the plugin will ask you if you want to download the file.

After this option has been set successfully, Vim will source the files "spell/LANG.vim" in **'runtimepath'**. "LANG" is the value of **'spelllang'** up to the first character that is not an ASCII letter or number and not a dash. Also see [set-spc-auto](#) .

**'spelloptions'** **'spo'** string (default "")  
local to buffer  
{not available when compiled without the [+syntax](#) feature}

A comma-separated list of options for spell checking:

camel When a word is CamelCased, assume "Cased" is a separate word: every upper-case character in a word that comes after a lower case character indicates the start of a new word.

**'spellsuggest'** **'sps'** string (default "best")  
global  
{not available when compiled without the [+syntax](#) feature}

Methods used for spelling suggestions. Both for the [z=](#) command and the [spellsuggest\(\)](#) function. This is a comma-separated list of items:

best Internal method that works best for English. Finds changes like "fast" and uses a bit of sound-a-like scoring to improve the ordering.

double Internal method that uses two methods and mixes the results. The first method is "fast", the other method

computes how much the suggestion sounds like the bad word. That only works when the language specifies sound folding. Can be slow and doesn't always give better results.

`fast` Internal method that only checks for simple changes: character inserts/deletes/swaps. Works well for simple typing mistakes.

`{number}` The maximum number of suggestions listed for `z=`. Not used for `spellsuggest()`. The number of suggestions is never more than the value of `'lines'` minus two.

`timeout:{millisec}` Limit the time searching for suggestions to `{millisec}` milliseconds. Applies to the following methods. When omitted the limit is 5000. When negative there is no limit. {only works when built with the `+reltime` feature}

`file:{filename}` Read file `{filename}`, which must have two columns, separated by a slash. The first column contains the bad word, the second column the suggested good word. Example:

`theribal/terrible`

Use this for common mistakes that do not appear at the top of the suggestion list with the internal methods. Lines without a slash are ignored, use this for comments.

The word in the second column must be correct, otherwise it will not be used. Add the word to an ".add" file if it is currently flagged as a spelling mistake.

The file is used for all languages.

`expr:{expr}` Evaluate expression `{expr}`. Use a function to avoid trouble with spaces. Best is to call a function without arguments, see `expr-option-function`. `v:val` holds the badly spelled word. The expression must evaluate to a List of Lists, each with a suggestion and a score.

Example:

`[['the', 33], ['that', 44]]`

Set `'verbose'` and use `z=` to see the scores that the internal methods use. A lower score is better.

This may invoke `spellsuggest()` if you temporarily set `'spellsuggest'` to exclude the "expr:" part.

Errors are silently ignored, unless you set the `'verbose'` option to a non-zero value.

Only one of "best", "double" or "fast" may be used. The others may appear several times in any order. Example:

`:set sps=file:~/ .vim/sugg,best,expr:MySuggest()`

This option cannot be set from a `modeline` or in the `sandbox` , for security reasons.

`'splitbelow' 'sb'`            `'splitbelow'`   `'sb'`   `'nosplitbelow'`   `'nosb'`  
boolean (default off)  
global

When on, splitting a window will put the new window below the current one. `:split`

`'splitkeep' 'spk'`            `'splitkeep'`   `'spk'`  
string (default "cursor")  
global

The value of this option determines the scroll behavior when opening, closing or resizing horizontal splits.

Possible values are:

cursor            Keep the same relative cursor position.  
screen            Keep the text on the same screen line.  
topline           Keep the topline the same.

For the "screen" and "topline" values, the cursor position will be changed when necessary. In this case, the jumplist will be populated with the previous cursor position. For "screen", the text cannot always be kept on the same screen line when `'wrap'` is enabled.

`'splitright' 'spr'`            `'splitright'`   `'spr'`   `'nosplitright'`   `'nospr'`  
boolean (default off)  
global

When on, splitting a window will put the new window right of the current one. `:vsplit`

`'startofline' 'sol'`            `'startofline'`   `'sol'`   `'nostartofline'`   `'nosol'`  
boolean (default on)  
global

When "on" the commands listed below move the cursor to the first non-blank of the line. When off the cursor is kept in the same column (if possible). This applies to the commands:

- **CTRL-D**, **CTRL-U**, **CTRL-B**, **CTRL-F**, "G", "H", "M", "L", "gg"
- "d", "<<", "==" and ">>" with a linewise operator ( `operator-resulting-pos` )
- "%" with a count
- buffer changing commands (CTRL-^, `:bnext`, `:bNext`, etc.)
- Ex commands that only has a line number, e.g., `":25"` or `":+"`.

In case of buffer changing commands the cursor is placed at the column where it was the last time the buffer was edited.

**NOTE:** This option is set when `'compatible'` is set.

`'statusline' 'stl'`            `'statusline'`   `'stl'`   E540   E542  
string (default empty)  
global or local to window `global-local`  
{not available when compiled without the `+statusline`  
feature}

When non-empty, this option determines the content of the status line. Also see `status-line` .

The option consists of printf style '%' items interspersed with normal text. Each status line item is of the form:

```
%-0{minwid}.{maxwid}{item}
```

All fields except the {item} are optional. A single percent sign can be given as "%%".

**stl-%!**

When the option starts with "%!" then it is used as an expression, evaluated and the result is used as the option value. Example:

```
:set statusline=%!MyStatusLine()
```

The **g:statusline\_wid** variable will be set to the **window-ID** of the window that the status line belongs to.

The result can contain %{} items that will be evaluated too.

**Note** that the "%!" expression is evaluated in the context of the current window and buffer, while %{} items are evaluated in the context of the window that the statusline belongs to.

When there is error while evaluating the option then it will be made empty to avoid further errors. Otherwise screen updating would loop. When the result contains unprintable characters the result is unpredictable.

**Note** that the only effect of **'ruler'** when this option is set (and **'laststatus'** is 2) is controlling the output of **CTRL-G**.

field	meaning
-	Left justify the item. The default is right justified when minwid is larger than the length of the item.
0	Leading zeroes in numeric items. Overridden by '-'. Value must be 50 or less.
minwid	Minimum width of the item, padding as set by '-' & '0'.
maxwid	Maximum width of the item. Truncation occurs with a '<' on the left for text items. Numeric items will be shifted down to maxwid-2 digits followed by '>'number where number is the amount of missing digits, much like an exponential notation.
item	A one letter code as described below.

Following is a description of the possible statusline items. The second character in "item" is the type:

- N for number
- S for string
- F for flags as described below
- not applicable

item	meaning
f S	Path to the file in the buffer, as typed or relative to current directory.
F S	Full path to the file in the buffer.
t S	File name (tail) of file in the buffer.
m F	Modified flag, text is "[+]"; "[-]" if <b>'modifiable'</b> is off.
M F	Modified flag, text is ",+" or ",-".
r F	ReadOnly flag, text is "[RO]".

R F Readonly flag, text is ",RO".

h F Help buffer flag, text is "[help]".

H F Help buffer flag, text is ",HLP".

w F Preview window flag, text is "[Preview]".

W F Preview window flag, text is ",PRV".

y F Type of file in the buffer, e.g., "[vim]". See **'filetype'**.

Y F Type of file in the buffer, e.g., ",VIM". See **'filetype'**.

q S "[Quickfix List]", "[Location List]" or empty.

k S Value of "b:keymap\_name" or **'keymap'** when `:lmap` mappings are being used: "<keymap>"

n N Buffer number.

b N Value of character under cursor.

B N As above, in hexadecimal.

o N Byte number in file of byte under cursor, first byte is 1.  
Mnemonic: Offset from start of file (with one added)  
{not available when compiled without |+byte\_offset| feature}

O N As above, in hexadecimal.

NN Printer page number. (Only works in the **'printhead'** option.)

l N Line number.

L N Number of lines in buffer.

c N Column number (byte index).

v N Virtual column number (screen column).

V N Virtual column number as -{num}. Not displayed if equal to 'c'.

p N Percentage through file in lines as in **CTRL-G**.

P S Percentage through file of displayed window. This is like the percentage described for **'ruler'**. Always 3 in length, unless translated.

S S **'showcmd'** content, see **'showcmdloc'**.

a S Argument list status as in default title. ({current} of {max})  
Empty if the argument file count is zero or one.

{ NF Evaluate expression between '%{' and '}' and substitute result.  
**Note** that there is no '%' before the closing '}'. The expression cannot contain a '}' character, call a function to work around that. See `stl-%{` below.

{% - This is almost same as { except the result of the expression is re-evaluated as a statusline format string. Thus if the return value of expr contains % items they will get expanded. The expression can contain the } character, the end of expression is denoted by %}.  
For example:  
    func! Stl\_filename() abort  
        return "%t"  
    endfunc  
    `stl=%{Stl\_filename()}` results in `"%t"`  
    `stl=%{%Stl\_filename()}` results in `"Name of current file"`

%} - End of `{%` expression

( - Start of item group. Can be used for setting the width and alignment of a section. Must be followed by %) somewhere.

) - End of item group. No width fields allowed.

T N For **'tabline'**: start of tab page N label. Use %T after the last label. This information is used for mouse clicks.

X N For **'tabline'**: start of close tab N label. Use %X after the label, e.g.: %3Xclose%X. Use %999X for a "close current tab" mark. This information is used for mouse clicks.

- < - Where to truncate line if too long. Default is at the start. No width fields allowed.
- = - Separation point between alignment sections. Each section will be separated by an equal number of spaces. With one %= what comes after it will be right-aligned. With two %= there is a middle part, with white space left and right of it. No width fields allowed.
- # - Set highlight group. The name must follow and then a # again. Thus use %#HLname# for highlight group HLname. The same highlighting is used, also for the statusline of non-current windows.
- \* - Set highlight group to User{N}, where {N} is taken from the minwid field, e.g. %1\*. Restore normal highlight with %\* or %0\*. The difference between User{N} and StatusLine will be applied to StatusLineNC for the statusline of non-current windows. The number N must be between 1 and 9. See [hl-User1..9](#)

When displaying a flag, Vim removes the leading comma, if any, when that flag comes right after plaintext. This will make a nice display when flags are used like in the examples below.

When all items in a group becomes an empty string (i.e. flags that are not set) and a minwid is not set for the group, the whole group will become empty. This will make a group like the following disappear completely from the statusline when none of the flags are set.

```
:set statusline=...%(\ [%M%R%H]%)...
```

Beware that an expression is evaluated each and every time the status line is displayed.

```
stl-%{ g:actual_curbuf g:actual_curwin
```

While evaluating %{} the current buffer and current window will be set temporarily to that of the window (and buffer) whose statusline is currently being drawn. The expression will evaluate in this context. The variable "g:actual\_curbuf" is set to the `bufnr()` number of the real current buffer and "g:actual\_curwin" to the `window-ID` of the real current window. These values are strings.

The **'statusline'** option will be evaluated in the `sandbox` if set from a modeline, see [sandbox-option](#) .

This option cannot be set in a modeline when **'modelineexpr'** is off.

It is not allowed to change text or jump to another window while evaluating **'statusline'** `textlock` .

If the statusline is not updated when you want it (e.g., after setting a variable that's used in an expression), you can force an update by using `:redrawstatus``.

A result of all digits is regarded a number for display purposes. Otherwise the result is taken as flag text and applied to the rules described above.

Watch out for errors in expressions. They may render Vim unusable! If you are stuck, hold down ':' or 'Q' to get a prompt, then quit and edit your .vimrc or whatever with "vim --clean" to get it right.

Examples:

Emulate standard status line with **'ruler'** set

```
:set statusline=%<%f\ %h%w%m%r%=%-14.(%l,%c%V%)\ %P
```

Similar, but add ASCII value of char under the cursor (like "ga")

```
:set statusline=%<%f%h%m%r%=%b\ 0x%B\ \ %l,%c%V\ %P
```

Display byte count and byte value, modified flag in red.

```
:set statusline=%<%f%=\ [%1*M%*%n%R%H]\ %-19(%3l,%02c%03V%)%0'%02b'
```

```
:hi User1 term=inverse,bold cterm=inverse,bold ctermfg=red
```

Display a ,GZ flag if a compressed file is loaded

```
:set statusline=...%r%{VarExists('b:gzflag','\ [GZ]')}%h...
```

In the `:autocmd 's:`

```
:let b:gzflag = 1
```

And:

```
:unlet b:gzflag
```

And define this function:

```
:function VarExists(var, val)
: if exists(a:var) | return a:val | else | return '' | endif
:endifunction
```

```
'suffixes' 'su' string (default ".bak,~, .o, .h, .info, .swp, .obj")
 global
```

Files with these suffixes get a lower priority when multiple files match a wildcard. See [suffixes](#) . Commas can be used to separate the suffixes. Spaces after the comma are ignored. A dot is also seen as the start of a suffix. To avoid a dot or comma being recognized as a separator, precede it with a backslash (see [option-backslash](#) about including spaces and backslashes).

See **'wildignore'** for completely ignoring files.

The use of `:set+=` and `:set-=` is preferred when adding or removing suffixes from the list. This avoids problems when a future version uses another default.

```
'suffixesadd' 'sua' string (default "")
 local to buffer
 'suffixesadd' 'sua'
```

Comma-separated list of suffixes, which are used when searching for a file for the "gf", "[I", etc. commands. Example:

```
:set suffixesadd=.java
```

```
'swapfile' 'swf' boolean (default on)
 local to buffer
 'swapfile' 'swf' 'noswapfile' 'noswf'
```

Use a swapfile for the buffer. This option can be reset when a swapfile is not wanted for a specific buffer. For example, with confidential information that even root must not be able to access. Careful: All text will be in memory:

- Don't use this for big files.
- Recovery will be impossible!

A swapfile will only be present when **'updatecount'** is non-zero and **'swapfile'** is set.

When **'swapfile'** is reset, the swap file for the current buffer is immediately deleted. When **'swapfile'** is set, and **'updatecount'** is

non-zero, a swap file is immediately created. Also see `swap-file` and `'swapsync'`. If you want to open a new buffer without creating a swap file for it, use the `:noswapfile` modifier. See `'directory'` for where the swap file is created.

This option is used together with `'bufhidden'` and `'buftype'` to specify special kinds of buffers. See `special-buffers`.

`'swapsync'` `'sws'` string (default "fsync")  
`'swapsync'` `'sws'`  
 global

When this option is not empty a swap file is synced to disk after writing to it. This takes some time, especially on busy unix systems. When this option is empty parts of the swap file may be in memory and not written to disk. When the system crashes you may lose more work. On Unix the system does a sync now and then without Vim asking for it, so the disadvantage of setting this option off is small. On some systems the swap file will not be written at all. For a unix system setting it to "sync" will use the sync() call instead of the default fsync(), which may work better on some systems. The `'fsync'` option is used for the actual file.

`'switchbuf'` `'swb'` string (default "")  
`'switchbuf'` `'swb'`  
 global

This option controls the behavior when switching between buffers. This option is checked, when

- jumping to errors with the `quickfix` commands (`:cc`, `:cn`, `:cp`, etc.).
- jumping to a tag using the `:stag` command.
- opening a file using the `CTRL-W_f` or `CTRL-W_F` command.
- jumping to a buffer using a buffer split command (e.g. `:sbuffer`, `:sbnext`, or `:sbrewind`).

Possible values (comma-separated list):

- `useopen` If included, jump to the first open window in the current tab page that contains the specified buffer (if there is one). Otherwise: Do not examine other windows.
- `usetab` Like "useopen", but also consider windows in other tab pages.
- `split` If included, split the current window before loading a buffer for a `quickfix` command that display errors. Otherwise: do not split, use current window (when used in the quickfix window: the previously used window or split if there is no other window).
- `vsplit` Just like "split" but split vertically.
- `newtab` Like "split", but open a new tab page. Overrides "split" when both are present.
- `uselast` If included, jump to the previously used window when jumping to errors with `quickfix` commands.

If a window has `'winfixbuf'` enabled, `'switchbuf'` is currently not applied to the split window.

**'synmaxcol' 'smc'**                    **'synmaxcol'**    **'smc'**  
                                          number (default 3000)  
                                          local to buffer  
                                          {not available when compiled without the **+syntax**  
                                          feature}

Maximum column in which to search for syntax items. In long lines the text after this column is not highlighted and following lines may not be highlighted correctly, because the syntax state is cleared. This helps to avoid very slow redrawing for an XML file that is one long line.  
Set to zero to remove the limit.

**'syntax' 'syn'**                        **'syntax'**    **'syn'**  
                                          string (default empty)  
                                          local to buffer    **local-noglobal**  
                                          {not available when compiled without the **+syntax**  
                                          feature}

When this option is set, the syntax with this name is loaded, unless syntax highlighting has been switched off with `":syntax off"`. Otherwise this option does not always reflect the current syntax (the `b:current_syntax` variable does). This option is most useful in a modeline, for a file which syntax is not automatically recognized. Example, in an IDL file:

```
/* vim: set syntax=idl : */
```

When a dot appears in the value then this separates two filetype names. Example:

```
/* vim: set syntax=c.doxygen : */
```

This will use the "c" syntax first, then the "doxygen" syntax.

**Note** that the second one must be prepared to be loaded as an addition, otherwise it will be skipped. More than one dot may appear.

To switch off syntax highlighting for the current file, use:

```
:set syntax=OFF
```

To switch syntax highlighting on according to the current value of the **'filetype'** option:

```
:set syntax=ON
```

What actually happens when setting the **'syntax'** option is that the Syntax autocommand event is triggered with the value as argument.

This option is not copied to another buffer, independent of the 's' or 'S' flag in **'coptions'**.

Only alphanumeric characters, '.', '-' and '\_' can be used.

**'tabclose' 'tcl'**                        **'tabclose'**    **'tcl'**  
                                          string (default "")  
                                          global

This option controls the behavior when closing tab pages (e.g., using **:tabclose** ). When empty Vim goes to the next (right) tab page.

Possible values (comma-separated list):

left                    If included, go to the previous tab page instead of the next one.  
uselast                If included, go to the previously used tab page if possible. This option takes precedence over the others.

**'tabline'** **'tal'** string (default empty) 'tabline' 'tal'  
global  
When non-empty, this option determines the content of the tab pages line at the top of the Vim window. When empty Vim will use a default tab pages line. See [setting-tabline](#) for more info.

The tab pages line only appears as specified with the **'showtabline'** option and only when there is no GUI tab line. When 'e' is in **'guioptions'** and the GUI supports a tab line **'guitablabel'** is used instead. **Note** that the two tab pages lines are very different.

The value is evaluated like with **'statusline'**. You can use [tabpagenr\(\)](#), [tabpagewinnr\(\)](#) and [tabpagebuflist\(\)](#) to figure out the text to be displayed. Use "%1T" for the first label, "%2T" for the second one, etc. Use "%X" items for closing labels.

When changing something that is used in **'tabline'** that does not trigger it to be updated, use [:redrawtabline](#). This option cannot be set in a modeline when **'modelineexpr'** is off.

Keep in mind that only one of the tab pages is the current one, others are invisible and you can't jump to their windows.

**'tabpagemax'** **'tpm'** number (default 10) 'tabpagemax' 'tpm'  
global  
Maximum number of tab pages to be opened by the `-p` command line argument or the `":tab all"` command. [tabpage](#)

**'tabstop'** **'ts'** number (default 8) 'tabstop' 'ts'  
local to buffer  
Number of spaces that a `<Tab>` in the file counts for. Also see the [:retab](#) command, and the **'softtabstop'** option.

**Note:** Setting **'tabstop'** to any other value than 8 can make your file appear wrong in many places, e.g., when printing it. The value must be more than 0 and less than 10000.

There are five main ways to use tabs in Vim:

1. Always keep **'tabstop'** at 8, set **'softtabstop'** and **'shiftwidth'** to 4 (or 3 or whatever you prefer) and use **'noexpandtab'**. Then Vim will use a mix of tabs and spaces, but typing `<Tab>` and `<BS>` will behave like a tab appears every 4 (or 3) characters. This is the recommended way, the file will look the same with other tools and when listing it in a terminal.
2. Set **'softtabstop'** and **'shiftwidth'** to whatever you prefer and use **'expandtab'**. This way you will always insert spaces. The formatting will never be messed up when **'tabstop'** is changed (leave it at 8 just in case). The file will be a bit larger. You do need to check if no Tabs exist in the file. You can get rid of them by first setting **'expandtab'** and using ``%retab!``, making sure the value of **'tabstop'** is set correctly.

3. Set `'tabstop'` and `'shiftwidth'` to whatever you prefer and use `'expandtab'`. This way you will always insert spaces. The formatting will never be messed up when `'tabstop'` is changed. You do need to check if no Tabs exist in the file, just like in the item just above.
4. Set `'tabstop'` and `'shiftwidth'` to whatever you prefer and use a `modeline` to set these values when editing the file again. Only works when using Vim to edit the file, other tools assume a tabstop is worth 8 spaces.
5. Always set `'tabstop'` and `'shiftwidth'` to the same value, and `'noexpandtab'`. This should then work (for initial indents only) for any tabstop setting that people use. It might be nice to have tabs after the first non-blank inserted as spaces if you do this though. Otherwise aligned comments will be wrong when `'tabstop'` is changed.

If Vim is compiled with the `+vartabs` feature then the value of `'tabstop'` will be ignored if `'vartabstop'` is set to anything other than an empty string.

<code>'tagbsearch'</code>	<code>'tbs'</code>	<code>'tagbsearch'</code>	<code>'tbs'</code>	<code>'notagbsearch'</code>	<code>'notbs'</code>
<code>'tagbsearch'</code>	<code>'tbs'</code>	boolean (default on)			
		global			

When searching for a tag (e.g., for the `:ta` command), Vim can either use a binary search or a linear search in a tags file. Binary searching makes searching for a tag a LOT faster, but a linear search will find more tags if the tags file wasn't properly sorted. Vim normally assumes that your tags files are sorted, or indicate that they are not sorted. Only when this is not the case does the `'tagbsearch'` option need to be switched off.

When `'tagbsearch'` is on, binary searching is first used in the tags files. In certain situations, Vim will do a linear search instead for certain files, or retry all files with a linear search. When `'tagbsearch'` is off, only a linear search is done.

Linear searching is done anyway, for one file, when Vim finds a line at the start of the file indicating that it's not sorted:

```
!_TAG_FILE_SORTED 0 /some comment/
```

[The whitespace before and after the '0' must be a single `<Tab>`]

When a binary search was done and no match was found in any of the files listed in `'tags'`, and case is ignored or a pattern is used instead of a normal tag name, a retry is done with a linear search. Tags in unsorted tags files, and matches with different case will only be found in the retry.

If a tag file indicates that it is case-fold sorted, the second, linear search can be avoided when case is ignored. Use a value of '2' in the `"!_TAG_FILE_SORTED"` line for this. A tag file can be case-fold sorted with the `-f` switch to `"sort"` in most unices, as in the command: `"sort -f -o tags tags"`. For Universal ctags and Exuberant ctags version 5.x or higher (at least 5.5) the `--sort=foldcase` switch can be used for this as well. **Note** that case must be folded to uppercase for

this to work.

By default, tag searches are case-sensitive. Case is ignored when **'ignorecase'** is set and **'tagcase'** is "followic", or when **'tagcase'** is "ignore".

Also when **'tagcase'** is "followscs" and **'smartcase'** is set, or **'tagcase'** is "smart", and the pattern contains only lowercase characters.

When **'tagbsearch'** is off, tags searching is slower when a full match exists, but faster when no full match exists. Tags in unsorted tags files may only be found with **'tagbsearch'** off.

When the tags file is not sorted, or sorted in a wrong way (not on ASCII byte value), **'tagbsearch'** should be off, or the line given above must be included in the tags file.

This option doesn't affect commands that find all matching tags (e.g., command-line completion and ":help").

**'tagcase'** **'tc'** **'tagcase'** **'tc'**  
string (default "followic")  
global or local to buffer [global-local](#)

This option specifies how case is handled when searching the tags file:

followic	Follow the <b>'ignorecase'</b> option
followscs	Follow the <b>'smartcase'</b> and <b>'ignorecase'</b> options
ignore	Ignore case
match	Match case
smart	Ignore case unless an upper case letter is used

**NOTE:** This option is set to the Vi default value when **'compatible'** is set and to the Vim default value when **'compatible'** is reset.

**'tagfunc'** **'tfu'** **'tagfunc'** **'tfu'**  
string (default: empty)  
local to buffer  
{not available when compiled without the [+eval](#) feature}

This option specifies a function to be used to perform tag searches. The function gets the tag pattern and should return a List of matching tags. See [tag-function](#) for an explanation of how to write the function and an example. The value can be the name of a function, a [lambda](#) or a [Funcref](#). See [option-value-function](#) for more information.

This option cannot be set from a [modeline](#) or in the [sandbox](#), for security reasons.

**'taglength'** **'tl'** **'taglength'** **'tl'**  
number (default 0)  
global

If non-zero, tags are significant up to this number of characters.

**'tagrelative'** **'tr'** **'tagrelative'** **'tr'** **'notagrelative'** **'notr'**  
boolean (Vim default: on, Vi default: off)  
global

If on and using a tags file in another directory, file names in that

tags file are relative to the directory where the tags file is.  
**NOTE:** This option is set to the Vi default value when **'compatible'** is set and to the Vim default value when **'compatible'** is reset.

**'tags'** **'tag'** 'tags' 'tag' E433  
string (default `"/tags,tags"`, when compiled with  
`+emacs_tags` : `"/tags,./TAGS,tags,TAGS"`)  
global or local to buffer `global-local`

Filenames for the tag command, separated by spaces or commas. To include a space or comma in a file name, precede it with backslashes (see `option-backslash` about including spaces/commas and backslashes). When a file name starts with `"/"`, the `"/` is replaced with the path of the current file. But only when the `'d'` flag is not included in **'cptions'**. Environment variables are expanded `:set_env` . Also see `tags-option` .

`"*`, `**` and other wildcards can be used to search for tags files in a directory tree. See `file-searching` . E.g., `"/lib/**/tags"` will find all files named `tags` below `"/lib"`. The filename itself cannot contain wildcards, it is used as-is. E.g., `"/lib/**/tags?"` will find files called `tags?`.

The `tagfiles()` function can be used to get a list of the file names actually used.

If Vim was compiled with the `+emacs_tags` feature, Emacs-style tag files are also supported. They are automatically recognized. The default value becomes `"/tags,./TAGS,tags,TAGS"`, unless case differences are ignored (MS-Windows). `emacs-tags`

The use of `:set+=` and `:set-=` is preferred when adding or removing file names from the list. This avoids problems when a future version uses another default.

**'tagstack'** **'tgst'** 'tagstack' 'tgst' 'notagstack' 'notgst'  
boolean (default on)  
global

When on, the `tagstack` is used normally. When off, a `":tag"` or `":tselect"` command with an argument will not push the tag onto the tagstack. A following `":tag"` without an argument, a `":pop"` command or any other command that uses the tagstack will use the unmodified tagstack, but does change the pointer to the active entry. Resetting this option is useful when using a `":tag"` command in a mapping which should not change the tagstack.

**'tcldll'** 'tcldll'  
string (default depends on the build)  
global  
{only available when compiled with the `+tcl/dyn` feature}

Specifies the name of the Tcl shared library. The default is `DYNAMIC_TCL_DLL`, which was specified at compile time.

Environment variables are expanded `:set_env` .

This option cannot be set from a `modeline` or in the `sandbox` , for security reasons.

**'term'** 'term' E529 E530 E531  
string (default is `$TERM`, if that fails:

```

in the GUI: "builtin_gui"
 on Amiga: "amiga"
 on Haiku: "xterm"
 on Mac: "mac-ansi"
 on Unix: "ansi"
 on VMS: "ansi"
 on Win 32: "win32")

```

global

Name of the terminal. Used for choosing the terminal control characters. Environment variables are expanded `:set_env` .

For example:

```
:set term=$TERM
```

See `termcap` .

```

'termbidi' 'tbidi'
'notermbidi' 'notbidi'

```

**'termbidi' 'tbidi'** boolean (default off, on for "mlterm")

global

{only available when compiled with the `+arabic` feature}

The terminal is in charge of Bi-directionality of text (as specified by Unicode). The terminal is also expected to do the required shaping that some languages (such as Arabic) require.

Setting this option implies that **'rightleft'** will not be set when **'arabic'** is set and the value of **'arabicshape'** will be ignored.

**Note** that setting **'termbidi'** has the immediate effect that **'arabicshape'** is ignored, but **'rightleft'** isn't changed automatically. This option is reset when the GUI is started.

For further details see `arabic.txt` .

```

'termencoding' 'tenc'

```

**'termencoding' 'tenc'** string (default ""; with GTK+ GUI: "utf-8")

global

Encoding used for the terminal. This specifies what character encoding the keyboard produces and the display will understand. For the GUI it only applies to the keyboard ('encoding' is used for the display).

**E617 E950**

**Note:** This does not apply to the GTK+ GUI. After the GUI has been successfully initialized, **'termencoding'** is forcibly set to "utf-8". Any attempts to set a different value will be rejected, and an error message is shown.

For the Win32 GUI and console versions **'termencoding'** is not used, because the Win32 system always passes Unicode characters.

When empty, the same encoding is used as for the **'encoding'** option. This is the normal value.

Not all combinations for **'termencoding'** and **'encoding'** are valid. See `encoding-table` .

The value for this option must be supported by internal conversions or `iconv()`. When this is not possible no conversion will be done and you will probably experience problems with non-ASCII characters.

Example: You are working with the locale set to euc-jp (Japanese) and want to edit a UTF-8 file:

```
:let &termencoding = &encoding
```

```
:set encoding=utf-8
```

You need to do this when your system has no locale support for UTF-8.

```
'termguicolors' 'tgc' 'notermguicolors' 'notgc' E954
'termguicolors' 'tgc' boolean (default off unless Vim detects that it runs
 in a capable terminal)
 global
 {not available when compiled without the
 +termguicolors feature}
```

When on, uses `highlight-guifg` and `highlight-guibg` attributes in the terminal (thus using 24-bit color).

Requires a ISO-8613-3 compatible terminal. If setting this option does not work (produces a colorless UI) reading `xterm-true-color` might help.

For Win32 console, Windows 10 version 1703 (Creators Update) or later is required. Use this check to find out:

```
if has('vcon')
```

This requires Vim to be built with the `+vtp` feature.

**Note** that the "cterm" attributes are still used, not the "gui" ones.

When using Vim with Windows Terminal, the background of Windows Terminal is normally filled with the Vim background color. Setting `'termguicolors'` and the `guibg` of the Normal highlight group to NONE will make the background transparent:

```
:hi Normal guibg=NONE
```

**NOTE:** This option is reset when `'compatible'` is set.

```
'termwinkey' 'twk' string (default "")
 local to window
 'termwinkey' 'twk'
```

The key that starts a **CTRL-W** command in a terminal window. Other keys are sent to the job running in the window.

The key can be specified as a single character, a `key-notation` (e.g. `<Up>`, `<C-F>`) or a letter preceded with a caret (e.g. `^F` is **CTRL-F**):

```
:set twk=X
:set twk=^I
:set twk=<C-L>
```

The string must be one key stroke but can be multiple bytes.

When not set **CTRL-W** is used, so that **CTRL-W** : gets you to the command line. If `'termwinkey'` is set to **CTRL-L** then **CTRL-L** : gets you to the command line.

```
'termwincscroll' 'tws' number (default 10000)
 local to buffer
 {not available when compiled without the
 +terminal feature}
 'termwincscroll' 'twsl'
```

Number of scrollback lines to keep. When going over this limit the first 10% of the scrollback lines are deleted. This is just to reduce the memory usage. See `Terminal-Normal` .

Also used as a limit for text sent to the terminal in one write, multiplied by the number of columns times 3 (average number of bytes per cell).

**'termwintype'** **'twt'** string (default "")  
local to window

**'termwintype'** **'twt'** string (default "")  
local to window

Size used when opening the `terminal` window. Format:  
`{rows}x{columns}` or `{rows}*{columns}`.

- When empty the terminal gets the size from the window.
- When set with a "x" (e.g., "24x80") the terminal size is not adjusted to the window size. If the window is smaller only the top-left part is displayed.
- When set with a "\*" (e.g., "10\*50") the terminal size follows the window size, but will not be smaller than the specified rows and/or columns.
- When rows is zero then use the height of the window.
- When columns is zero then use the width of the window.
- Using "0x0" or "0\*0" is the same as empty.
- Can be overruled in the `term_start()` options with "term\_rows" and "term\_cols".

Examples:

"30x0" uses 30 rows and the current window width.

"20\*0" uses at least 20 rows and the current window width.

"0\*40" uses the current window height and at least 40 columns.

**Note** that the command running in the terminal window may still change the size of the terminal. In that case the Vim window will be adjusted to that size, if possible.

**'termwintype'** **'twt'** string (default "")  
global  
{only available when compiled with the `terminal` feature on MS-Windows}

Specify the virtual console (pty) used when opening the terminal window.

Possible values are:

"" use ConPTY if it is stable, winpty otherwise

"winpty" use winpty, fail if not supported

"conpty" use `ConPTY` , fail if not supported

`ConPTY` support depends on the platform. Windows 10 October 2018 Update is the first version that supports `ConPTY`, however it is still considered unstable. `ConPTY` might become stable in the next release of Windows 10. `winpty` support needs to be installed. If neither is supported then you cannot open a terminal window.

**'terse'** boolean (default off)  
global

**'terse'** **'noterse'**

When set: Add 's' flag to **'shortmess'** option (this makes the message for a search that hits the start or end of the file not being

displayed). When reset: Remove 's' flag from **'shortmess'** option. {Vi shortens a lot of messages}

**'textauto'** **'ta'** **'textauto'** **'ta'** **'notextauto'** **'nota'**  
boolean (Vim default: on, Vi default: off)  
global

This option is obsolete. Use **'fileformats'**.

For backwards compatibility, when **'textauto'** is set, **'fileformats'** is set to the default value for the current system. When **'textauto'** is reset, **'fileformats'** is made empty.

**NOTE:** This option is set to the Vi default value when **'compatible'** is set and to the Vim default value when **'compatible'** is reset.

**'textmode'** **'tx'** **'textmode'** **'tx'** **'notextmode'** **'notx'**  
boolean (Win32: default on,  
others: default off)  
local to buffer

This option is obsolete. Use **'fileformat'**.

For backwards compatibility, when **'textmode'** is set, **'fileformat'** is set to "dos". When **'textmode'** is reset, **'fileformat'** is set to "unix".

**'textwidth'** **'tw'** **'textwidth'** **'tw'**  
number (default 0)  
local to buffer

Maximum width of text that is being inserted. A longer line will be broken after white space to get this width. A zero value disables this.

**'textwidth'** is set to 0 when the **'paste'** option is set and restored when **'paste'** is reset.

When **'textwidth'** is zero, **'wrapmargin'** may be used. See also **'formatoptions'** and `ins-textwidth`.

When **'formatexpr'** is set it will be used to break the line.

**NOTE:** This option is set to 0 when **'compatible'** is set.

**'thesaurus'** **'tsr'** **'thesaurus'** **'tsr'**  
string (default "")  
global or local to buffer `global-local`  
List of file names, separated by commas, that are used to lookup words for thesaurus completion commands `i_CTRL-X_CTRL-T`. See `compl-thesaurus`.

This option is not used if **'thesaurusfunc'** is set, either for the buffer or globally.

To include a comma in a file name precede it with a backslash. Spaces after a comma are ignored, otherwise spaces are included in the file name. See `option-backslash` about using backslashes. The use of `:set+=` and `:set-=` is preferred when adding or removing directories from the list. This avoids problems when a future version uses another default. Backticks cannot be used in this option for security reasons.

**'thesaurusfunc'** **'tsrfu'**

**'thesaurusfunc'** **'tsrfu'** string (default: empty)  
global or local to buffer `global-local`  
{not available when compiled without the `+eval`  
feature}

This option specifies a function to be used for thesaurus completion with **CTRL-X CTRL-T**. `i_CTRL-X_CTRL-T` See `compl-thesaurusfunc`. The value can be the name of a function, a `lambda` or a `Funcref`. See `option-value-function` for more information.

This option cannot be set from a `modeline` or in the `sandbox`, for security reasons.

**'tildeop'** **'top'** **'tildeop'** **'top'** **'notildeop'** **'notop'**  
boolean (default off)  
global

When on: The tilde command "`~`" behaves like an operator.

**NOTE:** This option is reset when **'compatible'** is set.

**'timeout'** **'to'** **'timeout'** **'to'** **'notimeout'** **'noto'**  
boolean (default on)  
global

**'ttimeout'** **'ttimeout'** **'ttimeout'** **'nottimeout'**  
boolean (default off, set in `defaults.vim`)  
global

These two options together determine the behavior when part of a mapped key sequence or keyboard code has been received:

<b>'timeout'</b>	<b>'ttimeout'</b>	action
off	off	do not time out
on	on or off	time out on <code>:mappings</code> and key codes
off	on	time out on key codes

If both options are off, Vim will wait until either the complete mapping or key sequence has been received, or it is clear that there is no mapping or key sequence for the received characters. For example: if you have mapped "`vl`" and Vim has received '`v`', the next character is needed to see if the '`v`' is followed by an '`l`'.

When one of the options is on, Vim will wait for about 1 second for the next character to arrive. After that the already received characters are interpreted as single characters. The waiting time can be changed with the **'timeoutlen'** option.

On slow terminals or very busy systems timing out may cause malfunctioning cursor keys. If both options are off, Vim waits forever after an entered `<Esc>` if there are key codes that start with `<Esc>`. You will have to type `<Esc>` twice. If you do not have problems with key codes, but would like to have `:mapped` key sequences not timing out in 1 second, set the **'ttimeout'** option and reset the **'timeout'** option.

**NOTE:** **'ttimeout'** is reset when **'compatible'** is set.

**'timeoutlen'** **'tm'** **'timeoutlen'** **'tm'**  
number (default 1000)

global

**'timeoutlen'** **'ttm'** number (default -1, set to 100 in `defaults.vim`)  
global

The time in milliseconds that is waited for a key code or mapped key sequence to complete. Also used for `CTRL-\ CTRL-N` and `CTRL-\ CTRL-G` when part of a command has been typed.

Normally only **'timeoutlen'** is used and **'ttimeoutlen'** is -1. When a different timeout value for key codes is desired set **'ttimeoutlen'** to a non-negative number.

<code>timeoutlen</code>	mapping delay	key code delay
< 0	<b>'timeoutlen'</b>	<b>'timeoutlen'</b>
>= 0	<b>'timeoutlen'</b>	<b>'ttimeoutlen'</b>

The timeout only happens when the **'timeout'** and **'ttimeout'** options tell so. A useful setting would be

```
:set timeout timeoutlen=3000 ttimeoutlen=100
```

(time out on mapping after three seconds, time out on key codes after a tenth of a second).

**'title'** boolean (default off, on when title can be restored)  
global

When on, the title of the window will be set to the value of **'titlestring'** (if it is not empty), or to:

```
filename [+--] (path) - VIM
```

Where:

filename	the name of the file being edited
-	indicates the file cannot be modified, <b>'ma'</b> off
+	indicates the file was modified
=	indicates the file is read-only
+=	indicates the file is read-only and modified
(path)	is the path of the file being edited
- VIM	the server name <code>v:servername</code> or "VIM"

Only works if the terminal supports setting window titles (currently Amiga console, Win32 console, all GUI versions and terminals with a non-empty **'t\_ts'** option - these are Unix xterm and iris-ansi by default, where **'t\_ts'** is taken from the builtin termcap).

X11

When Vim was compiled with HAVE\_X11 defined, the original title will be restored if possible. The output of `":version"` will include `"+X11"` when HAVE\_X11 was defined, otherwise it will be `"-X11"`. This also works for the icon name **'icon'**.

But: When Vim was started with the `-X` argument, restoring the title will not work (except in the GUI).

If the title cannot be restored, it is set to the value of **'titleold'**. You might want to restore the title outside of Vim then.

When using an xterm from a remote machine you can use this command:

```
rsh machine_name xterm -display $DISPLAY &
ssh -X machine_name xterm &
```

then the WINDOWID environment variable should be inherited and the title of the window should change back to what it should be after exiting Vim.

**'titlelen'** 'titlelen'  
number (default 85)  
global  
Gives the percentage of **'columns'** to use for the length of the window title. When the title is longer, only the end of the path name is shown. A '<' character before the path name is used to indicate this. Using a percentage makes this adapt to the width of the window. But it won't work perfectly, because the actual number of characters available also depends on the font used and other things in the title bar. When **'titlelen'** is zero the full path is used. Otherwise, values from 1 to 30000 percent can be used.  
**'titlelen'** is also used for the **'titlestring'** option.

**'titleold'** 'titleold'  
string (default "Thanks for flying Vim")  
global  
This option will be used for the window title when exiting Vim if the original title cannot be restored. Only happens if **'title'** is on or **'titlestring'** is not empty.  
This option cannot be set from a **modeline** or in the **sandbox** , for security reasons.

**'titlestring'** 'titlestring'  
string (default "")  
global  
When this option is not empty, it will be used for the title of the window. This happens only when the **'title'** option is on. Only works if the terminal supports setting window titles (currently Amiga console, Win32 console, all GUI versions and terminals with a non-empty **'t\_ts'** option).  
When Vim was compiled with HAVE\_X11 defined, the original title will be restored if possible, see **X11** .  
  
When this option contains printf-style '%' items, they will be expanded according to the rules used for **'statusline'**. If it contains an invalid '%' format, the value is used as-is and no error or warning will be given when the value is set.  
This option cannot be set in a modeline when **'modelineexpr'** is off.

Example:

```
:auto BufEnter * let &titlestring = hostname() .. "/" .. expand("%:p")
:set title titlestring=%<%F%=%l/%L-%P titlelen=70
```

The value of **'titlelen'** is used to align items in the middle or right of the available space.

Some people prefer to have the file name first:

```
:set titlestring=%t%(\ %M%)(\ (%{expand("\%:~::~:h")})%)(\ %a%)
```

**Note** the use of "%{ }" and an expression to get the path of the file, without the file name. The "%( %)" constructs are used to add a separating space only when needed.

**NOTE:** Use of special characters in **'titlestring'** may cause the display to be garbled (e.g., when it contains a CR or NL character).

{not available when compiled without the |+statusline| feature}

**'toolbar'** **'tb'** string (default "icons, tooltips")  
global  
{only for |+GUI\_GTK|, |+GUI\_Motif| and |+GUI\_Photon|}

The contents of this option controls various toolbar settings. The possible values are:

icons	Toolbar buttons are shown with icons.
text	Toolbar buttons shown with text.
horiz	Icon and text of a toolbar button are horizontally arranged. {only in GTK+ 2 GUI}
tooltips	Tooltips are active for toolbar buttons.

Tooltips refer to the popup help text which appears after the mouse cursor is placed over a toolbar button for a brief moment.

If you want the toolbar to be shown with icons as well as text, do the following:

```
:set tb=icons,text
```

Motif cannot display icons and text at the same time. They will show icons if both are requested.

If none of the strings specified in **'toolbar'** are valid or if **'toolbar'** is empty, this option is ignored. If you want to disable the toolbar, you need to set the **'guioptions'** option. For example:

```
:set guioptions-=T
```

Also see [gui-toolbar](#) .

**'toolbariconsize'** **'tbis'** string (default "small")  
global  
{only in the GTK+ GUI}

Controls the size of toolbar icons. The possible values are:

tiny	Use tiny icons.
small	Use small icons (default).
medium	Use medium-sized icons.
large	Use large icons.
huge	Use even larger icons.
giant	Use very big icons.

The exact dimensions in pixels of the various icon sizes depend on the current theme. Common dimensions are giant=48x48, huge=32x32, large=24x24, medium=24x24, small=20x20 and tiny=16x16.

If **'toolbariconsize'** is empty, the global default size as determined by user preferences or the current theme is used.

**'ttybuiltin'** **'tbi'** boolean (default on)  
global  
**'nottybuiltin'** **'notbi'**

When on, the builtin termcaps are searched before the external ones.

When off the builtin termcaps are searched after the external ones.

When this option is changed, you should set the **'term'** option next for the change to take effect, for example:

```
:set notbi term=$TERM
```

See also [termcap](#) .

Rationale: The default for this option is "on", because the builtin termcap entries are generally better (many systems contain faulty xterm entries...).

**'ttyfast' 'tf'** 'ttyfast' 'tf' 'nottyfast' 'notf'  
boolean (default on)  
global

Indicates a fast terminal connection. More characters will be sent to the screen for redrawing, instead of using insert/delete line commands. Improves smoothness of redrawing when there are multiple windows and the terminal does not support a scrolling region. Also enables the extra writing of characters at the end of each screen line for lines that wrap. This helps when using copy/paste with the mouse in an xterm and other terminals.

The default used to be set only for some terminal names, but these days nearly all terminals are fast, therefore the default is now "on". If you have a slow connection you may want to set this option off, e.g. depending on the host name:

```
if hostname() =~ 'faraway'
 set nottyfast
endif
```

**'ttymouse' 'ttym'** 'ttymouse' 'ttym'  
string (default depends on **'term'**)  
global  
{only in Unix and VMS, doesn't work in the GUI; not available when compiled without **+mouse** }

Name of the terminal type for which mouse codes are to be recognized. Currently these strings are valid:

xterm	<span style="float: right;">xterm-mouse</span> xterm-like mouse handling. The mouse generates " <b>&lt;Esc&gt;</b> [Mscr", where "scr" is three bytes: "s" = button state "c" = column plus 33 "r" = row plus 33 This only works up to 223 columns! See "dec", "urxvt", and "sgr" for solutions.
xterm2	Works like "xterm", but with the xterm reporting the mouse position while the mouse is dragged. This works much faster and more precise. Your xterm must at least at patchlevel 88 / XFree 3.3.3 for this to work. See below for how Vim detects this automatically.
netterm	<span style="float: right;">netterm-mouse</span> NetTerm mouse handling. A left mouse click generates " <b>&lt;Esc&gt;</b> }r,c <b>&lt;CR&gt;</b> ", where "r,c" are two decimal numbers for the row and column. No other mouse events are supported.
dec	<span style="float: right;">dec-mouse</span> DEC terminal mouse handling. The mouse generates a rather complex sequence, starting with " <b>&lt;Esc&gt;</b> ". This is also available for an Xterm, if it was

	configured with "--enable-dec-locator".	
		<code>jsbterm-mouse</code>
<code>jsbterm</code>	JSB term mouse handling.	
		<code>pterm-mouse</code>
<code>pterm</code>	QNX pterm mouse handling.	
		<code>urxvt-mouse</code>
<code>urxvt</code>	Mouse handling for the urxvt (rxvt-unicode) terminal. The mouse works only if the terminal supports this encoding style, but it does not have 223 columns limit unlike "xterm" or "xterm2".	
		<code>sgr-mouse</code>
<code>sgr</code>	Mouse handling for the terminal that emits SGR-styled mouse reporting. The mouse works even in columns beyond 223. This option is backward compatible with "xterm2" because it can also decode "xterm2" style mouse codes.	

The mouse handling must be enabled at compile time `+mouse_xterm +mouse_dec +mouse_netterm +mouse_jsbterm +mouse_urxvt +mouse_sgr`.

Only "xterm"(2) is really recognized. NetTerm mouse codes are always recognized, if enabled at compile time. DEC terminal mouse codes are recognized if enabled at compile time, and `'ttymouse'` is not "xterm", "xterm2", "urxvt" or "sgr" (because dec mouse codes conflict with them).

This option is automatically set to "xterm", when the `'term'` option is set to a name that starts with "xterm", "mlterm", "screen", "tmux", "st" (full match only), "st-" or "stterm", and `'ttymouse'` is not set already.

If the terminfo/termcap entry "XM" exists and the first number is "1006" then `'ttymouse'` will be set to "sgr". This works for many modern terminals.

Additionally, if vim is compiled with the `+termresponse` feature and `t_RV` is set to the escape sequence to request the xterm version number, more intelligent detection is done.

The "xterm2" value will be set if the xterm version is reported to be from 95 to 276. The "sgr" value will be set if Vim detects Mac Terminal.app, iTerm2 or mintty, and when the xterm version is 277 or higher.

If you do not want `'ttymouse'` to be set to "xterm2" or "sgr" automatically, set `t_RV` to an empty string:

```
:set t_RV=
```

		<code>'ttyscroll'</code>	<code>'tsl'</code>
<code>'ttyscroll'</code>	<code>'tsl'</code>	number (default 999)	
		global	

Maximum number of lines to scroll the screen. If there are more lines to scroll the window is redrawn. For terminals where scrolling is very slow and redrawing is not slow this can be set to a small number, e.g., 3, to speed up displaying.

		<code>'ttytype'</code>	<code>'tty'</code>
<code>'ttytype'</code>	<code>'tty'</code>	string (default from \$TERM)	
		global	

Alias for **'term'**, see above.

**'undodir' 'udir'** **'undodir' 'udir'**  
string (default ".")  
global  
{only when compiled with the |+persistent\_undo| feature}  
List of directory names for undo files, separated with commas.  
See **'backupdir'** for details of the format.  
"." means using the directory of the file. The undo file name for "file.txt" is ".file.txt.un~".  
For other directories the file name is the full path of the edited file, with path separators replaced with "%".  
When writing: The first directory that exists is used. "." always works, no directories after "." will be used for writing.  
When reading all entries are tried to find an undo file. The first undo file that exists is used. When it cannot be read an error is given, no further entry is used.  
See [undo-persistence](#) .  
This option cannot be set from a [modeline](#) or in the [sandbox](#) , for security reasons.

**'undofile' 'udf'** **'undofile' 'noundofile' 'udf' 'noundf'**  
boolean (default off)  
local to buffer  
{only when compiled with the |+persistent\_undo| feature}  
When on, Vim automatically saves undo history to an undo file when writing a buffer to a file, and restores undo history from the same file on buffer read.  
The directory where the undo file is stored is specified by **'undodir'**.  
For more information about this feature see [undo-persistence](#) .  
The undo file is not read when **'undoreload'** causes the buffer from before a reload to be saved for undo.  
When **'undofile'** is turned off the undo file is NOT deleted.  
**NOTE:** This option is reset when **'compatible'** is set.

**'undolevels' 'ul'** **'undolevels' 'ul'**  
number (default 100, 1000 for Unix, VMS and Win32)  
global or local to buffer [global-local](#)  
Maximum number of changes that can be undone. Since undo information is kept in memory, higher numbers will cause more memory to be used. Nevertheless, a single change can already use a large amount of memory. Set to 0 for Vi compatibility: One level of undo and "u" undoes itself:

`set ul=0`

But you can also get Vi compatibility by including the 'u' flag in **'cptions'**, and still be able to use **CTRL-R** to repeat undo.

Also see [undo-two-ways](#) .

Set to -1 for no undo at all. You might want to do this only for the current buffer:

`setlocal ul=-1`

This helps when you run out of memory for a single change.

The local value is set to -123456 when the global value is to be used.

Also see [clear-undo](#) .

**'undoreload' 'ur'**                    number (default 10000)                    **'undoreload'**    **'ur'**  
                                          global  
Save the whole buffer for undo when reloading it. This applies to the ":e!" command and reloading for when the buffer changed outside of Vim. [FileChangedShell](#)  
The save only happens when this option is negative or when the number of lines is smaller than the value of this option.  
Set this option to zero to disable undo for a reload.

When saving undo for a reload, any undo file is not read.

**Note** that this causes the whole buffer to be stored in memory. Set this option to a lower value if you run out of memory.

**'updatecount' 'uc'**                    number (default: 200)                    **'updatecount'**    **'uc'**  
                                          global  
After typing this many characters the swap file will be written to disk. When zero, no swap file will be created at all (see chapter on recovery [crash-recovery](#) ). **'updatecount'** is set to zero by starting Vim with the "-n" option, see [startup](#) . When editing in readonly mode this option will be initialized to 10000.  
The swapfile can be disabled per buffer with **'swapfile'** .  
When **'updatecount'** is set from zero to non-zero, swap files are created for all buffers that have **'swapfile'** set. When **'updatecount'** is set to zero, existing swap files are not deleted.  
Also see **'swapsync'** .  
This option has no meaning in buffers where **'buftype'** is "nofile" or "nowrite".

**'updatetime' 'ut'**                    number (default 4000)                    **'updatetime'**    **'ut'**  
                                          global  
If this many milliseconds nothing is typed the swap file will be written to disk (see [crash-recovery](#) ). Also used for the [CursorHold](#) autocommand event.

**'varsofttabstop' 'vsts'** string (default "")                    **'varsofttabstop'**    **'vsts'**  
                                          local to buffer  
                                          {only available when compiled with the [+vartabs](#)  
                                          feature}  
A list of the number of spaces that a <Tab> counts for while editing, such as inserting a <Tab> or using <BS>. It "feels" like variable-width <Tab>s are being inserted, while in fact a mixture of spaces and <Tab>s is used. Tab widths are separated with commas, with the final value applying to all subsequent tabs.

For example, when editing assembly language files where statements start in the 9th column and comments in the 41st, it may be useful to use the following:

```
:set varsofttabstop=8,32,8
```

This will set soft tabstops with 8 and 8 + 32 spaces, and 8 more for every column thereafter.

Note that the value of `'softtabstop'` will be ignored while `'varsofttabstop'` is set.

```
'varsofttabstop' 'vts' string (default "")
 local to buffer
 {only available when compiled with the +vartabs
 feature}
```

A list of the number of spaces that a `<Tab>` in the file counts for, separated by commas. Each value corresponds to one tab, with the final value applying to all subsequent tabs. For example:

```
:set vartabstop=4,20,10,8
```

This will make the first tab 4 spaces wide, the second 20 spaces, the third 10 spaces, and all following tabs 8 spaces.

Note that the value of `'tabstop'` will be ignored while `'vartabstop'` is set.

```
'vartabstop' 'vts' string (default "")
 local to buffer
 {only available when compiled with the +vartabs
 feature}
```

When bigger than zero, Vim will give messages about what it is doing. Currently, these messages are given:

```
>= 1 When the viminfo file is read or written.
>= 2 When a file is ":source"ed.
>= 4 Shell commands.
>= 5 Every searched tags file and include file.
>= 8 Files for which a group of autocommands is executed.
>= 9 Every executed autocommand.
>= 11 Finding items in a path
>= 12 Every executed function.
>= 13 When an exception is thrown, caught, finished, or discarded.
>= 14 Anything pending in a ":finally" clause.
>= 15 Every executed Ex command from a script (truncated at 200
 characters).
>= 16 Every executed Ex command.
```

This option can also be set with the `"-V"` argument. See `-V`. This option is also set by the `:verbose` command.

When the `'verbosefile'` option is set then the verbose messages are not displayed.

```
'verbosefile' 'vfile' string (default empty)
 global
```

When not empty all messages are written in a file with this name. When the file exists messages are appended.

Writing to the file ends when Vim exits or when `'verbosefile'` is made empty. Writes are buffered, thus may not show up for some time.

Setting **'verbosefile'** to a new value is like making it empty first. The difference with `:redir` is that verbose messages are not displayed when **'verbosefile'** is set. This option cannot be set from a `modeline` or in the `sandbox`, for security reasons.

```

'viewdir' 'vdir' 'viewdir' 'vdir'
 string (default for Amiga: "home:vimfiles/view",
 for Win32: "$HOME/vimfiles/view",
 for Unix: "$HOME/.vim/view" or
 "$XDG_CONFIG_HOME/vim/view"
 for VMS: "sys$login:vimfiles/view")
 global
 {not available when compiled without the +mksession
 feature}

```

Name of the directory where to store files for `:mkview`. For `$XDG_CONFIG_HOME` see `xdg-base-dir`. This option cannot be set from a `modeline` or in the `sandbox`, for security reasons.

```

'viewoptions' 'vop' 'viewoptions' 'vop'
 string (default: "folds,options,cursor,curdir")
 global
 {not available when compiled without the +mksession
 feature}

```

Changes the effect of the `:mkview` command. It is a comma-separated list of words. Each word enables saving and restoring something:

<b>word</b>	<b>save and restore</b>
cursor	cursor position in file and in window
folds	manually created folds, opened/closed folds and local fold options
options	options and mappings local to a window or buffer (not global values for local options)
localoptions	same as "options"
slash	backslashes in file names replaced with forward slashes
unix	with Unix end-of-line format (single <code>&lt;NL&gt;</code> ), even when on MS-Windows
curdir	the window-local directory, if set with <code>:lcd`</code>

"slash" and "unix" are useful on MS-Windows when sharing view files with Unix. The Unix version of Vim cannot source dos format scripts, but the MS-Windows version of Vim can source unix format scripts.

```

'vminfo' 'vi' 'vminfo' 'vi' E526 E527 E528
 string (Vi default: "", Vim default for
 MS-Windows: '100,<50,s10,h,rA:,rB:',
 for Amiga: '100,<50,s10,h,rdf0:,rdf1:,rdf2:'
 for others: '100,<50,s10,h)
 global
 {not available when compiled without the +vminfo
 feature}

```

When non-empty, the viminfo file is read upon startup and written when exiting Vim (see `vminfo-file`). Except when **'vminfofile'** is

"NONE".

The string should be a comma-separated list of parameters, each consisting of a single character identifying the particular parameter, followed by a number or string which specifies the value of that parameter. If a particular character is left out, then the default value is used for that parameter. The following is a list of the identifying characters and the effect of their value.

CHAR VALUE

- ! viminfo-!  
When included, save and restore global variables that start with an uppercase letter, and don't contain a lowercase letter. Thus "KEEPTHIS and "K\_L\_M" are stored, but "KeepThis" and "\_K\_L\_M" are not. Nested List and Dict items may not be read back correctly, you end up with an empty item.
- " viminfo-quote  
Maximum number of lines saved for each register. Old name of the '<' item, with the disadvantage that you need to put a backslash before the ", otherwise it will be recognized as the start of a comment!
- % viminfo-%  
When included, save and restore the buffer list. If Vim is started with a file name argument, the buffer list is not restored. If Vim is started without a file name argument, the buffer list is restored from the viminfo file. Quickfix ('buftype'), unlisted ('buflisted'), unnamed and buffers on removable media ( viminfo-r ) are not saved. When followed by a number, the number specifies the maximum number of buffers that are stored. Without a number all buffers are stored.
- ' viminfo-'  
Maximum number of previously edited files for which the marks are remembered. This parameter must always be included when 'viminfo' is non-empty. Including this item also means that the jumplist and the changelist are stored in the viminfo file.
- / viminfo-/  
Maximum number of items in the search pattern history to be saved. If non-zero, then the previous search and substitute patterns are also saved. When not included, the value of 'history' is used.
- : viminfo-:  
Maximum number of items in the command-line history to be saved. When not included, the value of 'history' is used.
- < viminfo-<  
Maximum number of lines saved for each register. If zero then registers are not saved. When not included, all lines are saved. ''' is the old name for this item. Also see the 's' item below: limit specified in Kbyte.
- @ viminfo-@  
Maximum number of items in the input-line history to be saved. When not included, the value of 'history' is used.
- c viminfo-c  
When included, convert the text in the viminfo file from the 'encoding' used when writing the file to the current

**'encoding'**. See [viminfo-encoding](#) .

- viminfo-f**
- f Whether file marks need to be stored. If zero, file marks ('0 to '9, 'A to 'Z) are not stored. When not present or when non-zero, they are all stored. '0 is used for the current cursor position (when exiting or when doing ":wviminfo").
- viminfo-h**
- h Disable the effect of **'hlsearch'** when loading the viminfo file. When not included, it depends on whether ":nohlsearch" has been used since the last search command.
- viminfo-n**
- n Name of the viminfo file. The name must immediately follow the 'n'. Must be at the end of the option! If the **'viminfofile'** option is set, that file name overrides the one given here with **'viminfo'**. Environment variables are expanded when opening the file, not when setting the option.
- viminfo-r**
- r Removable media. The argument is a string (up to the next ','). This parameter can be given several times. Each specifies the start of a path for which no marks will be stored. This is to avoid removable media. For MS-Windows you could use "ra:,rb:", for Amiga "rdf0:,rdf1:,rdf2:". You can also use it for temp files, e.g., for Unix: "r/tmp". Case is ignored. Maximum length of each 'r' argument is 50 characters.
- viminfo-s**
- s Maximum size of an item in Kbyte. If zero then registers are not saved. Currently only applies to registers. The default "s10" will exclude registers with more than 10 Kbyte of text. Also see the '<' item above: line count limit.

Example:

```
:set viminfo='50,<1000,s100,:0,n~/vim/viminfo
```

- '50 Marks will be remembered for the last 50 files you edited.
- <1000 Contents of registers (up to 1000 lines each) will be remembered.
- s100 Registers with more than 100 Kbyte text are skipped.
- :0 Command-line history will not be saved.
- n~/vim/viminfo The name of the file to use is "~/vim/viminfo".
- no / Since '/' is not specified, the default will be used, that is, save all of the search history, and also the previous search and substitute patterns.
- no % The buffer list will not be saved nor read back.
- no h **'hlsearch'** highlighting will be restored.

When setting **'viminfo'** from an empty value you can use `:rviminfo` to load the contents of the file, this is not done automatically.

This option cannot be set from a [modeline](#) or in the [sandbox](#) , for security reasons.

**NOTE:** This option is set to the Vim default value when **'compatible'** is reset.

**'viminfofile' 'vif'** 'viminfofile' 'vif'  
 string (default: "")  
 global  
 {not available when compiled without the `+viminfo`  
 feature}

When non-empty, overrides the file name used for viminfo.  
 When equal to "NONE" no viminfo file will be read or written.  
 This option can be set with the `-i` command line flag. The `--clean`  
 command line flag sets it to "NONE".  
 This option cannot be set from a `modeline` or in the `sandbox`, for  
 security reasons.

**'virtualedit' 've'** 'virtualedit' 've'  
 string (default: "")  
 global or local to window `global-local`

A comma-separated list of these words:  
 block Allow virtual editing in Visual block mode.  
 insert Allow virtual editing in Insert mode.  
 all Allow virtual editing in all modes.  
 onemore Allow the cursor to move just past the end of the line  
 none When used as the local value, do not allow virtual  
 editing even when the global value is set. When used  
 as the global value, "none" is the same as "".  
 NONE Alternative spelling of "none".

Virtual editing means that the cursor can be positioned where there is  
 no actual character. This can be halfway into a tab or beyond the end  
 of the line. Useful for selecting a rectangle in Visual mode and  
 editing a table.

"onemore" is not the same, it will only allow moving the cursor just  
 after the last character of the line. This makes some commands more  
 consistent. Previously the cursor was always past the end of the line  
 if the line was empty. But it is far from Vi compatible. It may also  
 break some plugins or Vim scripts. For example because `l` can move  
 the cursor after the last character. Use with care!

Using the ``$`` command will move to the last character in the line, not  
 past it. This may actually move the cursor to the left!

The ``g$`` command will move to the end of the screen line.

It doesn't make sense to combine "all" with "onemore", but you will  
 not get a warning for it.

When combined with other words, "none" is ignored.

**NOTE:** This option is set to "" when **'compatible'** is set.

**'visualbell' 'vb'** 'visualbell' 'vb' 'novisualbell' 'novb' beep  
 boolean (default off)  
 global

Use a visual bell instead of beeping. The terminal code to display the  
 visual bell is given with `'t_vb'`. When no beep or flash is wanted,  
 use:

```
:set vb t_vb=
```

If you want a short flash, you can use this on many terminals:

```
:set vb t_vb=?[?5h$<100>?[?5l
```

Here `$<100>` specifies the time, you can use a smaller or bigger value

to get a shorter or longer flash.

**Note:** Vim will limit the bell to once per half a second. This avoids having to wait for the flashing to finish when there are lots of bells, e.g. on key repeat. This also happens without **'visualbell'** set.

In the GUI, **'t\_vb'** defaults to "<Esc>|f", which inverts the display for 20 msec. If you want to use a different time, use "<Esc>|40f", where 40 is the time in msec.

**Note:** When the GUI starts, **'t\_vb'** is reset to its default value. You might want to set it again in your `gvimrc`.

Does not work on the Amiga, you always get a screen flash.  
Also see **'errorbells'**.

**'warn'** **'warn'** **'nowarn'**  
boolean (default on)  
global  
Give a warning message when a shell command is used while the buffer has been changed.

**'weirdinvert'** **'wiv'** **'weirdinvert'** **'wiv'** **'noweirdinvert'** **'nowiv'**  
boolean (default off)  
global  
This option has the same effect as the **'t\_xs'** terminal option. It is provided for backwards compatibility with version 4.x. Setting **'weirdinvert'** has the effect of making **'t\_xs'** non-empty, and vice versa. Has no effect when the GUI is running.

**'whichwrap'** **'ww'** **'whichwrap'** **'ww'**  
string (Vim default: "b,s", Vi default: "")  
global  
Allow specified keys that move the cursor left/right to move to the previous/next line when the cursor is on the first/last character in the line. Concatenate characters to allow this for these keys:

char	key	mode
b	<BS>	Normal and Visual
s	<Space>	Normal and Visual
h	"h"	Normal and Visual (not recommended)
l	"l"	Normal and Visual (not recommended)
<	<Left>	Normal and Visual
>	<Right>	Normal and Visual
~	"~"	Normal
[	<Left>	Insert and Replace
]	<Right>	Insert and Replace

For example:

```
:set ww=<,>,[,]
```

allows wrap only when cursor keys are used.

When the movement keys are used in combination with a delete or change operator, the `<EOL>` also counts for a character. This makes "3h" different from "3dh" when the cursor crosses the end of a line. This is also true for "x" and "X", because they do the same as "dl" and

"dh". If you use this, you may also want to use the mapping `":map <BS> X"` to make backspace delete the character in front of the cursor.

When 'l' is included and it is used after an operator at the end of a line (not an empty line) then it will not move to the next line. This makes "dl", "cl", "yl" etc. work normally.

**NOTE:** This option is set to the Vi default value when **'compatible'** is set and to the Vim default value when **'compatible'** is reset.

**'wildchar'** **'wc'** 'wildchar' 'wc'  
number (Vim default: <Tab>, Vi default: **CTRL-E**)  
global

Character you have to type to start wildcard expansion in the command-line, as specified with **'wildmode'**.

More info here: [cmdline-completion](#) .

The character is not recognized when used inside a macro. See **'wildcharm'** for that.

Some keys will not work, such as **CTRL-C**, <CR> and Enter.

<Esc> can be used, but hitting it twice in a row will still exit command-line as a failsafe measure.

Although **'wc'** is a number option, it can be specified as a number, a single character, a [key-notation](#) (e.g. <Up>, <C-F>) or a letter preceded with a caret (e.g. ``^F`` is **CTRL-F**):

```
:set wc=27
:set wc=X
:set wc=^I
:set wc=<Tab>
```

**NOTE:** This option is set to the Vi default value when **'compatible'** is set and to the Vim default value when **'compatible'** is reset.

**'wildcharm'** **'wcm'** 'wildcharm' 'wcm'  
number (default: none (0))  
global

**'wildcharm'** works exactly like **'wildchar'**, except that it is recognized when used inside a macro. You can find "spare" command-line keys suitable for this option by looking at [ex-edit-index](#) . Normally you'll never actually type **'wildcharm'**, just use it in mappings that automatically invoke completion mode, e.g.:

```
:set wcm=<C-Z>
:cnoemap ss so $vim/sessions/*.vim<C-Z>
```

Then after typing `:ss` you can use **CTRL-P** & **CTRL-N**.

**'wildignore'** **'wig'** 'wildignore' 'wig'  
string (default "")  
global

A list of file patterns. A file that matches with one of these patterns is ignored when expanding [wildcards](#) , completing file or directory names, and influences the result of [expand\(\)](#) , [glob\(\)](#) and [globpath\(\)](#) unless a flag is passed to disable this.

The pattern is used like with `:autocmd` , see [autocmd-patterns](#) .

Also see **'suffixes'**.

Example:

```
:set wildignore=*.o,*.obj
```

The use of `:set+=` and `:set-=` is preferred when adding or removing

a pattern from the list. This avoids problems when a future version uses another default.

**'wildignorecase'** **'wic'** **'nowildignorecase'** **'nowic'**  
boolean (default off)  
global

When set case is ignored when completing file names and directories. Has no effect when **'fileignorecase'** is set. Does not apply when the shell is used to expand wildcards, which happens when there are special characters.

**'wildmenu'** **'wmnu'** **'wildmenu'** **'wmnu'** **'nowildmenu'** **'nowmnu'**  
boolean (default on)  
global

When **'wildmenu'** is on, command-line completion operates in an enhanced mode. On pressing **'wildchar'** (usually `<Tab>`) to invoke completion, the possible matches are shown.

When **'wildoptions'** contains "pum", then the completion matches are shown in a popup menu. Otherwise they are displayed just above the command line, with the first match highlighted (overwriting the status line, if there is one).

Keys that show the previous/next match, such as `<Tab>` or **CTRL-P/CTRL-N**, cause the highlight to move to the appropriate match.

When **'wildmode'** is used, "wildmenu" mode is used where "full" is specified. "longest" and "list" do not start "wildmenu" mode.

You can check the current mode with `wildmenumode()`.

If there are more matches than can fit in the line, a ">" is shown on the right and/or a "<" is shown on the left. The status line scrolls as needed.

The "wildmenu" mode is abandoned when a key is hit that is not used for selecting a completion.

While the "wildmenu" is active, the following keys have special meanings:

- CTRL-P** - go to the previous entry
- CTRL-N** - go to the next entry
- <CR>** - in menu completion, when the cursor is just after a dot: move into a submenu.
- CTRL-E** - end completion, go back to what was there before selecting a match.
- CTRL-Y** - accept the currently selected match and stop completion.

When not using the popup menu for command line completion, the following keys have special meanings:

- <Left>** **<Right>** - select previous/next match (like **CTRL-P/CTRL-N**)
- <Up>** - in filename/menu name completion: move up into parent directory or parent menu.
- <Down>** - in filename/menu name completion: move into a subdirectory or submenu.

When using the popup menu for command line completion, the following keys have special meanings:

- <Up>** **<Down>** - select previous/next match (like **CTRL-P/CTRL-N**)
- <PageUp>** - select a match several entries back

- <PageDown> - select a match several entries further
- <Left> - in filename/menu name completion: move up into parent directory or parent menu.
- <Right> - in filename/menu name completion: move into a subdirectory or submenu.

This makes the menus accessible from the console `console-menus` .

If you prefer the <Left> and <Right> keys to move the cursor instead of selecting a different match, use this:

```
:cnoremap <Left> <Space><BS><Left>
:cnoremap <Right> <Space><BS><Right>
```

The "WildMenu" highlighting is used for displaying the current match `hl-WildMenu` .

```
'wildmode' 'wim' 'wildmode' 'wim'
string (Vim default: "full")
global
```

Completion mode that is used for the character specified with `'wildchar'`. It is a comma-separated list of up to four parts. Each part specifies what to do for each consecutive use of `'wildchar'`. The first part specifies the behavior for the first use of `'wildchar'`, The second part for the second use, etc.

Each part consists of a colon separated list consisting of the following possible values:

```
"" Complete only the first match.
"full" Complete the next full match. After the last match,
 the original string is used and then the first match
 again. Will also start 'wildmenu' if it is enabled.
"longest" Complete till longest common string. If this doesn't
 result in a longer string, use the next part.
"list" When more than one match, list all matches.
"lastused" When completing buffer names and more than one buffer
 matches, sort buffers by time last used (other than
 the current buffer).
"noselect" Do not pre-select first menu item and start 'wildmenu'
 if it is enabled.
```

When there is only a single match, it is fully completed in all cases except when "noselect" is present.

Examples of useful colon-separated values:

```
"longest:full" Like "longest", but also start 'wildmenu' if it is
 enabled. Will not complete to the next full match.
"list:full" When more than one match, list all matches and
 complete first match.
"list:longest" When more than one match, list all matches and
 complete till longest common string.
"list:lastused" When more than one buffer matches, list all matches
 and sort buffers by time last used (other than the
 current buffer).
```

Examples:

```

: set wildmode=full
Complete first full match, next match, etc. (the default)
: set wildmode=longest,full
Complete longest common string, then each full match
: set wildmode=list:full
List all matches and complete each full match
: set wildmode=list,full
List all matches without completing, then each full match
: set wildmode=longest,list
Complete longest common string, then list alternatives
: set wildmode=noselect:full
Display 'wildmenu' without completing, then each full match
: set wildmode=noselect:lastused,full
Same as above, but sort buffers by time last used.
More info here: cmdline-completion .

```

```

'wildoptions' 'wop' string (default "")
 global
 'wildoptions' 'wop'
A list of words that change how cmdline-completion is done.
The following values are supported:
fuzzy Use fuzzy-matching to find completion matches. When
 this value is specified, wildcard expansion will not
 be used for completion. The matches will be sorted by
 the "best match" rather than alphabetically sorted.
 This will find more matches than the wildcard
 expansion. Currently fuzzy matching based completion
 is not supported for file and directory names and
 instead wildcard expansion is used.
pum Display the completion matches using the popup menu
 in the same style as the ins-completion-menu .
tagfile When using CTRL-D to list matching tags, the kind of
 tag and the file of the tag is listed. Only one match
 is displayed per line. Often used tag kinds are:
 d #define
 f function

```

```

'winaltkeys' 'wak' string (default "menu")
 global
 'winaltkeys' 'wak'
 {only used in Win32, Motif, GTK and Photon GUI}
Some GUI versions allow the access to menu entries by using the ALT
key in combination with a character that appears underlined in the
menu. This conflicts with the use of the ALT key for mappings and
entering special characters. This option tells what to do:
no Don't use ALT keys for menus. ALT key combinations can be
 mapped, but there is no automatic handling. This can then be
 done with the :simalt command.
yes ALT key handling is done by the windowing system. ALT key
 combinations cannot be mapped.
menu Using ALT in combination with a character that is a menu
 shortcut key, will be handled by the windowing system. Other
 keys can be mapped.
If the menu is disabled by excluding 'm' from 'guioptions', the ALT

```

key is never used for the menu.  
This option is not used for <F10>; on Win32 and with GTK <F10> will select the menu, unless it has been mapped.

**'wincolor'** **'wcr'** string (default empty) 'wincolor' 'wcr'  
local to window  
Highlight group name to use for this window instead of the Normal color `hl-Normal` .

**'window'** **'wi'** number (default screen height - 1) 'window' 'wi'  
global  
Window height used for `CTRL-F` and `CTRL-B` when there is only one window and the value is smaller than **'lines'** minus one. The screen will scroll **'window'** minus two lines, with a minimum of one. When **'window'** is equal to **'lines'** minus one `CTRL-F` and `CTRL-B` scroll in a much smarter way, taking care of wrapping lines. When resizing the Vim window, and the value is smaller than 1 or more than or equal to **'lines'** it will be set to **'lines'** minus 1.  
**Note:** Do not confuse this with the height of the Vim window, use **'lines'** for that.

**'winfixbuf'** **'wfb'** boolean (default off) 'winfixbuf'  
local to window  
If enabled, the window and the buffer it is displaying are paired. For example, attempting to change the buffer with `:edit` will fail. Other commands which change a window's buffer such as `:cnext` will also skip any window with **'winfixbuf'** enabled. However if an Ex command has a `!"` modifier, it can force switching buffers.

**'winfixheight'** **'wfh'** boolean (default off) 'winfixheight' 'wfh' 'nowinfixheight' 'nowfh'  
local to window `local-noglobal`  
Keep the window height when windows are opened or closed and **'equalalways'** is set. Also for `CTRL-W_=` . Set by default for the `preview-window` and `quickfix-window` .  
The height may be changed anyway when running out of room.

**'winfixwidth'** **'wfw'** boolean (default off) 'winfixwidth' 'wfw' 'nowinfixwidth' 'nowfw'  
local to window `local-noglobal`  
Keep the window width when windows are opened or closed and **'equalalways'** is set. Also for `CTRL-W_=` .  
The width may be changed anyway when running out of room.

**'winheight'** **'wh'** number (default 1) 'winheight' 'wh' E591  
global  
Minimal number of lines for the current window. This is not a hard minimum, Vim will use fewer lines if there is not enough room. If the focus goes to a window that is smaller, its size is increased, at the cost of the height of other windows.

Set **'winheight'** to a small number for normal editing.  
 Set it to 999 to make the current window fill most of the screen.  
 Other windows will be only **'winminheight'** high. This has the drawback  
 that `":all"` will create only two windows. To avoid `"vim -o 1 2 3 4"`  
 to create only two windows, set the option after startup is done,  
 using the `VimEnter` event:

```
au VimEnter * set winheight=999
```

Minimum value is 1.

The height is not adjusted after one of the commands that change the  
 height of the current window.

**'winheight'** applies to the current window. Use **'winminheight'** to set  
 the minimal height for other windows.

**'winminheight'** **'wmh'**                    **'winminheight'**    **'wmh'**  
                                          number (default 1)  
                                          global

The minimal height of a window, when it's not the current window.

This is a hard minimum, windows will never become smaller.

When set to zero, windows may be "squashed" to zero lines (i.e. just a  
 status bar) if necessary. They will return to at least one line when  
 they become active (since the cursor has to have somewhere to go.)

Use **'winheight'** to set the minimal height of the current window.

This option is only checked when making a window smaller. Don't use a  
 large number, it will cause errors when opening more than a few  
 windows. A value of 0 to 3 is reasonable.

**'winminwidth'** **'wmw'**                    **'winminwidth'**    **'wmw'**  
                                          number (default 1)  
                                          global

The minimal width of a window, when it's not the current window.

This is a hard minimum, windows will never become smaller.

When set to zero, windows may be "squashed" to zero columns (i.e. just  
 a vertical separator) if necessary. They will return to at least one  
 line when they become active (since the cursor has to have somewhere  
 to go.)

Use **'winwidth'** to set the minimal width of the current window.

This option is only checked when making a window smaller. Don't use a  
 large number, it will cause errors when opening more than a few  
 windows. A value of 0 to 12 is reasonable.

**'winptydll'**                                            **'winptydll'**  
                                          string (default "winpty32.dll" or "winpty64.dll")  
                                          global  
                                          {only available when compiled with the `terminal`  
                                          feature on MS-Windows}

Specifies the name of the winpty shared library, used for the

`:terminal` command. The default depends on whether Vim was built as a  
 32-bit or 64-bit executable. If not found, "winpty.dll" is tried as  
 a fallback.

Environment variables are expanded `:set_env`.

This option cannot be set from a `modeline` or in the `sandbox`, for  
 security reasons.

**'winwidth'**    **'wiw'**    E592

**'winwidth'** **'wiw'**            number (default 20)  
                                  global

Minimal number of columns for the current window. This is not a hard minimum, Vim will use fewer columns if there is not enough room. If the current window is smaller, its size is increased, at the cost of the width of other windows. Set it to 999 to make the current window always fill the screen. Set it to a small number for normal editing. The width is not adjusted after one of the commands to change the width of the current window.

**'winwidth'** applies to the current window. Use **'winminwidth'** to set the minimal width for other windows.

**'wrap'**                            boolean (default on)            **'wrap'**    **'nowrap'**  
                                  local to window

This option changes how text is displayed. It doesn't change the text in the buffer, see **'textwidth'** for that.

When on, lines longer than the width of the window will wrap and displaying continues on the next line. When off lines will not wrap and only part of long lines will be displayed. When the cursor is moved to a part that is not shown, the screen will scroll horizontally.

The line will be broken in the middle of a word if necessary. See **'linebreak'** to get the break at a word boundary.

To make scrolling horizontally a bit more useful, try this:

```
:set sidescroll=5
:set listchars+=precedes:<,extends:>
```

See **'sidescroll'**, **'listchars'** and `wrap-off` .

This option can't be set from a `modeline` when the **'diff'** option is on.

**'wrapmargin'** **'wm'**            number (default 0)            **'wrapmargin'**    **'wm'**  
                                  local to buffer

Number of characters from the right window border where wrapping starts. When typing text beyond this limit, an `<EOL>` will be inserted and inserting continues on the next line.

Options that add a margin, such as **'number'** and **'foldcolumn'**, cause the text width to be further reduced. This is Vi compatible.

When **'textwidth'** is non-zero, this option is not used.

This option is set to 0 when **'paste'** is set and restored when **'paste'** is reset.

See also **'formatoptions'** and `ins-textwidth` .

**'wrapscan'** **'ws'**            boolean (default on)            **'wrapscan'**    **'ws'**    **'nowrapscan'**    **'nows'**  
                                  global                                                            E384    E385

Searches wrap around the end of the file. Also applies to `]s` and `[s` , searching for spelling mistakes.

**'write'**                            boolean (default on)            **'write'**    **'nowrite'**  
                                  global

Allows writing files. When not set, writing a file is not allowed.

Can be used for a view-only mode, where modifications to the text are still allowed. Can be reset with the `-m` or `-M` command line argument. Filtering text is still possible, even though this requires writing a temporary file.

`'writeany'` `'wa'` `'writeany'` `'wa'` `'nowriteany'` `'nowa'`  
boolean (default off)  
global

Allows writing to any file with no need for `!"` override.

`'writebackup'` `'wb'` `'writebackup'` `'wb'` `'nowritebackup'` `'nowb'`  
boolean (default on with `+writebackup` feature, off otherwise)  
global

Make a backup before overwriting a file. The backup is removed after the file was successfully written, unless the `'backup'` option is also on.

WARNING: Switching this option off means that when Vim fails to write your buffer correctly and then, for whatever reason, Vim exits, you lose both the original file and what you were writing. Only reset this option if your file system is almost full and it makes the write fail (and make sure not to exit Vim until the write was successful). See [backup-table](#) for another explanation.

When the `'backupskip'` pattern matches, a backup is not made anyway. Depending on `'backupcopy'` the backup is a new file or the original file renamed (and a new file is written).

NOTE: This option is set to the default value when `'compatible'` is set.

`'writedelay'` `'wd'` `'writedelay'` `'wd'`  
number (default 0)  
global

The number of milliseconds to wait for each character sent to the screen. When non-zero, characters are sent to the terminal one by one. For debugging purposes.

`'xtermcodes'` `'xtermcodes'` `'noxtermcodes'`  
boolean (default on)  
global

When detecting xterm patchlevel 141 or higher with the `termresponse` mechanism and this option is set, Vim will request the actual terminal key codes and number of colors from the terminal. This takes care of various configuration options of the terminal that cannot be obtained from the `termlib/terminfo` entry, see [xterm-codes](#).

A side effect may be that `t_Co` changes and Vim will redraw the display.

Patterns and search commands

pattern-searches

The very basics can be found in section 03.9 of the user manual. A few more explanations are in chapter 27 [usr\\_27.txt](#) .

=====  
1. Search commands

[search-commands](#)

- |                                            |                                                                                                                                                                                                       |
|--------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>/[pattern][/]&lt;CR&gt;</code>       | Search forward for the <code>[count]</code> 'th occurrence of <code>{pattern}</code> <a href="#">exclusive</a> .                                                                                      |
| <code>/[pattern]/[offset]&lt;CR&gt;</code> | Search forward for the <code>[count]</code> 'th occurrence of <code>{pattern}</code> and go <code>{offset}</code> lines up or down. <a href="#">linewise</a> .                                        |
| <code>/&lt;CR&gt;</code>                   | Search forward for the <code>[count]</code> 'th occurrence of the latest used pattern <code>last-pattern</code> with latest used <code>{offset}</code> .                                              |
| <code>//[offset]&lt;CR&gt;</code>          | Search forward for the <code>[count]</code> 'th occurrence of the latest used pattern <code>last-pattern</code> with new <code>{offset}</code> . If <code>{offset}</code> is empty no offset is used. |
| <code>?[pattern][?]&lt;CR&gt;</code>       | Search backward for the <code>[count]</code> 'th previous occurrence of <code>{pattern}</code> <a href="#">exclusive</a> .                                                                            |
| <code>?[pattern]?[offset]&lt;CR&gt;</code> | Search backward for the <code>[count]</code> 'th previous occurrence of <code>{pattern}</code> and go <code>{offset}</code> lines up or down <a href="#">linewise</a> .                               |
| <code>?&lt;CR&gt;</code>                   | Search backward for the <code>[count]</code> 'th occurrence of the latest used pattern <code>last-pattern</code> with latest used                                                                     |

`{offset} .`

`??{offset}<CR>` Search backward for the `[count]`'th occurrence of the latest used pattern `last-pattern` with new `{offset}` . If `{offset}` is empty no offset is used.

`n` Repeat the latest `"/` or `"?` `n` `[count]` times. If the cursor doesn't move the search is repeated with `count + 1`.  
`last-pattern`

`N` Repeat the latest `"/` or `"?` `N` `[count]` times in opposite direction. `last-pattern`

`*` Search forward for the `[count]`'th occurrence of the word nearest to the cursor. The word used for the search is the first of:

1. the keyword under the cursor `'iskeyword'`
2. the first keyword after the cursor, in the current line
3. the non-blank word under the cursor
4. the first non-blank word after the cursor, in the current line

Only whole keywords are searched for, like with the command `/\<keyword\>`. `exclusive` `'ignorecase'` is used, `'smartcase'` is not.

`#` Same as `"*`, but search backward. The pound sign (character 163) also works. If the `"#` key works as backspace, try using `"stty erase <BS>`" before starting Vim (`<BS>` is **CTRL-H** or a real backspace).

`g*` Like `"*`, but don't put `"\<` and `"\>` around the word. This makes the search also find matches that are not a whole word.

`g#` Like `"#`, but don't put `"\<` and `"\>` around the word. This makes the search also find matches that are not a whole word.

`gd` Goto local Declaration. When the cursor is on a local variable, this command will jump to its declaration. This was made to work for C code, in other languages it may not work well. First Vim searches for the start of the current function, just like `"[`". If it is not found the search stops in line 1. If it is found, Vim goes back

until a blank line is found. From this position Vim searches for the keyword under the cursor, like with "\*", but lines that look like a comment are ignored (see '**comments**' option).

**Note** that this is not guaranteed to work, Vim does not really check the syntax, it only searches for a match with the keyword. If included files also need to be searched use the commands listed in [include-search](#) . After this command **n** searches forward for the next match (not backward).

**gD** **gD**  
Goto global Declaration. When the cursor is on a global variable that is defined in the file, this command will jump to its declaration. This works just like "gd", except that the search for the keyword always starts in line 1.

**lgd** **lgd**  
Like "gd", but ignore matches inside a {} block that ends before the cursor position.

**lgD** **lgD**  
Like "gD", but ignore matches inside a {} block that ends before the cursor position.

**CTRL-C** **CTRL-C**  
Interrupt current (search) command. Use **CTRL-Break** on MS-Windows [dos-CTRL-Break](#) .  
In Normal mode, any pending command is aborted. When Vim was started with output redirected and there are no changed buffers **CTRL-C** exits Vim. That is to help users who use "vim file | grep word" and don't know how to get out (blindly typing :qa<CR> would work).

**:noh[lsearch]** **:noh :nohlsearch**  
Stop the highlighting for the '**hlsearch**' option. It is automatically turned back on when using a search command, or setting the '**hlsearch**' option. This command doesn't work in an autocommand, because the highlighting state is saved and restored when executing autocommands [autocmd-searchpat](#) . Same thing for when invoking a user function.

While typing the search pattern the current match will be shown if the '**incsearch**' option is on. Remember that you still have to finish the search command with <CR> to actually position the cursor at the displayed match. Or use <Esc> to abandon the search.

**nohlsearch-auto**  
All matches for the last used search pattern will be highlighted if you set the '**hlsearch**' option. This can be suspended with the **:nohlsearch** command

or auto suspended with nohlsearch plugin. See [nohlsearch-install](#) .

When **'shortmess'** does not include the "S" flag, Vim will automatically show an index, on which the cursor is. This can look like this:

```
[1/5] Cursor is on first of 5 matches.
[1/>99] Cursor is on first of more than 99 matches.
[>99/>99] Cursor is after 99 match of more than 99 matches.
[?/??] Unknown how many matches exists, generating the
 statistics was aborted because of search timeout.
```

**Note:** the count does not take offset into account.

When no match is found you get the error: **E486** Pattern not found

**Note** that for the `:global` command, when used in legacy script, you get a normal message "Pattern not found", for Vi compatibility.

In **Vim9** script you get E486 for "pattern not found" or **E538** when the pattern matches in every line with `:vglobal`.

For the `:s` command the "e" flag can be used to avoid the error message `:s_flags` .

**search-offset {offset}**

These commands search for the specified pattern. With "/" and "?" an additional offset may be given. There are two types of offsets: line offsets and character offsets.

The offset gives the cursor position relative to the found match:

```
[num] [num] lines downwards, in column 1
+[num] [num] lines downwards, in column 1
-[num] [num] lines upwards, in column 1
e+[num] [num] characters to the right of the end of the match
e-[num] [num] characters to the left of the end of the match
s+[num] [num] characters to the right of the start of the match
s-[num] [num] characters to the left of the start of the match
b+[num] [num] identical to s+[num] above (mnemonic: begin)
b-[num] [num] identical to s-[num] above (mnemonic: begin)
;{pattern} perform another search, see //;
```

If a '-' or '+' is given but [num] is omitted, a count of one will be used. When including an offset with 'e', the search becomes inclusive (the character the cursor lands on is included in operations).

Examples:

<b>pattern</b>	<b>cursor position</b>
/test/+1	one line below "test", in column 1
/test/e	on the last t of "test"
/test/s+2	on the 's' of "test"
/test/b-3	three characters before "test"

If one of these commands is used after an operator, the characters between the cursor position before and after the search is affected. However, if a line offset is given, the whole lines between the two cursor positions are

affected.

An example of how to search for matches with a pattern and change the match with another word:

```
/foo<CR> find "foo"
c//e<CR> change until end of match
bar<Esc> type replacement
//<CR> go to start of next match
c//e<CR> change until end of match
beep<Esc> type another replacement
etc.
```

//; E386

A very special offset is ';' followed by another search command. For example:

```
/test 1//;test
/test.*/+1//;?ing?
```

The first one first finds the next occurrence of "test 1", and then the first occurrence of "test" after that.

This is like executing two search commands after each other, except that:

- It can be used as a single motion command after an operator.
- The direction for a following "n" or "N" command comes from the first search command.
- When an error occurs the cursor is not moved at all.

last-pattern

The last used pattern and offset are remembered. They can be used to repeat the search, possibly in another direction or with another count. Note that two patterns are remembered: One for "normal" search commands and one for the substitute command ":s". Each time an empty pattern is given, the previously used pattern is used. However, if there is no previous search command, a previous substitute pattern is used, if possible.

The 'magic' option sticks with the last used pattern. If you change 'magic', this will not change how the last used pattern will be interpreted.

The 'ignorecase' option does not do this. When 'ignorecase' is changed, it will result in the pattern to match other text.

All matches for the last used search pattern will be highlighted if you set the 'hlsearch' option.

To clear the last used search pattern:

```
:let @/ = ""
```

This will not set the pattern to an empty string, because that would match everywhere. The pattern is really cleared, like when starting Vim.

The search usually skips matches that don't move the cursor. Whether the next match is found at the next character or after the skipped match depends on the 'c' flag in 'coptions'. See cpo-c .

with 'c' flag: "/"..." advances 1 to 3 characters

without 'c' flag: "/"..." advances 1 character

The unpredictability with the 'c' flag is caused by starting the search in the

first column, skipping matches until one is found past the cursor position.

When searching backwards, searching starts at the start of the line, using the 'c' flag in '**cptions**' as described above. Then the last match before the cursor position is used.

In Vi the ":tag" command sets the last search pattern when the tag is searched for. In Vim this is not done, the previous search pattern is still remembered, unless the 't' flag is present in '**cptions**'. The search pattern is always put in the search history.

If the '**wrapscan**' option is on (which is the default), searches wrap around the end of the buffer. If '**wrapscan**' is not set, the backward search stops at the beginning and the forward search stops at the end of the buffer. If '**wrapscan**' is set and the pattern was not found the error message "pattern not found" is given, and the cursor will not be moved. If '**wrapscan**' is not set the message becomes "search hit BOTTOM without match" when searching forward, or "search hit TOP without match" when searching backward. If wrapscan is set and the search wraps around the end of the file the message "search hit TOP, continuing at BOTTOM" or "search hit BOTTOM, continuing at TOP" is given when searching backwards or forwards respectively. This can be switched off by setting the 's' flag in the '**shortmess**' option. The highlight method 'w' is used for this message (default: standout).

#### search-range

You can limit the search command "/" to a certain range of lines by including \>l items. For example, to match the word "limit" below line 199 and above line 300:

```
/\>199l\<300llimit
```

Also see `/\>l` .

Another way is to use the ":substitute" command with the 'c' flag. Example:

```
.,300s/Pattern//gc
```

This command will search from the cursor position until line 300 for "Pattern". At the match, you will be asked to type a character. Type 'q' to stop at this match, type 'n' to find the next match.

The "\*", "#", "g\*" and "g#" commands look for a word near the cursor in this order, the first one that is found is used:

- The keyword currently under the cursor.
- The first keyword to the right of the cursor, in the same line.
- The WORD currently under the cursor.
- The first WORD to the right of the cursor, in the same line.

The keyword may only contain letters and characters in '**iskeyword**'.

The WORD may contain any non-blanks (<Tab>s and/or <Space>s).

**Note** that if you type with ten fingers, the characters are easy to remember: the "#" is under your left hand middle finger (search to the left and up) and the "\*" is under your right hand middle finger (search to the right and down). (this depends on your keyboard layout though).

#### E956

In very rare cases a regular expression is used recursively. This can happen when executing a pattern takes a long time and when checking for messages on channels a callback is invoked that also uses a pattern or an autocommand is

triggered. In most cases this should be fine, but if a pattern is in use when it's used again it fails. Usually this means there is something wrong with the pattern.

=====  
2. The definition of a pattern `search-pattern pattern [pattern]`  
`regular-expression regexp Pattern`  
`E383 E476`

For starters, read chapter 27 of the user manual `usr_27.txt` .

`/bar /\bar /pattern`  
1. A pattern is one or more branches, separated by `"|"`. It matches anything that matches one of the branches. Example: `"foo|beep"` matches `"foo"` and matches `"beep"`. If more than one branch matches, the first one is used.

```
pattern ::= branch
 or branch | branch
 or branch | branch | branch
 etc.
```

`/branch /\&`  
2. A branch is one or more concatenations, separated by `"\&"`. It matches the last concatenation, but only if all the preceding concatenations also match at the same position. Examples:

`"foobeep\&..."` matches `"foo"` in `"foobeep"`.  
`".*Peter\&.*Bob"` matches in a line containing both `"Peter"` and `"Bob"`

```
branch ::= concat
 or concat \& concat
 or concat \& concat \& concat
 etc.
```

`/concat`  
3. A concatenation is one or more pieces, concatenated. It matches a match for the first piece, followed by a match for the second piece, etc. Example: `"f[0-9]b"`, first matches `"f"`, then a digit and then `"b"`.

```
concat ::= piece
 or piece piece
 or piece piece piece
 etc.
```

`/piece`  
4. A piece is an atom, possibly followed by a multi, an indication of how many times the atom can be matched. Example: `"a*"` matches any sequence of `"a"` characters: `"", "a", "aa",` etc. See `/multi` .

```
piece ::= atom
 or atom multi
```

`/atom`  
5. An atom can be one of a long list of items. Many atoms match one character in the text. It is often an ordinary character or a character class.

Parentheses can be used to make a pattern into an atom. The "\z(\)" construct is only for syntax highlighting.

```
atom ::= ordinary-atom /ordinary-atom
 or \(pattern \) /\(
 or \%(pattern \) /\%(
 or \z(pattern \) /\z(
```

/\%#= two-engines NFA

Vim includes two regexp engines:

1. An old, backtracking engine that supports everything.
2. A new, NFA engine that works much faster on some patterns, possibly slower on some patterns.

E1281

Vim will automatically select the right engine for you. However, if you run into a problem or want to specifically select one engine or the other, you can prepend one of the following to the pattern:

```
\%#=0 Force automatic selection. Only has an effect when
 'regengine' has been set to a non-zero value.
\%#=1 Force using the old engine.
\%#=2 Force using the NFA engine.
```

You can also use the 'regengine' option to change the default.

E864 E868 E874 E875 E876 E877 E878

If selecting the NFA engine and it runs into something that is not implemented the pattern will not match. This is only useful when debugging Vim.

=====  
3. Magic /magic

Some characters in the pattern, such as letters, are taken literally. They match exactly the same character in the text. When preceded with a backslash however, these characters may get a special meaning. For example, "a" matches the letter "a", while "\a" matches any alphabetic character.

Other characters have a special meaning without a backslash. They need to be preceded with a backslash to match literally. For example "." matches any character while "\." matches a dot.

If a character is taken literally or not depends on the 'magic' option and the items in the pattern mentioned next. The 'magic' option should always be set, but it can be switched off for Vi compatibility. We mention the effect of 'nomagic' here for completeness, but we recommend against using that.

```
/\m /\M
```

Use of "\m" makes the pattern after it be interpreted as if 'magic' is set, ignoring the actual value of the 'magic' option.  
Use of "\M" makes the pattern after it be interpreted as if 'nomagic' is used.

```
/\v /\V
```

Use of "\v" means that after it, all ASCII characters except '0'-'9', 'a'-'z', 'A'-'Z' and '\_' have special meaning: "very magic"

Use of "\V" means that after it, only a backslash and the terminating character (usually / or ?) have special meaning: "very nomagic"

Examples:

after:	\v	\m	\M	\V	matches
		'magic'	'nomagic'		
	a	a	a	a	literal 'a'
	\a	\a	\a	\a	any alphabetic character
	.	.	\.	\.	any character
	\.	\.	.	.	literal dot
	\$	\$	\$	\\$	end-of-line
	*	*	\*	\*	any number of the previous atom
	~	~	\~	\~	latest substitute string
	()	\(\)	\(\)	\(\)	group as an atom
		\	\	\	nothing: separates alternatives
	\\	\\	\\	\\	literal backslash
	\{	{	{	{	literal curly brace

{only Vim supports \m, \M, \v and \V}

If you want to you can make a pattern immune to the 'magic' option being set or not by putting "\m" or "\M" at the start of the pattern.

#### 4. Overview of pattern items

[pattern-overview](#)  
[E865](#) [E866](#) [E867](#) [E869](#)

Overview of multi items.

[/multi](#) [E61](#) [E62](#)

More explanation and examples below, follow the links.

[E64](#) [E871](#)

	multi	'magic'	'nomagic'	matches of the preceding atom	
/star	*	\*	\*	0 or more	as many as possible
/\+	\+	\+	\+	1 or more	as many as possible
/\=	\=	\=	\=	0 or 1	as many as possible
/\?	\?	\?	\?	0 or 1	as many as possible
/\{	\{n,m}	\{n,m}	\{n,m}	n to m	as many as possible
	\{n}	\{n}	\{n}	n	exactly
	\{n,}	\{n,}	\{n,}	at least n	as many as possible
	\{,m}	\{,m}	\{,m}	0 to m	as many as possible
	\{}	\{}	\{}	0 or more	as many as possible (same as *)
/\{-	\{-n,m}	\{-n,m}	\{-n,m}	n to m	as few as possible
	\{-n}	\{-n}	\{-n}	n	exactly
	\{-n,}	\{-n,}	\{-n,}	at least n	as few as possible
	\{-,m}	\{-,m}	\{-,m}	0 to m	as few as possible
	\{-}	\{-}	\{-}	0 or more	as few as possible
					<a href="#">E59</a>
/\@>	\@>	\@>	\@>	1, like matching a whole pattern	
/\@=	\@=	\@=	\@=	nothing, requires a match	<a href="#">/zero-width</a>
/\@!	\@!	\@!	\@!	nothing, requires NO match	<a href="#">/zero-width</a>
/\@<=	\@<=	\@<=	\@<=	nothing, requires a match behind	<a href="#">/zero-width</a>

`\@<! \@<! \@<! nothing, requires NO match behind /zero-width`

Overview of ordinary atoms. [/ordinary-atom](#)  
More explanation and examples below, follow the links.

	ordinary atom		
	magic	nomagic	matches
<code>/^</code>	<code>^</code>	<code>^</code>	start-of-line (at start of pattern) <a href="#">/zero-width</a>
<code>/\^</code>	<code>\^</code>	<code>\^</code>	literal '^'
<code>/\_^</code>	<code>\_^</code>	<code>\_^</code>	start-of-line (used anywhere) <a href="#">/zero-width</a>
<code>/\\$\$</code>	<code>\\$\$</code>	<code>\\$\$</code>	end-of-line (at end of pattern) <a href="#">/zero-width</a>
<code>/\_\$</code>	<code>\_\$</code>	<code>\_\$</code>	literal '\$'
<code>/\_\$\$</code>	<code>\\_\$\$</code>	<code>\\_\$\$</code>	end-of-line (used anywhere) <a href="#">/zero-width</a>
<code>/.</code>	<code>.</code>	<code>.</code>	any single character (not an end-of-line)
<code>/\_.</code>	<code>\_.</code>	<code>\_.</code>	any single character or end-of-line
<code>/\&lt;</code>	<code>\&lt;</code>	<code>\&lt;</code>	beginning of a word <a href="#">/zero-width</a>
<code>/\&gt;</code>	<code>\&gt;</code>	<code>\&gt;</code>	end of a word <a href="#">/zero-width</a>
<code>/\zs</code>	<code>\zs</code>	<code>\zs</code>	anything, sets start of match
<code>/\ze</code>	<code>\ze</code>	<code>\ze</code>	anything, sets end of match
<code>/\%^</code>	<code>\%^</code>	<code>\%^</code>	beginning of file <a href="#">/zero-width</a> <span style="float:right">E71</span>
<code>/\%\$</code>	<code>\%\$</code>	<code>\%\$</code>	end of file <a href="#">/zero-width</a>
<code>/\%V</code>	<code>\%V</code>	<code>\%V</code>	inside Visual area <a href="#">/zero-width</a>
<code>/\%#</code>	<code>\%#</code>	<code>\%#</code>	cursor position <a href="#">/zero-width</a>
<code>/\%'m</code>	<code>\%'m</code>	<code>\%'m</code>	mark m position <a href="#">/zero-width</a>
<code>/\%l</code>	<code>\%23l</code>	<code>\%23l</code>	in line 23 <a href="#">/zero-width</a>
<code>/\%c</code>	<code>\%23c</code>	<code>\%23c</code>	in column 23 <a href="#">/zero-width</a>
<code>/\%v</code>	<code>\%23v</code>	<code>\%23v</code>	in virtual column 23 <a href="#">/zero-width</a>

Character classes: [/character-classes](#)

	magic	nomagic	matches
<code>/\i</code>	<code>\i</code>	<code>\i</code>	identifier character (see ' <b>isident</b> ' option)
<code>/\I</code>	<code>\I</code>	<code>\I</code>	like "\i", but excluding digits
<code>/\k</code>	<code>\k</code>	<code>\k</code>	keyword character (see ' <b>iskeyword</b> ' option)
<code>/\K</code>	<code>\K</code>	<code>\K</code>	like "\k", but excluding digits
<code>/\f</code>	<code>\f</code>	<code>\f</code>	file name character (see ' <b>isfname</b> ' option)
<code>/\F</code>	<code>\F</code>	<code>\F</code>	like "\f", but excluding digits
<code>/\p</code>	<code>\p</code>	<code>\p</code>	printable character (see ' <b>isprint</b> ' option)
<code>/\P</code>	<code>\P</code>	<code>\P</code>	like "\p", but excluding digits
<code>/\s</code>	<code>\s</code>	<code>\s</code>	whitespace character: <Space> and <Tab>
<code>/\S</code>	<code>\S</code>	<code>\S</code>	non-whitespace character; opposite of \s
<code>/\d</code>	<code>\d</code>	<code>\d</code>	digit: <a href="#">[0-9]</a>
<code>/\D</code>	<code>\D</code>	<code>\D</code>	non-digit: <a href="#">[^0-9]</a>
<code>/\x</code>	<code>\x</code>	<code>\x</code>	hex digit: <a href="#">[0-9A-Fa-f]</a>
<code>/\X</code>	<code>\X</code>	<code>\X</code>	non-hex digit: <a href="#">[^0-9A-Fa-f]</a>
<code>/\o</code>	<code>\o</code>	<code>\o</code>	octal digit: <a href="#">[0-7]</a>
<code>/\O</code>	<code>\O</code>	<code>\O</code>	non-octal digit: <a href="#">[^0-7]</a>
<code>/\w</code>	<code>\w</code>	<code>\w</code>	word character: <a href="#">[0-9A-Za-z_]</a>
<code>/\W</code>	<code>\W</code>	<code>\W</code>	non-word character: <a href="#">[^0-9A-Za-z_]</a>
<code>/\h</code>	<code>\h</code>	<code>\h</code>	head of word character: <a href="#">[A-Za-z_]</a>
<code>/\H</code>	<code>\H</code>	<code>\H</code>	non-head of word character: <a href="#">[^A-Za-z_]</a>
<code>/\a</code>	<code>\a</code>	<code>\a</code>	alphabetic character: <a href="#">[A-Za-z]</a>
<code>/\A</code>	<code>\A</code>	<code>\A</code>	non-alphabetic character: <a href="#">[^A-Za-z]</a>
<code>/\l</code>	<code>\l</code>	<code>\l</code>	lowercase character: <a href="#">[a-z]</a>

<code>/\L</code>	<code>\L</code>	<code>\L</code>	non-lowercase character:	<code>[^a-z]</code>
<code>/\u</code>	<code>\u</code>	<code>\u</code>	uppercase character:	<code>[A-Z]</code>
<code>/\U</code>	<code>\U</code>	<code>\U</code>	non-uppercase character	<code>[^A-Z]</code>
<code>/\_</code>	<code>\_x</code>	<code>\_x</code>	where x is any of the characters above:	character class with end-of-line included

(end of character classes)

	magic	nomagic	matches
<code>/\e</code>	<code>\e</code>	<code>\e</code>	<Esc>
<code>/\t</code>	<code>\t</code>	<code>\t</code>	<Tab>
<code>/\r</code>	<code>\r</code>	<code>\r</code>	<CR>
<code>/\b</code>	<code>\b</code>	<code>\b</code>	<BS>
<code>/\n</code>	<code>\n</code>	<code>\n</code>	end-of-line
<code>/~</code>	<code>~</code>	<code>~</code>	last given substitute string
<code>/\1</code>	<code>\1</code>	<code>\1</code>	same string as matched by first <code>\()</code>
<code>/\2</code>	<code>\2</code>	<code>\2</code>	Like <code>"\1"</code> , but uses second <code>\()</code>
<code>/\9</code>	<code>\9</code>	<code>\9</code>	Like <code>"\1"</code> , but uses ninth <code>\()</code>
<code>/\z1</code>	<code>\z1</code>	<code>\z1</code>	only for syntax highlighting, see <a href="#">:syn-ext-match</a> <span style="float: right;">E68</span>
<code>/\z1</code>	<code>\z9</code>	<code>\z9</code>	only for syntax highlighting, see <a href="#">:syn-ext-match</a>
	<code>x</code>	<code>x</code>	a character with no special meaning matches itself
<code>/[[]</code>	<code>[]</code>	<code>\[[]</code>	any character specified inside the <code>[]</code>
<code>/\%[]</code>	<code>\%[]</code>	<code>\%[]</code>	a sequence of optionally matched atoms
<code>/\c</code>	<code>\c</code>	<code>\c</code>	ignore case, do not use the <b>'ignorecase'</b> option
<code>/\C</code>	<code>\C</code>	<code>\C</code>	match case, do not use the <b>'ignorecase'</b> option
<code>/\Z</code>	<code>\Z</code>	<code>\Z</code>	ignore differences in Unicode "combining characters". Useful when searching voweled Hebrew or Arabic text.

	magic	nomagic	matches
<code>/\m</code>	<code>\m</code>	<code>\m</code>	<b>'magic'</b> on for the following chars in the pattern
<code>/\M</code>	<code>\M</code>	<code>\M</code>	<b>'magic'</b> off for the following chars in the pattern
<code>/\v</code>	<code>\v</code>	<code>\v</code>	the following chars in the pattern are "very magic"
<code>/\V</code>	<code>\V</code>	<code>\V</code>	the following chars in the pattern are "very nomagic"
<code>/\%#=</code>	<code>\%#=1</code>	<code>\%#=1</code>	select regexp engine <a href="#">/zero-width</a>
<code>/\%d</code>	<code>\%d</code>	<code>\%d</code>	match specified decimal character (eg <code>\%d123</code> )
<code>/\%x</code>	<code>\%x</code>	<code>\%x</code>	match specified hex character (eg <code>\%x2a</code> )
<code>/\%o</code>	<code>\%o</code>	<code>\%o</code>	match specified octal character (eg <code>\%o040</code> )
<code>/\%u</code>	<code>\%u</code>	<code>\%u</code>	match specified multibyte character (eg <code>\%u20ac</code> )
<code>/\%U</code>	<code>\%U</code>	<code>\%U</code>	match specified large multibyte character (eg <code>\%U12345678</code> )
<code>/\%C</code>	<code>\%C</code>	<code>\%C</code>	match any composing characters

#### Example

```

\<\I\i* or
\<\h\w*
\<[a-zA-Z_][a-zA-Z0-9_]*

```

#### matches

An identifier (e.g., in a C program).

`\(\. $\ | \. \)` A period followed by `<EOL>` or a space.

`[.!?][ ]*"')*\($\|[ ]\)` A search pattern that finds the end of a sentence, with almost the same definition as the `"")` command.

`cat\Z` Both "cat" and "càt" ("a" followed by `0x0300`)  
Does not match "càt" (character `0x00e0`), even though it may look the same.

## 5. Multi items

[pattern-multi-items](#)

An atom can be followed by an indication of how many times the atom can be matched and in what way. This is called a multi. See [/multi](#) for an overview.

`*` (use `\*` when `'magic'` is not set) [/star](#) [/\star](#)  
Matches 0 or more of the preceding atom, as many as possible.  
**Example** `'nomagic'` **matches**  
`a*` `a\*` `"", "a", "aa", "aaa", etc.`  
`.*` `\. \*` `anything, also an empty string, no end-of-line`  
`\_.*` `\_.*\*` `everything up to the end of the buffer`  
`\_.*END` `\_.*\*END` `everything up to and including the last "END" in the buffer`

Exception: When `"*"` is used at the start of the pattern or just after `"^"` it matches the star character.

Be aware that repeating `"\_."` can match a lot of text and take a long time. For example, `"\_.*END"` matches all text from the current position to the last occurrence of "END" in the file. Since the `"*"` will match as many as possible, this first skips over all lines until the end of the file and then tries matching "END", backing up one character at a time.

`\+` [/\+](#)  
Matches 1 or more of the preceding atom, as many as possible.  
**Example** **matches**  
`^\.+ $` `any non-empty line`  
`\s\+` `white space of at least one character`

`\=` [/\=](#)  
Matches 0 or 1 of the preceding atom, as many as possible.  
**Example** **matches**  
`foo\=` `"fo" and "foo"`

`\?` [/\?](#)  
Just like `\=`. Cannot be used when searching backwards with the `"?"` command.

`\{n,m}` [/\{](#) [E60](#) [E554](#) [E870](#)  
Matches n to m of the preceding atom, as many as possible

`\{n}` Matches n of the preceding atom  
`\{n,}` Matches at least n of the preceding atom, as many as possible  
`\{,m}` Matches 0 to m of the preceding atom, as many as possible  
`\{ }` Matches 0 or more of the preceding atom, as many as possible (like \*)

/`\{-`

`\{-n,m}` matches n to m of the preceding atom, as few as possible  
`\{-n}` matches n of the preceding atom  
`\{-n,}` matches at least n of the preceding atom, as few as possible  
`\{-,m}` matches 0 to m of the preceding atom, as few as possible  
`\{-}` matches 0 or more of the preceding atom, as few as possible

n and m are positive decimal numbers or zero

non-greedy

If a "-" appears immediately after the "{", then a shortest match first algorithm is used (see example below). In particular, "{-}" is the same as "\*" but uses the shortest match first algorithm. BUT: A match that starts earlier is preferred over a shorter match: "a{-}b" matches "aaab" in "xaaab".

Example	matches
<code>ab\{2,3}c</code>	"abbc" or "abbbc"
<code>a\{5}</code>	"aaaaa"
<code>ab\{2,}c</code>	"abbc", "abbbc", "abbbbc", etc.
<code>ab\{,3}c</code>	"ac", "abc", "abbc" or "abbbc"
<code>a[bc]\{3}d</code>	"abbbd", "abbbcd", "acbcd", "accdd", etc.
<code>a(bc)\{1,2}d</code>	"abcd" or "abcbcd"
<code>a[bc]\{-}[cd]</code>	"abc" in "abcd"
<code>a[bc]*[cd]</code>	"abcd" in "abcd"

The } may optionally be preceded with a backslash: `\{n,m\}`.

/`\@=`

`\@=` Matches the preceding atom with zero width. Like "(?=pattern)" in Perl.

Example	matches
<code>foo(bar)\@=</code>	"foo" in "foobar"
<code>foo(bar)\@=foo</code>	nothing

/zero-width

When using "@=" (or "^", "\$", "<", ">") no characters are included in the match. These items are only used to check if a match can be made. This can be tricky, because a match with following items will be done in the same position. The last example above will not match "foobarfoo", because it tries match "foo" in the same position where "bar" matched.

**Note** that using "&" works the same as using "@=": "foo&.." is the same as "(foo)\@=..". But using "&" is easier, you don't need the parentheses.

/`\@!`

`\@!` Matches with zero width if the preceding atom does NOT match at the current position. /zero-width  
Like "(?!pattern)" in Perl.

<b>Example</b>	<b>matches</b>
foo\(\bar\) \@!	any "foo" not followed by "bar"
a.\{-}p \@!	"a", "ap", "app", "app", etc. not immediately followed by a "p"
if \(\(then\) \@!\.)*\$	"if " not followed by "then"

Using "\@" is tricky, because there are many places where a pattern does not match. "a.\*p\@" will match from an "a" to the end of the line, because "." can match all characters in the line and the "p" doesn't match at the end of the line. "a.\{-}p\@" will match any "a", "ap", "app", etc. that isn't followed by a "p", because the "." can match a "p" and "p\@" doesn't match after that.

You can't use "\@" to look for a non-match before the matching position: "\(\foo\) \@!bar" will match "bar" in "foobar", because at the position where "bar" matches, "foo" does not match. To avoid matching "foobar" you could use "\(\foo\) \@!...bar", but that doesn't match a bar at the start of a line. Use "\(\foo\) \@<!bar".

Useful example: to find "foo" in a line that does not contain "bar":  
`/^\%(.*bar\) \@!.*\zsfoo`

This pattern first checks that there is not a single position in the line where "bar" matches. If ".\*bar" matches somewhere the \@! will reject the pattern. When there is no match any "foo" will be found. The "\zs" is to have the match start just before "foo".

<code>\@&lt;=</code>	<code>/\@&lt;=</code>	Matches with zero width if the preceding atom matches just before what follows. <code>/zero-width</code> Like "(?<=pattern)" in Perl, but Vim allows non-fixed-width patterns.
----------------------	-----------------------	-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

<b>Example</b>	<b>matches</b>
\(an\_s\+)\ \@<=file	"file" after "an" and white space or an end-of-line

For speed it's often much better to avoid this multi. Try using "\zs" instead `/\zs`. To match the same as the above example:  
`an\_s\+\zsfile`

At least set a limit for the look-behind, see below.

"\@<=" and "\@<!" check for matches just before what follows. Theoretically these matches could start anywhere before this position. But to limit the time needed, only the line where what follows matches is searched, and one line before that (if there is one). This should be sufficient to match most things and not be too slow.

In the old regexp engine the part of the pattern after "\@<=" and "\@<!" are checked for a match first, thus things like "\1" don't work to reference \(\) inside the preceding atom. It does work the other way around:

<b>Bad example</b>	<b>matches</b>
\%#=1\1\ \@<=,\([a-z]\+\)	",abc" in "abc,abc"

However, the new regexp engine works differently, it is better to not rely on this behavior, do not use \@<= if it can be avoided:

<b>Example</b>	<b>matches</b>
----------------	----------------

`\([a-z]\+\\)\zs,\1`                   ",abc" in "abc,abc"

`\@123<=`

Like "`\@<=`" but only look back 123 bytes. This avoids trying lots of matches that are known to fail and make executing the pattern very slow. Example, check if there is a "<" just before "span":

`/<\@1<=span`

This will try matching "<" only one byte before "span", which is the only place that works anyway.

After crossing a line boundary, the limit is relative to the end of the line. Thus the characters at the start of the line with the match are not counted (this is just to keep it simple).

The number zero is the same as no limit.

`\@<!`

Matches with zero width if the preceding atom does NOT match just before what follows. Thus this matches if there is no position in the current or previous line where the atom matches such that it ends just before what follows. /zero-width

Like "`(?<!pattern)`" in Perl, but Vim allows non-fixed-width patterns. The match with the preceding atom is made to end just before the match with what follows, thus an atom that ends in `.*` will work.

Warning: This can be slow (because many positions need to be checked for a match). Use a limit if you can, see below.

**Example**

**matches**

`\(foo\)\@<!bar`

any "bar" that's not in "foobar"

`\(\\\/.*\)\@<!in`

"in" which is not after "//"

`\@123<!`

Like "`\@<!`" but only look back 123 bytes. This avoids trying lots of matches that are known to fail and make executing the pattern very slow.

`\@>`

Matches the preceding atom like matching a whole pattern. Like "`(?>pattern)`" in Perl.

**Example**

**matches**

`\(a*\)\@>a`

nothing (the "a\*" takes all the "a"'s, there can't be another one following)

This matches the preceding atom as if it was a pattern by itself. If it doesn't match, there is no retry with shorter sub-matches or anything. Observe this difference: "a\*b" and "a\*ab" both match "aaab", but in the second case the "a\*" matches only the first two "a"s. "`\(a*\)\@>ab`" will not match "aaab", because the "a\*" matches the "aaa" (as many "a"s as possible), thus the "ab" can't match.

---

## 6. Ordinary atoms

pattern-atoms

An ordinary atom can be:

/^

`^` At beginning of pattern or after "`\\`", "`\(`", "`\%(`" or "`\n`": matches start-of-line; at other positions, matches literal '`^`'. `/zero-width`  
**Example** `^beep(` matches the start of the C function "beep" (probably).

`\^` Matches literal '`^`'. Can be used at any position in the pattern, but not inside `[]`. `/\^`

`\_``^` Matches start-of-line. `/zero-width` Can be used at any position in the pattern, but not inside `[]`. `/\_``^`  
**Example** `\_s*\_``^``foo` matches white space and blank lines and then "foo" at start-of-line

`$` At end of pattern or in front of "`\\`", "`\)`" or "`\n`" ('magic' on): matches end-of-line `<EOL>`; at other positions, matches literal '`$`'. `/zero-width` `/``$`

`\$` Matches literal '`$`'. Can be used at any position in the pattern, but not inside `[]`. `/\``$`

`\_``$` Matches end-of-line. `/zero-width` Can be used at any position in the pattern, but not inside `[]`. **Note** that "`a\_``$``b`" never matches, since "`b`" cannot match an end-of-line. Use "`a\n`" instead `/\``n` `.`  
**Example** `foo\_``$``\_``s*` matches "foo" at end-of-line and following white space and blank lines

`.` (with '**nomagic**': `\.`) `/.` `/\.`  
Matches any single character, but not an end-of-line.

`\_.` Matches any single character or end-of-line. `/\_.`  
Careful: "`\_.*`" matches all text to the end of the buffer!

`\<` Matches the beginning of a word: The next char is the first char of a word. The '**iskeyword**' option specifies what is a word character. `/zero-width` `/\<`

`\>` Matches the end of a word: The previous char is the last char of a word. The '**iskeyword**' option specifies what is a word character. `/zero-width` `/\>`

`\zs` Matches at any position, but not inside `[]`, and sets the start of the match there: The next char is the first char of the whole match. `/\zs` `/zero-width`

Example:

```
/^\s*\zsif
```

matches an "if" at the start of a line, ignoring white space.

Can be used multiple times, the last one encountered in a matching branch is used. Example:

```
/\(.{\-}\zsFab\)\{3}
```

Finds the third occurrence of "Fab".

This cannot be followed by a multi. E888

{not available when compiled without the |+syntax| feature}

```
/\ze
```

`\ze` Matches at any position, but not inside [], and sets the end of the match there: The previous char is the last char of the whole match.

```
/zero-width
```

Can be used multiple times, the last one encountered in a matching branch is used.

Example: "end\ze(if\|for\)" matches the "end" in "endif" and "endfor".

This cannot be followed by a multi. E888

{not available when compiled without the |+syntax| feature}

```
/\%^ start-of-file
```

`\%^` Matches start of the file. When matching with a string, matches the start of the string.

For example, to find the first "VIM" in a file:

```
/\%^_{-}\zsVIM
```

```
/\%$ end-of-file
```

`\%$` Matches end of the file. When matching with a string, matches the end of the string.

Note that this does NOT find the last "VIM" in a file:

```
/VIM_{-}\%$
```

It will find the next VIM, because the part after it will always match. This one will find the last "VIM" in the file:

```
/VIM\ze(\(VIM\) \@!_{-}\)*\%$
```

This uses `/\@!` to ascertain that "VIM" does NOT match in any position after the first "VIM".

Searching from the end of the file backwards is easier!

```
/\%V
```

`\%V` Match inside the Visual area. When Visual mode has already been stopped match in the area that `gv` would reselect.

This is a `/zero-width` match. To make sure the whole pattern is inside the Visual area put it at the start and just before the end of the pattern, e.g.:

```
/\%Vfoo.*ba\%Vr
```

This also works if only "foo bar" was Visually selected. This:

```
/\%Vfoo.*bar\%V
```

would match "foo bar" if the Visual selection continues after the "r".

Only works for the current buffer.

```
/\%# cursor-position
```

`\%#` Matches with the cursor position. Only works when matching in a buffer displayed in a window.

WARNING: When the cursor is moved after the pattern was used, the

result becomes invalid. Vim doesn't automatically update the matches. This is especially relevant for syntax highlighting and **'hlsearch'**. In other words: When the cursor moves the display isn't updated for this change. An update is done for lines which are changed (the whole line is updated) or when using the **CTRL-L** command (the whole screen is updated). Example, to highlight the word under the cursor:

```
/\k*\%#\k*
```

When **'hlsearch'** is set and you move the cursor around and make changes this will clearly show when the match is updated or not.

```
/\%'m /\%<'m /\%>'m
```

```
\%'m Matches with the position of mark m.
\%<'m Matches before the position of mark m.
\%>'m Matches after the position of mark m.
Example, to highlight the text from mark 's to 'e:
/.\%>'s.*\%<'e..
```

**Note** that two dots are required to include mark 'e in the match. That is because `"\%<'e"` matches at the character before the 'e mark, and since it's a **/zero-width** match it doesn't include that character. **WARNING:** When the mark is moved after the pattern was used, the result becomes invalid. Vim doesn't automatically update the matches. Similar to moving the cursor for `"\%#" /%\%#`.

```
/\%l /\%>l /\%<l E951 E1204 E1273
```

```
\%23l Matches in a specific line.
\%<23l Matches above a specific line (lower line number).
\%>23l Matches below a specific line (higher line number).
\%.l Matches at the cursor line.
\%<.l Matches above the cursor line.
\%>.l Matches below the cursor line.
```

These six can be used to match specific lines in a buffer. The "23" can be any line number. The first line is 1. **WARNING:** When inserting or deleting lines Vim does not automatically update the matches. This means Syntax highlighting quickly becomes wrong. Also when referring to the cursor position (".") and the cursor moves the display isn't updated for this change. An update is done when using the **CTRL-L** command (the whole screen is updated). Example, to highlight the line where the cursor currently is:

```
:exe '/\%' . line(".") . 'l'
```

Alternatively use:

```
/\%.l
```

When **'hlsearch'** is set and you move the cursor around and make changes this will clearly show when the match is updated or not.

```
/\%c /\%>c /\%<c
```

```
\%23c Matches in a specific column.
\%<23c Matches before a specific column.
\%>23c Matches after a specific column.
\%.c Matches at the cursor column.
\%<.c Matches before the cursor column.
\%>.c Matches after the cursor column.
```

These six can be used to match specific columns in a buffer or string. The "23" can be any column number. The first column is 1. Actually, the column is the byte number (thus it's not exactly right for

multibyte characters).

WARNING: When inserting or deleting text Vim does not automatically update the matches. This means Syntax highlighting quickly becomes wrong. Also when referring to the cursor position (".") and the cursor moves the display isn't updated for this change. An update is done when using the **CTRL-L** command (the whole screen is updated). Example, to highlight the column where the cursor currently is:

```
:exe '/\%' .. col(".") .. 'c'
```

Alternatively use:

```
/\%.c
```

When **'hlsearch'** is set and you move the cursor around and make changes this will clearly show when the match is updated or not.

Example for matching a single byte in column 44:

```
/\%>43c.\%<46c
```

**Note** that "\%<46c" matches in column 45 when the "." matches a byte in column 44.

```
/\%v /\%>v /\%<v
```

`\%23v` Matches in a specific virtual column.  
`\%<23v` Matches before a specific virtual column.  
`\%>23v` Matches after a specific virtual column.  
`\%.v` Matches at the current virtual column.  
`\%<.v` Matches before the current virtual column.  
`\%>.v` Matches after the current virtual column.

These six can be used to match specific virtual columns in a buffer or string. When not matching with a buffer in a window, the option values of the current window are used (e.g., **'tabstop'**).

The "23" can be any column number. The first column is 1.

**Note** that some virtual column positions will never match, because they are halfway through a tab or other character that occupies more than one screen character.

WARNING: When inserting or deleting text Vim does not automatically update highlighted matches. This means Syntax highlighting quickly becomes wrong. Also when referring to the cursor position (".") and the cursor moves the display isn't updated for this change. An update is done when using the **CTRL-L** command (the whole screen is updated). Example, to highlight all the characters after virtual column 72:

```
/\%>72v.*
```

When **'hlsearch'** is set and you move the cursor around and make changes this will clearly show when the match is updated or not.

To match the text up to column 17:

```
/^.*\%17v
```

To match all characters after the current virtual column (where the cursor is):

```
/\%>.v.*
```

Column 17 is not included, because this is a **/zero-width** match. To include the column use:

```
/^.*\%17v.
```

This command does the same thing, but also matches when there is no character in column 17:

```
/^.*\%<18v.
```

**Note** that without the "^" to anchor the match in the first column, this will also highlight column 17:

```
/.*\%17v
```

Column 17 is highlighted by **'hlsearch'** because there is another match

where "." matches zero characters.

Character classes:

<code>\i</code>	identifier character (see <b>'isident'</b> option)	<code>/\i</code>
<code>\I</code>	like " <code>\i</code> ", but excluding digits	<code>/\I</code>
<code>\k</code>	keyword character (see <b>'iskeyword'</b> option)	<code>/\k</code>
<code>\K</code>	like " <code>\k</code> ", but excluding digits	<code>/\K</code>
<code>\f</code>	file name character (see <b>'isfname'</b> option)	<code>/\f</code>
<code>\F</code>	like " <code>\f</code> ", but excluding digits	<code>/\F</code>
<code>\p</code>	printable character (see <b>'isprint'</b> option)	<code>/\p</code>
<code>\P</code>	like " <code>\p</code> ", but excluding digits	<code>/\P</code>

**NOTE:** the above also work for multibyte characters. The ones below only match ASCII characters, as indicated by the range.

		whitespace	white-space
<code>\s</code>	whitespace character: <code>&lt;Space&gt;</code> and <code>&lt;Tab&gt;</code>	<code>/\s</code>	
<code>\S</code>	non-whitespace character; opposite of <code>\s</code>	<code>/\S</code>	
<code>\d</code>	digit: <code>[0-9]</code>	<code>/\d</code>	
<code>\D</code>	non-digit: <code>[^0-9]</code>	<code>/\D</code>	
<code>\x</code>	hex digit: <code>[0-9A-Fa-f]</code>	<code>/\x</code>	
<code>\X</code>	non-hex digit: <code>[^0-9A-Fa-f]</code>	<code>/\X</code>	
<code>\o</code>	octal digit: <code>[0-7]</code>	<code>/\o</code>	
<code>\O</code>	non-octal digit: <code>[^0-7]</code>	<code>/\O</code>	
<code>\w</code>	word character: <code>[0-9A-Za-z_]</code>	<code>/\w</code>	
<code>\W</code>	non-word character: <code>[^0-9A-Za-z_]</code>	<code>/\W</code>	
<code>\h</code>	head of word character: <code>[A-Za-z_]</code>	<code>/\h</code>	
<code>\H</code>	non-head of word character: <code>[^A-Za-z_]</code>	<code>/\H</code>	
<code>\a</code>	alphabetic character: <code>[A-Za-z]</code>	<code>/\a</code>	
<code>\A</code>	non-alphabetic character: <code>[^A-Za-z]</code>	<code>/\A</code>	
<code>\l</code>	lowercase character: <code>[a-z]</code>	<code>/\l</code>	
<code>\L</code>	non-lowercase character: <code>[^a-z]</code>	<code>/\L</code>	
<code>\u</code>	uppercase character: <code>[A-Z]</code>	<code>/\u</code>	
<code>\U</code>	non-uppercase character: <code>[^A-Z]</code>	<code>/\U</code>	

**NOTE:** Using the atom is faster than the `[]` form.

**NOTE:** **'ignorecase'**, `"\c"` and `"\C"` are not used by character classes.

<code>/\_</code>	<code>E63</code>	<code>/\_i</code>	<code>/\_I</code>	<code>/\_k</code>	<code>/\_K</code>	<code>/\_f</code>	<code>/\_F</code>
<code>/\_p</code>	<code>/\_P</code>	<code>/\_s</code>	<code>/\_S</code>	<code>/\_d</code>	<code>/\_D</code>	<code>/\_x</code>	<code>/\_X</code>
<code>/\_o</code>	<code>/\_O</code>	<code>/\_w</code>	<code>/\_W</code>	<code>/\_h</code>	<code>/\_H</code>	<code>/\_a</code>	<code>/\_A</code>
<code>/\_l</code>	<code>/\_L</code>	<code>/\_u</code>	<code>/\_U</code>				

`\_x` Where "x" is any of the characters above: The character class with end-of-line added

(end of character classes)

<code>\e</code>	matches <code>&lt;Esc&gt;</code>	<code>/\e</code>
<code>\t</code>	matches <code>&lt;Tab&gt;</code>	<code>/\t</code>
<code>\r</code>	matches <code>&lt;CR&gt;</code>	<code>/\r</code>
<code>\b</code>	matches <code>&lt;BS&gt;</code>	<code>/\b</code>
<code>\n</code>	matches an end-of-line	<code>/\n</code>

When matching in a string instead of buffer text a literal newline

character is matched.

- ~ matches the last given substitute string      /~    /\~
  
- \(\) A pattern enclosed by escaped parentheses.      /\(    /\(\)    /\)  
E.g., "\(^a\)" matches 'a' at the start of a line.  
There can only be nine of these. You can use "%(" to add more, but not counting it as a sub-expression.  
E51    E54    E55    E872    E873
  
- \1 Matches the same string that was matched by      /\1    E65  
the first sub-expression in \( and \).  
Example: "\([a-z]\).\1" matches "ata", "ehe", "tot", etc.
- \2 Like "\1", but uses second sub-expression,      /\2
- ...      /\3
- \9 Like "\1", but uses ninth sub-expression.      /\9  
**Note:** The numbering of groups is done based on which "(" comes first in the pattern (going left to right), NOT based on what is matched first.
  
- \%(%) A pattern enclosed by escaped parentheses.      /\%(%)    /\%(    E53  
Just like \(\), but without counting it as a sub-expression. This allows using more groups and it's a little bit faster.
  
- x A single character, with no special meaning, matches itself
  
- \x A backslash followed by a single character, with no special meaning, is reserved for future expansions      /\    /\\
  
- [] (with 'nomagic': \[])      /[]    /\[]    /\\_[]    /collection    E76  
\\_[]  
A collection. This is a sequence of characters enclosed in square brackets. It matches any single character in the collection.  
Example      matches  
[xyz]      any 'x', 'y' or 'z'  
[a-zA-Z]\$      any alphabetic character at the end of a line  
\c[a-z]\$      same  
[␣-␣␣␣]      Russian alphabet (with utf-8 and cp1251)
  
- With "\\_" prepended the collection also includes the end-of-line.      /[\n]  
The same can be done by including "\n" in the collection. The end-of-line is also matched when the collection starts with "^"! Thus "\\_[^ab]" matches the end-of-line and any character but "a" and "b". This makes it Vi compatible: Without the "\\_" or "\n" the collection does not match an end-of-line.  
E769
  
- When the ']' is not there Vim will not give an error message but assume no collection is used. Useful to search for '['. However, you do get E769 for internal searching. And be aware that in a `:substitute` command the whole command becomes the pattern. E.g. ":s/[x]/" searches for "[x]" and replaces it with nothing. It does not search for "[" and replaces it with "x"!

If the sequence begins with "^", it matches any single character NOT in the collection: "[^xyz]" matches anything but 'x', 'y' and 'z'.

- If two characters in the sequence are separated by '-', this is shorthand for the full list of ASCII characters between them. E.g., "[0-9]" matches any decimal digit. If the starting character exceeds the ending character, e.g. [c-a], E944 occurs. Non-ASCII characters can be used, but the character values must not be more than 256 apart in the old regexp engine. For example, searching by [\u3000-\u4000] after setting re=1 emits a E945 error. Prepending \##=2 will fix it.
- A character class expression is evaluated to the set of characters belonging to that character class. The following character classes are supported:

	Name	Func	Contents
<code>[:alnum:]</code>	<code>[:alnum:]</code>	isalnum	ASCII letters and digits
<code>[:alpha:]</code>	<code>[:alpha:]</code>	isalpha	ASCII letters
<code>[:blank:]</code>	<code>[:blank:]</code>		space and tab
<code>[:cntrl:]</code>	<code>[:cntrl:]</code>	iscntrl	ASCII control characters
<code>[:digit:]</code>	<code>[:digit:]</code>		decimal digits '0' to '9'
<code>[:graph:]</code>	<code>[:graph:]</code>	isgraph	ASCII printable characters excluding space
<code>[:lower:]</code>	<code>[:lower:]</code>	(1)	lowercase letters (all letters when <b>'ignorecase'</b> is used)
<code>[:print:]</code>	<code>[:print:]</code>	(2)	printable characters including space
<code>[:punct:]</code>	<code>[:punct:]</code>	ispunct	ASCII punctuation characters
<code>[:space:]</code>	<code>[:space:]</code>		whitespace characters: space, tab, CR, NL, vertical tab, form feed
<code>[:upper:]</code>	<code>[:upper:]</code>	(3)	uppercase letters (all letters when <b>'ignorecase'</b> is used)
<code>[:xdigit:]</code>	<code>[:xdigit:]</code>		hexadecimal digits: 0-9, a-f, A-F
<code>[:return:]</code>	<code>[:return:]</code>		the <CR> character
<code>[:tab:]</code>	<code>[:tab:]</code>		the <Tab> character
<code>[:escape:]</code>	<code>[:escape:]</code>		the <Esc> character
<code>[:backspace:]</code>	<code>[:backspace:]</code>		the <BS> character
<code>[:ident:]</code>	<code>[:ident:]</code>		identifier character (same as "\i")
<code>[:keyword:]</code>	<code>[:keyword:]</code>		keyword character (same as "\k")
<code>[:fname:]</code>	<code>[:fname:]</code>		file name character (same as "\f")

The square brackets in character class expressions are additional to the square brackets delimiting a collection. For example, the following is a plausible pattern for a UNIX filename:

"[-./[:alnum:]\_~]\+". That is, a list of at least one character, each of which is either '-', '.', '/', alphabetic, numeric, '\_' or '~'.

These items only work for 8-bit characters, except `[:lower:]` and `[:upper:]` also work for multibyte characters when using the new regexp engine. See [two-engines](#). In the future these items may work for multibyte characters. For now, to get all "alpha" characters you can use: `[:lower:][:upper:]`.

The "Func" column shows what library function is used. The implementation depends on the system. Otherwise:

(1) Uses `islower()` for ASCII and Vim builtin rules for other characters.

- (2) Uses Vim builtin rules
- (3) As with (1) but using isupper()

/[ [= ] == ]

- An equivalence class. This means that characters are matched that have almost the same meaning, e.g., when ignoring accents. This only works for Unicode, latin1 and latin9. The form is:

[=a=]

/[ [. ] .. ]

- A collation element. This currently simply accepts a single character in the form:

[.a.]

/[ \ ]

- To include a literal ']', '^', '-' or '\' in the collection, put a backslash before it: "[xyz\]", "[\^xyz]", "[xy\-z]" and "[xyz\\]". (Note: POSIX does not support the use of a backslash this way). For '[' you can also make it the first character (following a possible "^"): "[ ]xyz]" or "[^]xyz]".

For '-' you can also make it the first or last character: "[-xyz]", "[^ -xyz]" or "[xyz-]". For '\' you can also let it be followed by any character that's not in "^] -\bdertnoUux". "[\xyz]" matches '\', 'x', 'y' and 'z'. It's better to use "\\\" though, future expansions may use other characters after '\\'.

- Omitting the trailing ] is not considered an error. "[]" works like "[ ]]", it matches the ']' character.
- The following translations are accepted when the 'l' flag is not included in '**coptions**':

```

\e <Esc>
\t <Tab>
\r <CR> (NOT end-of-line!)
\b <BS>
\n line break, see above /[\n]
\d123 decimal number of character
\o40 octal number of character up to 0o377
\x20 hexadecimal number of character up to 0xff
\u20AC hex. number of multibyte character up to 0xffff
\U1234 hex. number of multibyte character up to 0xffffffff

```

**NOTE:** The other backslash codes mentioned above do not work inside [ ]!

- Matching with a collection can be slow, because each character in the text has to be compared with each character in the collection. Use one of the other atoms above when possible. Example: "\d" is much faster than "[0-9]" and matches the same characters. However, the new **NFA** regexp engine deals with this better than the old one.

/[ % [ ] E69 E70 E369

\% [ ] A sequence of optionally matched atoms. This always matches. It matches as much of the list of atoms it contains as possible. Thus it stops at the first atom that doesn't match. For example:

/r \% [ead]

matches "r", "re", "rea" or "read". The longest that matches is used.

To match the Ex command "function", where "fu" is required and "nction" is optional, this would work:

/[ <fu \% [nction] \>

The end-of-word atom "\>" is used to avoid matching "fu" in "full".

It gets more complicated when the atoms are not ordinary characters. You don't often have to use it, but it is possible. Example:

```
</> \<r\%[[eo]ad]\>
```

Matches the words "r", "re", "ro", "rea", "roa", "read" and "road".

There can be no `\(\)`, `\%(\\)` or `\z(\)` items inside the `[]` and `\%[]` does not nest.

To include a "[" use "[[]]" and for "]" use "[)]]", e.g.,:

```
/index\%[[[]0[]]]
```

matches "index" "index[" "index[0" and "index[0]".

{not available when compiled without the `|+syntax|` feature}

```
& \&d \&x \&o \&u \&U E678
```

- `\&d123` Matches the character specified with a decimal number. Must be followed by a non-digit.
- `\&o40` Matches the character specified with an octal number up to `0o377`. Numbers below `0o40` must be followed by a non-octal digit or a non-digit.
- `\&x2a` Matches the character specified with up to two hexadecimal characters.
- `\&u20AC` Matches the character specified with up to four hexadecimal characters.
- `\&U1234abcd` Matches the character specified with up to eight hexadecimal characters, up to `0x7fffffff`

---

## 7. Ignoring case in a pattern /ignorecase

If the `'ignorecase'` option is on, the case of normal letters is ignored. `'smartcase'` can be set to ignore case when the pattern contains lowercase letters only.

```
& \c \C
```

When `"\c"` appears anywhere in the pattern, the whole pattern is handled like `'ignorecase'` is on. The actual value of `'ignorecase'` and `'smartcase'` is ignored. `"\C"` does the opposite: Force matching case for the whole pattern. {only Vim supports `\c` and `\C`}

Note that `'ignorecase'`, `"\c"` and `"\C"` are not used for the character classes.

Examples:

pattern	'ignorecase'	'smartcase'	matches
foo	off	-	foo
foo	on	-	foo Foo F00
Foo	on	off	foo Foo F00
Foo	on	on	Foo
\cfoo	-	-	foo Foo F00
foo\C	-	-	foo

Technical detail:

```
NL-used-for-NuL
```

`<NuL>` characters in the file are stored as `<NL>` in memory. In the display they are shown as `"^@"`. The translation is done when reading and writing files. To match a `<NuL>` with a search pattern you can just enter `CTRL-@` or `"CTRL-V 000"`. This is probably just what you expect. Internally the character is replaced with a `<NL>` in the search pattern. What is unusual is that typing `CTRL-V CTRL-J` also inserts a `<NL>`, thus also searches for a `<NuL>` in the file.

## CR-used-for-NL

When **'fileformat'** is "mac", <NL> characters in the file are stored as <CR> characters internally. In the text they are shown as "^J". Otherwise this works similar to the usage of <NL> for a <Nul>.

When working with expression evaluation, a <NL> character in the pattern matches a <NL> in the string. The use of "\n" (backslash n) to match a <NL> doesn't work there, it only works to match text in the buffer.

## pattern-multi-byte pattern-multibyte

Patterns will also work with multibyte characters, mostly as you would expect. But invalid bytes may cause trouble, a pattern with an invalid byte will probably never match.

---

## 8. Composing characters

## patterns-composing

### /\Z

When "\Z" appears anywhere in the pattern, all composing characters are ignored. Thus only the base characters need to match, the composing characters may be different and the number of composing characters may differ. Only relevant when **'encoding'** is "utf-8".

Exception: If the pattern starts with one or more composing characters, these must match.

### /\%C

Use "\%C" to skip any composing characters. For example, the pattern "a" does not match in "càt" (where the a has the composing character 0x0300), but "a\C" does. **Note** that this does not match "cát" (where the á is character 0xe1, it does not have a composing character). It does match "cat" (where the a is just an a).

When a composing character appears at the start of the pattern or after an item that doesn't include the composing character, a match is found at any character that includes this composing character.

When using a dot and a composing character, this works the same as the composing character by itself, except that it doesn't matter what comes before this.

The order of composing characters does not matter. Also, the text may have more composing characters than the pattern, it still matches. But all composing characters in the pattern must be found in the text.

Suppose B is a base character and x and y are composing characters:

pattern	text	match
Bxy	Bxy	yes (perfect match)
Bxy	Byx	yes (order ignored)
Bxy	By	no (x missing)
Bxy	Bx	no (y missing)
Bx	Bx	yes (perfect match)
Bx	By	no (x missing)
Bx	Bxy	yes (extra y ignored)
Bx	Byx	yes (extra y ignored)

---

## 9. Compare with Perl patterns

perl-patterns

Vim's regexes are most similar to Perl's, in terms of what you can do. The difference between them is mostly just notation; here's a summary of where they differ:

Capability	in Vimspeak	in Perlspeak
force case insensitivity	<code>\c</code>	<code>(?i)</code>
force case sensitivity	<code>\C</code>	<code>(?-i)</code>
backref-less grouping	<code>\%(atom\)</code>	<code>(?:atom)</code>
conservative quantifiers	<code>\{-n,m}</code>	<code>*?, +?, ??, {}?</code>
0-width match	<code>atom\@=</code>	<code>(?=atom)</code>
0-width non-match	<code>atom\@!</code>	<code>(?!atom)</code>
0-width preceding match	<code>atom\@&lt;=</code>	<code>(?&lt;=atom)</code>
0-width preceding non-match	<code>atom\@&lt;!</code>	<code>(?&lt;!atom)</code>
match without retry	<code>atom\@&gt;</code>	<code>(?&gt;atom)</code>

Vim and Perl handle newline characters inside a string a bit differently:

In Perl, `^` and `$` only match at the very beginning and end of the text, by default, but you can set the `'m'` flag, which lets them match at embedded newlines as well. You can also set the `'s'` flag, which causes a `.` to match newlines as well. (Both these flags can be changed inside a pattern using the same syntax used for the `i` flag above, BTW.)

On the other hand, Vim's `^` and `$` always match at embedded newlines, and you get two separate atoms, `\%^` and `\%$`, which only match at the very start and end of the text, respectively. Vim solves the second problem by giving you the `\_` "modifier": put it in front of a `.` or a character class, and they will match newlines as well.

Finally, these constructs are unique to Perl:

- execution of arbitrary code in the regex: `(?{perl code})`
- conditional expressions: `(?(condition>true-expr|false-expr)`

...and these are unique to Vim:

- changing the magic-ness of a pattern: `\v \V \m \M`  
(very useful for avoiding backslashitis)
- sequence of optionally matching atoms: `\%[atoms]`
- `\&` (which is to `\|` what "and" is to "or"; it forces several branches to match at one spot)
- matching lines/columns by number: `\%5l \%5c \%5v`
- setting the start and end of the match: `\zs \ze`

---

## 10. Highlighting matches

match-highlight

syntax-vs-match

**Note** that the match highlight mechanism is independent of [syntax-highlighting](#), which is (usually) a buffer-local highlighting, while matching is window-local, both methods

can be freely mixed. Match highlighting functions give you a bit more flexibility in when and how to apply, but are typically only used for temporary highlighting, without strict rules. Both methods can be used to conceal text.

Thus the matching functions like `matchadd()` won't consider syntax rules and functions like `synconcealed()` and the other way around.

```
 :mat :match
:mat[ch] {group} /{pattern}/
 Define a pattern to highlight in the current window. It will
 be highlighted with {group}. Example:
 :highlight MyGroup ctermbg=green guibg=green
 :match MyGroup /TODO/
```

Instead of // any character can be used to mark the start and end of the {pattern}. Watch out for using special characters, such as '"' and '|'.

{group} must exist at the moment this command is executed.

The {group} highlighting still applies when a character is to be highlighted for 'hlsearch', as the highlighting for matches is given higher priority than that of 'hlsearch'. Syntax highlighting (see 'syntax') is also overruled by matches.

**Note** that highlighting the last used search pattern with 'hlsearch' is used in all windows, while the pattern defined with ":match" only exists in the current window. It is kept when switching to another buffer.

'ignorecase' does not apply, use /\c in the pattern to ignore case. Otherwise case is not ignored.

'redrawtime' defines the maximum time searched for pattern matches.

When matching end-of-line and Vim redraws only part of the display you may get unexpected results. That is because Vim looks for a match in the line where redrawing starts.

Also see `matcharg()` and `getmatches()`. The former returns the highlight group and pattern of a previous `:match` command. The latter returns a list with highlight groups and patterns defined by both `matchadd()` and `:match`.

Highlighting matches using `:match` are limited to three matches (aside from `:match`, `:2match` and `:3match` are available). `matchadd()` does not have this limitation and in addition makes it possible to prioritize matches.

Another example, which highlights all characters in virtual column 72 and more:

```

:highlight rightMargin term=bold ctermfg=blue guifg=blue
:match rightMargin /.\.%>72v/
To highlight all character that are in virtual column 7:
:highlight col8 ctermbg=grey guibg=grey
:match col8 /\%<8v.\%>7v/

```

Note the use of two items to also match a character that occupies more than one virtual column, such as a TAB.

```

:mat[ch]
:mat[ch] none

```

Clear a previously defined match pattern.

```

:2mat[ch] {group} /{pattern}/ :2match
:2mat[ch]
:2mat[ch] none
:3mat[ch] {group} /{pattern}/ :3match
:3mat[ch]
:3mat[ch] none

```

Just like `:match` above, but set a separate match. Thus there can be three matches active at the same time. The match with the lowest number has priority if several match at the same position. It uses the match id 3. The `":3match"` command is used by (Vim < 9.0.2054) `matchparen` plugin. You are suggested to use `":match"` for manual matching and `":2match"` for another plugin or even better make use of the more flexible `matchadd()` (and similar) functions instead.

---

## 11. Fuzzy matching fuzzy-matching

Fuzzy matching refers to matching strings using a non-exact search string. Fuzzy matching will match a string, if all the characters in the search string are present anywhere in the string in the same order. Case is ignored. In a matched string, other characters can be present between two consecutive characters in the search string. If the search string has multiple words, then each word is matched separately. So the words in the search string can be present in any order in a string.

Fuzzy matching assigns a score for each matched string based on the following criteria:

- The number of sequentially matching characters.
- The number of characters (distance) between two consecutive matching characters.
- Matches at the beginning of a word
- Matches at a camel case character (e.g. Case in CamelCase)
- Matches after a path separator or a hyphen.
- The number of unmatched characters in a string.
- A full/exact match is preferred.

The matching string with the highest score is returned first.

For example, when you search for the "get pat" string using fuzzy matching, it will match the strings "GetPattern", "PatternGet", "getPattern", "patGetter", "getSomePattern", "MatchpatternGet" etc.

The functions `matchfuzzy()` and `matchfuzzypos()` can be used to fuzzy search a string in a List of strings. The `matchfuzzy()` function returns a List of matching strings. The `matchfuzzypos()` functions returns the List of matches, the matching positions and the fuzzy match scores.

The "f" flag of `:vimgrep` enables fuzzy matching.

To enable fuzzy matching for `ins-completion`, add the "fuzzy" value to the `'completeopt'` option.

## VIM REFERENCE MANUAL by Bram Moolenaar

Key mapping, abbreviations and user-defined commands.

This subject is introduced in sections 05.4 , 24.7 and 40.1 of the user manual.

1. Key mapping	key-mapping	
1.1 MAP COMMANDS		:map-commands
1.2 Special arguments		:map-arguments
1.3 Mapping and modes		:map-modes
1.4 Listing mappings		map-listing
1.5 Mapping special keys		:map-special-keys
1.6 Special characters		:map-special-chars
1.7 What keys to map		map-which-keys
1.8 Examples		map-examples
1.9 Using mappings		map-typing
1.10 Mapping alt-keys		:map-alt-keys
1.11 Mapping meta-keys		:map-meta-keys
1.12 Mapping super-keys or command keys		:map-super-keys
1.13 Mapping in modifyOtherKeys mode		modifyOtherKeys
1.14 Mapping with Kitty keyboard protocol		kitty-keyboard-protocol
1.15 Mapping an operator		:map-operator
2. Abbreviations	abbreviations	
3. Local mappings and functions	script-local	
4. User-defined commands	user-commands	

1. Key mapping	key-mapping	mapping	macro
----------------	-------------	---------	-------

Key mapping is used to change the meaning of typed keys. The most common use is to define a sequence of commands for a function key. Example:

```
:map <F2> a<C-R>=strftime("%c")<CR><Esc>
```

This appends the current date and time after the cursor (in <> notation <> ).

1.1 MAP COMMANDS	:map-commands
------------------	---------------

There are commands to enter new mappings, remove mappings and list mappings. See [map-overview](#) for the various forms of "map" and their relationships with modes.

{lhs} means left-hand-side  
{rhs} means right-hand-side

{lhs}  
{rhs}

:map	{lhs} {rhs}	mapmode-nvo	:map
:nm[ap]	{lhs} {rhs}	mapmode-n	:nm :nmap
:vm[ap]	{lhs} {rhs}	mapmode-v	:vm :vmap

:xm[ap]	{lhs} {rhs}	mapmode-x	:xm	:xmap
:smap	{lhs} {rhs}	mapmode-s		:smap
:om[ap]	{lhs} {rhs}	mapmode-o	:om	:omap
:map!	{lhs} {rhs}	mapmode-ic	:map!	
:im[ap]	{lhs} {rhs}	mapmode-i	:im	:imap
:lm[ap]	{lhs} {rhs}	mapmode-l	:lm	:lma :lmap
:cm[ap]	{lhs} {rhs}	mapmode-c	:cm	:cmap
:tma[p]	{lhs} {rhs}	mapmode-t	:tma	:tmap

Map the key sequence {lhs} to {rhs} for the modes where the map command applies. The result, including {rhs}, is then further scanned for mappings. This allows for nested and recursive use of mappings.

**Note:** Trailing spaces are included in the {rhs}, because space is a valid Normal mode command.

See [map-trailing-white](#) .

:no[remap]	{lhs} {rhs}	mapmode-nvo	:nore	:noremap	:nor
:nn[oremap]	{lhs} {rhs}	mapmode-n	:nn	:nnoremap	
:vn[oremap]	{lhs} {rhs}	mapmode-v	:vn	:vnoremap	
:xn[oremap]	{lhs} {rhs}	mapmode-x	:xn	:xnoremap	
:snor[emap]	{lhs} {rhs}	mapmode-s	:snor	:snore	:snoremap
:ono[remap]	{lhs} {rhs}	mapmode-o	:ono	:onoremap	
:no[remap]!	{lhs} {rhs}	mapmode-ic	:no!	:noremap!	
:ino[remap]	{lhs} {rhs}	mapmode-i	:ino	:inor	:inoremap
:ln[oremap]	{lhs} {rhs}	mapmode-l	:ln	:lnoremap	
:cno[remap]	{lhs} {rhs}	mapmode-c	:cno	:cnor	:cnoremap
:tno[remap]	{lhs} {rhs}	mapmode-t	:tno	:tnoremap	

Map the key sequence {lhs} to {rhs} for the modes where the map command applies. Disallow mapping of {rhs}, to avoid nested and recursive mappings. Often used to redefine a command.

**Note:** Keys in {rhs} also won't trigger abbreviation, with the exception of `i_CTRL-]` and `c_CTRL-]` .

**Note:** When `<Plug>` appears in the {rhs} this part is always applied even if remapping is disallowed.

:unm[ap]	{lhs}	mapmode-nvo	:unm	:unmap
:nun[map]	{lhs}	mapmode-n	:nun	:nunmap
:vu[nmap]	{lhs}	mapmode-v	:vu	:vunmap
:xu[nmap]	{lhs}	mapmode-x	:xu	:xunmap
:sunm[ap]	{lhs}	mapmode-s	:sunm	:sunmap
:ou[nmap]	{lhs}	mapmode-o	:ou	:ounmap
:unm[ap]!	{lhs}	mapmode-ic	:unm!	:unmap!
:iu[nmap]	{lhs}	mapmode-i	:iu	:iunmap
:lu[nmap]	{lhs}	mapmode-l	:lu	:lunmap
:cu[nmap]	{lhs}	mapmode-c	:cu	:cun :cunmap
:tunma[p]	{lhs}	mapmode-t	:tunma	:tunmap

Remove the mapping of {lhs} for the modes where the map command applies. The mapping may remain defined for other modes where it applies.

It also works when {lhs} matches the {rhs} of a mapping. This is for when an abbreviation applied.

**Note:** Trailing spaces are included in the `{lhs}`.  
See `map-trailing-white` .

<code>:mapc[lear]</code>	<code>mapmode-nvo</code>	<code>:mapc</code>	<code>:mapclear</code>
<code>:nmapc[lear]</code>	<code>mapmode-n</code>	<code>:nmapc</code>	<code>:nmapclear</code>

<code>:tma[p] {lhs}</code>	<code>mapmode-t</code>	<code>:tma_l</code>

List the key mappings for the key sequences starting with `{lhs}` in the modes where the map command applies.

These commands are used to map a key or key sequence to a string of characters. You can use this to put command sequences under function keys, translate one key into another, etc. See `:mkexrc` for how to save and restore the current mappings.

## map-ambiguous

When two mappings start with the same sequence of characters, they are ambiguous. Example:

```
:imap aa foo
:imap aaa bar
```

When Vim has read "aa", it will need to get another character to be able to decide if "aa" or "aaa" should be mapped. This means that after typing "aa" that mapping won't get expanded yet, Vim is waiting for another character. If you type a space, then "foo" will get inserted, plus the space. If you type "a", then "bar" will get inserted.

## Trailing white space

## map-trailing-white

This unmap command does NOT work:

```
:map @@ foo
:unmap @@ | print
```

Because it tries to unmap "@@ ", including the white space before the command separator "|". Other examples with trailing white space:

```
unmap @@
unmap @@ # Vim9 script comment
unmap @@ " legacy script comment
```

An error will be issued, which is very hard to identify, because the ending whitespace character in `unmap @@ ` is not visible.

A generic solution is to put the command separator "|" right after the mapped keys. After that white space and a comment may follow:

```
unmap @@| # Vim9 script comment
unmap @@| " legacy script comment
```

## 1.2 SPECIAL ARGUMENTS

## :map-arguments

"<buffer>", "<nowait>", "<silent>", "<special>", "<script>", "<expr>" and "<unique>" can be used in any order. They must appear right after the command, before any other arguments.

```
:map-local :map-<buffer> :map-buffer
E224 E225
```

If the first argument to one of these commands is "<buffer>" the mapping will be effective in the current buffer only. Example:

```
:map <buffer> ,w /[.,;]<CR>
```

Then you can map ",w" to something else in another buffer:

```
:map <buffer> ,w /[#&!]<CR>
```

The local buffer mappings are used before the global ones. See <nowait> below to make a short local mapping not taking effect when a longer global one exists.

The "<buffer>" argument can also be used to clear mappings:

```
:unmap <buffer> ,w
:mapclear <buffer>
```

Local mappings are also cleared when a buffer is deleted, but not when it is

unloaded. Just like local option values.  
Also see [map-precedence](#) .

`:map-<nowait>`    `:map-nowait`

When defining a buffer-local mapping for ",", there may be a global mapping that starts with ",". Then you need to type another character for Vim to know whether to use the "," mapping or the longer one. To avoid this add the `<nowait>` argument. Then the mapping will be used when it matches, Vim does not wait for more characters to be typed. However, if the characters were already typed they are used.

**Note** that this works when the `<nowait>` mapping fully matches and is found before any partial matches. This works when:

- There is only one matching buffer-local mapping, since these are always found before global mappings.
- There is another buffer-local mapping that partly matches, but it is defined earlier (last defined mapping is found first).

`:map-<silent>`    `:map-silent`

To define a mapping which will not be echoed on the command line, add "`<silent>`" as the first argument. Example:

```
:map <silent> ,h /Header<CR>
```

The search string will not be echoed when using this mapping. Messages from the executed command are still given though. To shut them up too, add a `":silent"` in the executed command:

```
:map <silent> ,h :exe ":silent normal /Header\r"<CR>
```

**Note** that the effect of a command might also be silenced, e.g., when the mapping selects another entry for command line completion it won't be displayed.

Prompts will still be given, e.g., for `inputdialog()`.

Using "`<silent>`" for an abbreviation is possible, but will cause redrawing of the command line to fail.

`:map-<special>`    `:map-special`

Define a mapping with `<>` notation for special keys, even though the "`<`" flag may appear in '`cptions`'. This is useful if the side effect of setting '`cptions`' is not desired. Example:

```
:map <special> <F12> /Header<CR>
```

`:map-<script>`    `:map-script`

If the first argument to one of these commands is "`<script>`" and it is used to define a new mapping or abbreviation, the mapping will only remap characters in the `{rhs}` using mappings that were defined local to a script, starting with "`<SID>`". This can be used to avoid that mappings from outside a script interfere (e.g., when **CTRL-V** is remapped in `mswin.vim`), but do use other mappings defined in the script.

**Note:** `":map <script>"` and `":noremap <script>"` do the same thing. The "`<script>`" overrules the command name. Using `":noremap <script>"` is preferred, because it's clearer that remapping is (mostly) disabled.

`:map-<unique>`    `:map-unique`    E226    E227

If the first argument to one of these commands is "`<unique>`" and it is used to define a new mapping or abbreviation, the command will fail if the mapping or abbreviation already exists. Example:

```
:map <unique> ,w /[#&!]<CR>
```

When defining a local mapping, there will also be a check if a global map already exists which is equal.

Example of what will fail:

```
:map ,w /[#&!]<CR>
:map <buffer> <unique> ,w /[,;]<CR>
```

If you want to map a key and then have it do what it was originally mapped to, have a look at `maparg()` .

If the first argument to one of these commands is "`<expr>`" and it is used to define a new mapping or abbreviation, the argument is an expression. The expression is evaluated to obtain the `{rhs}` that is used. Example:

```
:inoremap <expr> . <SID>InsertDot()
```

The result of the `s:InsertDot()` function will be inserted. It could check the text before the cursor and start omni completion when some condition is met. Using a script-local function is preferred, to avoid polluting the global namespace. Use `<SID>` in the RHS so that the script that the mapping was defined in can be found.

For abbreviations `v:char` is set to the character that was typed to trigger the abbreviation. You can use this to decide how to expand the `{lhs}`. You should not either insert or change the `v:char`.

In case you want the mapping to not do anything, you can have the expression evaluate to an empty string. If something changed that requires Vim to go through the main loop (e.g. to update the display), return "`\<Ignore>`". This is similar to "nothing" but makes Vim return from the loop that waits for input. Example:

```
func s:OpenPopup()
 call popup_create(... arguments ...)
 return "\<Ignore>"
endfunc
nnoremap <expr> <F3> <SID>OpenPopup()
```

Keep in mind that the expression may be evaluated when looking for typeahead, before the previous command has been executed. For example:

```
func StoreColumn()
 let g:column = col('.')
 return 'x'
endfunc
nnoremap <expr> x StoreColumn()
nmap ! f!x
```

You will notice that `g:column` has the value from before executing "f!", because "x" is evaluated before "f!" is executed.

This can be solved by inserting `<Ignore>` before the character that is expression-mapped:

```
nmap ! f!<Ignore>x
```

When defining a mapping in a `Vim9` script, the expression will be evaluated in the context of that script. This means that script-local items can be accessed in the expression.

Be very careful about side effects! The expression is evaluated while obtaining characters, you may very well make the command dysfunctional.

For this reason the following is blocked:

- Changing the buffer text `textlock` .
- Editing another buffer.
- The `:normal` command.
- Moving the cursor is allowed, but it is restored afterwards.

If you want the mapping to do any of these let the returned characters do that, or use a `<Cmd>` mapping instead.

You can use `getchar()`, it consumes typeahead if there is any. E.g., if you have these mappings:

```
inoremap <expr> <C-L> nr2char(getchar())
inoremap <expr> <C-L>x "foo"
```

If you now type **CTRL-L** nothing happens yet, Vim needs the next character to decide what mapping to use. If you type 'x' the second mapping is used and "foo" is inserted. If you type any other key the first mapping is used, `getchar()` gets the typed key and returns it.

Here is an example that inserts a list number that increases:

```
let counter = 0
inoremap <expr> <C-L> ListItem()
inoremap <expr> <C-R> ListReset()

func ListItem()
 let g:counter += 1
 return g:counter .. ' '
endfunc

func ListReset()
 let g:counter = 0
 return ''
endfunc
```

**CTRL-L** inserts the next number, **CTRL-R** resets the count. **CTRL-R** returns an empty string, so that nothing is inserted.

**Note** that using `0x80` as a single byte before other text does not work, it will be seen as a special key.

`<Cmd>` `:map-cmd`

The special text `<Cmd>` begins a "command mapping", it executes the command directly without changing modes. Where you might use `":...<CR>"` in the `{rhs}` of a mapping, you can instead use `"<Cmd>...<CR>"`.

Example:

```
noremap x <Cmd>echo mode(1)<CR>
```

This is more flexible than ``:<C-U>`` in Visual and Operator-pending mode, or ``<C-O>:`` in Insert mode, because the commands are executed directly in the current mode, instead of always going to Normal mode. Visual mode is preserved, so tricks with `gv` are not needed. Commands can be invoked directly in Command-line mode (which would otherwise require timer hacks).

Example of using `<Cmd>` halfway Insert mode:

```
nnoremap <F3> aText <Cmd>echo mode(1)<CR> Added<Esc>
```

Unlike `<expr>` mappings, there are no special restrictions on the `<Cmd>`

command: it is executed as if an (unrestricted) [autocommand](#) was invoked.

[<ScriptCmd>](#)

[<ScriptCmd>](#) is like [<Cmd>](#) but sets the context to the script the mapping was defined in, for the duration of the command execution. This is especially useful for [Vim9](#) script. It also works to access an import, which is useful in a plugin using a, possibly autoloaded, script:

```
vim9script
import autoload 'implementation.vim' as impl
nnoremap <F4> <ScriptCmd>impl.DoTheWork()<CR>
```

No matter where [<F4>](#) is typed, the "impl" import will be found in the script context of where the mapping was defined. When it's an autoload import, as in the example, the "implementation.vim" script will only be loaded once [<F4>](#) is typed, not when the mapping is defined.

Without [<ScriptCmd>](#) using "s:impl" would result in "E121: Undefined variable".

#### Note:

- Because [<Cmd>](#) and [<ScriptCmd>](#) avoid mode-changes it does not trigger [CmdlineEnter](#) and [CmdlineLeave](#) events, because no user interaction is expected.
- For the same reason, [keycodes](#) like [<C-R><C-W>](#) are interpreted as plain, unmapped keys.
- The command is not echo'ed, no need for [<silent>](#).
- The [{rhs}](#) is not subject to abbreviations nor to other mappings, even if the mapping is recursive.
- In Visual mode you can use ``line('v')`` and ``col('v')`` to get one end of the Visual area, the cursor is at the other end.

[E1255](#) [E1136](#)

[<Cmd>](#) and [<ScriptCmd>](#) commands must terminate, that is, they must be followed by [<CR>](#) in the [{rhs}](#) of the mapping definition. [Command-line](#) mode is never entered. To use a literal [<CR>](#) in the [{rhs}](#), use [<lt>](#) .

### 1.3 MAPPING AND MODES

[:map-modes](#)

[mapmode-nvo](#) [mapmode-n](#) [mapmode-v](#) [mapmode-o](#)

There are seven sets of mappings

- For Normal mode: When typing commands.
- For Visual mode: When typing commands while the Visual area is highlighted.
- For Select mode: like Visual mode but typing text replaces the selection.
- For Operator-pending mode: When an operator is pending (after "d", "y", "c", etc.). See below: [omap-info](#) .
- For Insert mode. These are also used in Replace mode.
- For Command-line mode: When entering a ":" or "/" command.
- For Terminal mode: When typing in a [:terminal](#) buffer.

Special case: While typing a count for a command in Normal mode, mapping zero is disabled. This makes it possible to map zero without making it impossible to type a count with a zero.

[map-overview](#) [map-modes](#)

Overview of which map command works in which mode. More details below.

COMMANDS			MODES
:map	:noremap	:unmap	Normal, Visual, Select, Operator-pending
:nmap	:nnoremap	:nunmap	Normal
:vmap	:vnoremap	:vunmap	Visual and Select
:smap	:snoremap	:sunmap	Select
:xmap	:xnoremap	:xunmap	Visual
:omap	:onoremap	:ounmap	Operator-pending
:map!	:noremap!	:unmap!	Insert and Command-line
:imap	:inoremap	:iunmap	Insert
:lmap	:lnoremap	:lunmap	Insert, Command-line, Lang-Arg
:cmap	:cnoremap	:cunmap	Command-line
:tmap	:tnoremap	:tunmap	Terminal-Job

Same information in a table:

Command	Mode	map-table							
		Norm	Ins	Cmd	Vis	Sel	Opr	Term	Lang
[nore]map		yes	-	-	yes	yes	yes	-	-
n[nore]map		yes	-	-	-	-	-	-	-
[nore]map!		-	yes	yes	-	-	-	-	-
i[nore]map		-	yes	-	-	-	-	-	-
c[nore]map		-	-	yes	-	-	-	-	-
v[nore]map		-	-	-	yes	yes	-	-	-
x[nore]map		-	-	-	yes	-	-	-	-
s[nore]map		-	-	-	-	yes	-	-	-
o[nore]map		-	-	-	-	-	yes	-	-
t[nore]map		-	-	-	-	-	-	yes	-
l[nore]map		-	yes	yes	-	-	-	-	yes

COMMANDS				MODES		
				Normal	Visual+Select	Operator-pending
:map	:noremap	:unmap	:mapclear	yes	yes	yes
:nmap	:nnoremap	:nunmap	:nmapclear	yes	-	-
:vmap	:vnoremap	:vunmap	:vmapclear	-	yes	-
:omap	:onoremap	:ounmap	:omapclear	-	-	yes

:nunmap can also be used outside of a monastery.

Some commands work both in Visual and Select mode, some in only one. [Note](#) that quite often "Visual" is mentioned where both Visual and Select mode apply. [Select-mode-mapping](#)

**NOTE:** Mapping a printable character in Select mode may confuse the user. It's better to explicitly use :xmap and :smap for printable characters. Or use :sunmap after defining the mapping.

COMMANDS				MODES					
				Visual	Select				
:vmap	:vnoremap	:vunmap	:vmapclear	yes	yes				
:xmap	:xnoremap	:xunmap	:xmapclear	yes	-				
:smap	:snoremap	:sunmap	:smapclear	-	yes				

[mapmode-ic](#)   [mapmode-i](#)   [mapmode-c](#)   [mapmode-l](#)

Some commands work both in Insert mode and Command-line mode, some not:

COMMANDS				MODES		
				Insert	Command-line	Lang-Arg
:map!	:noremap!	:unmap!	:mapclear!	yes	yes	-
:imap	:inoremap	:iunmap	:imapclear	yes	-	-
:cmap	:cnoremap	:cunmap	:cmapclear	-	yes	-
:lmap	:lnoremap	:lunmap	:lmapclear	yes*	yes*	yes*

\* If `'iminsert'` is 1, see [language-mapping](#) below.

The original Vi did not have separate mappings for Normal/Visual/Operator-pending mode and for Insert/Command-line mode. Therefore the `":map"` and `":map!"` commands enter and display mappings for several modes. In Vim you can use the `":nmap"`, `":vmap"`, `":omap"`, `":cmap"` and `":imap"` commands to enter mappings for each mode separately.

#### mapmode-t

The terminal mappings are used in a terminal window, when typing keys for the job running in the terminal. See [terminal-typing](#).

#### omap-info

Operator-pending mappings can be used to define a movement command that can be used with any operator. Simple example:

```
:omap { w
makes "y{" work like "yw" and "d{" like "dw".
```

To ignore the starting cursor position and select different text, you can have the `omap` start Visual mode to select the text to be operated upon. Example that operates on a function name in the current line:

```
onoremap <silent> F :<C-U>normal! @f(hv<CR>
```

The **CTRL-U** (<C-U>) is used to remove the range that Vim may insert. The Normal mode commands find the first '(' character and select the first word before it. That usually is the function name.

To enter a mapping for Normal and Visual mode, but not Operator-pending mode, first define it for all three modes, then unmap it for Operator-pending mode:

```
:map xx something-difficult
:ounmap xx
```

Likewise for a mapping for Visual and Operator-pending mode or Normal and Operator-pending mode.

#### language-mapping

`":lmap"` defines a mapping that applies to:

- Insert mode
- Command-line mode
- when entering a search pattern
- the argument of the commands that accept a text character, such as "r" and "f"
- for the `input()` line

Generally: Whenever a character is to be typed that is part of the text in the buffer, not a Vim command character. "Lang-Arg" isn't really another mode,

it's just used here for this situation.

The simplest way to load a set of related language mappings is by using the **'keymap'** option. See 45.5 .

In Insert mode and in Command-line mode the mappings can be disabled with the **CTRL-^** command `i_CTRL-^ c_CTRL-^` . These commands change the value of the **'iminsert'** option. When starting to enter a normal command line (not a search pattern) the mappings are disabled until a **CTRL-^** is typed. The state last used is remembered for Insert mode and Search patterns separately. The state for Insert mode is also used when typing a character as an argument to command like "f" or "t".

Language mappings will never be applied to already mapped characters. They are only used for typed characters. This assumes that the language mapping was already done when typing the mapping.

#### 1.4 LISTING MAPPINGS

**map-listing**

When listing mappings the characters in the first two columns are:

CHAR	MODE
<Space>	Normal, Visual, Select and Operator-pending
n	Normal
v	Visual and Select
s	Select
x	Visual
o	Operator-pending
!	Insert and Command-line
i	Insert
l	":lmap" mappings for Insert, Command-line and Lang-Arg
c	Command-line
t	Terminal-Job

Just before the `{rhs}` a special character can appear:

*	indicates that it is not remappable
&	indicates that only script-local mappings are remappable
@	indicates a buffer-local mapping

Everything from the first non-blank after `{lhs}` up to the end of the line (or '|') is considered to be part of `{rhs}`. This allows the `{rhs}` to end with a space.

**Note:** When using mappings for Visual mode, you can use the "<" mark, which is the start of the last selected Visual area in the current buffer '< .

The `:filter` command can be used to select what mappings to list. The pattern is matched against the `{lhs}` and `{rhs}` in the raw form.

While mappings are being listed, it is not possible to add or clear mappings, e.g. from a timer callback. **E1309**

**:map-verbose**

When **'verbose'** is non-zero, the detected and used **'keyprotocol'** value will be displayed in the first line. Also a key map will also display where it was last defined. Example:

```

:verbose map <C-W>*
Kitty keyboard protocol: Cleared
n <C-W>* * <C-W><C-S>*
 Last set from /home/abcd/.vimrc

```

See `:verbose-cmd` for more information.

## 1.5 MAPPING SPECIAL KEYS

`:map-special-keys`

There are three ways to map a special key:

1. The Vi-compatible method: Map the key code. Often this is a sequence that starts with `<Esc>`. To enter a mapping like this you type `:map "` and then you have to type **CTRL-V** before hitting the function key. **Note** that when the key code for the key is in the termcap (the `t_` options), it will automatically be translated into the internal code and become the second way of mapping (unless the `'k'` flag is included in `'coptions'`).
2. The second method is to use the internal code for the function key. To enter such a mapping type `CTRL-K` and then hit the function key, or use the form `"#1"`, `"#2"`, .. `"#9"`, `"#0"`, `"<Up>"`, `"<S-Down>"`, `"<S-F7>"`, etc. (see table of keys `key-notation`, all keys from `<Up>` can be used). The first ten function keys can be defined in two ways: Just the number, like `"#2"`, and with `"<F>"`, like `"<F2>"`. Both stand for function key 2. `"#0"` refers to function key 10, defined with option `'t_f10'`, which may be function key zero on some keyboards. The `<>` form cannot be used when `'coptions'` includes the `'<'` flag.
3. Use the termcap entry, with the form `<t_xx>`, where `"xx"` is the name of the termcap entry. Any string entry can be used. For example:

```

:map <t_F3> G

```

Maps function key 13 to "G". This does not work if `'coptions'` includes the `'<'` flag.

The advantage of the second and third method is that the mapping will work on different terminals without modification (the function key will be translated into the same internal code or the actual key code, no matter what terminal you are using. The termcap must be correct for this to work, and you must use the same mappings).

DETAIL: Vim first checks if a sequence from the keyboard is mapped. If it isn't the terminal key codes are tried (see `terminal-options`). If a terminal code is found it is replaced with the internal code. Then the check for a mapping is done again (so you can map an internal code to something else). What is written into the script file depends on what is recognized. If the terminal key code was recognized as a mapping the key code itself is written to the script file. If it was recognized as a terminal code the internal code is written to the script file.

## 1.6 SPECIAL CHARACTERS

`:map-special-chars`

`map_backslash` `map-backslash`

**Note** that only **CTRL-V** is mentioned here as a special character for mappings and abbreviations. When `'coptions'` does not contain `'B'`, a backslash can also be used like **CTRL-V**. The `<>` notation can be fully used then `<>`. But

you cannot use "<C-V>" like **CTRL-V** to escape the special meaning of what follows.

To map a backslash, or use a backslash literally in the {rhs}, the special sequence "<Bslash>" can be used. This avoids the need to double backslashes when using nested mappings.

map\_CTRL-C map-CTRL-C

Using **CTRL-C** in the {lhs} is possible, but it will only work when Vim is waiting for a key, not when Vim is busy with something. When Vim is busy **CTRL-C** interrupts/breaks the command.

When using the GUI version on MS-Windows **CTRL-C** can be mapped to allow a Copy command to the clipboard. Use **CTRL-Break** to interrupt Vim.

map\_space\_in\_lhs map-space\_in\_lhs

To include a space in {lhs} precede it with a **CTRL-V** (type two **CTRL-V**s for each space).

map\_space\_in\_rhs map-space\_in\_rhs

If you want a {rhs} that starts with a space, use "<Space>". To be fully Vi compatible (but unreadable) don't use the <> notation, precede {rhs} with a single **CTRL-V** (you have to type **CTRL-V** two times).

map\_empty\_rhs map-empty-rhs

You can create an empty {rhs} by typing nothing after a single **CTRL-V** (you have to type **CTRL-V** two times). Unfortunately, you cannot do this in a vimrc file.

<Nop>

An easier way to get a mapping that doesn't produce anything, is to use "<Nop>" for the {rhs}. This only works when the <> notation is enabled. For example, to make sure that function key 8 does nothing at all:

```
:map <F8> <Nop>
:map! <F8> <Nop>
```

map-multibyte

It is possible to map multibyte characters, but only the whole character. You cannot map the first byte only. This was done to prevent problems in this scenario:

```
:set encoding=latin1
:imap <M-C> foo
:set encoding=utf-8
```

The mapping for <M-C> is defined with the latin1 encoding, resulting in a 0xc3 byte. If you type the character á (0xe1 <M-a>) in UTF-8 encoding this is the two bytes 0xc3 0xa1. You don't want the 0xc3 byte to be mapped then or otherwise it would be impossible to type the á character.

<Leader> mapleader

To define a mapping which uses the "g:mapleader" variable, the special string "<Leader>" can be used. It is replaced with the string value of "g:mapleader". If "g:mapleader" is not set or empty, a backslash is used instead. Example:

```
map <Leader>A oanother line<Esc>
```

Works like:

```
map \A oanother line<Esc>
```

But after (legacy script):

```
let mapleader = ","
```

Or (Vim9 script):

```
g:mapleader = ","
```

It works like:

```
map ,A oanother line<Esc>
```

**Note** that the value of "g:mapleader" is used at the moment the mapping is defined. Changing "g:mapleader" after that has no effect for already defined mappings.

**<LocalLeader>** **maplocalleader**

**<LocalLeader>** is just like **<Leader>**, except that it uses "maplocalleader" instead of "mapleader". **<LocalLeader>** is to be used for mappings which are local to a buffer. Example:

```
:map <buffer> <LocalLeader>A oanother line<Esc>
```

In a global plugin **<Leader>** should be used and in a filetype plugin **<LocalLeader>**. "mapleader" and "maplocalleader" can be equal. Although, if you make them different, there is a smaller chance of mappings from global plugins to clash with mappings for filetype plugins. For example, you could keep "mapleader" at the default backslash, and set "maplocalleader" to an underscore.

**map-<SID>**

In a script the special key name "**<SID>**" can be used to define a mapping that's local to the script. See **<SID>** for details.

**<Plug>**

The special key name "**<Plug>**" can be used for an internal mapping, which is not to be matched with any key sequence. This is useful in plugins **using-<Plug>** .

**<MouseMove>**

The special key name "**<MouseMove>**" can be used to handle mouse movement. It needs to be enabled with '**mousemoveevent**'. Currently only works in the GUI. The **getmousepos()** function can be used to obtain the mouse position.

**<Char>** **<Char->**

To map a character by its decimal, octal or hexadecimal number the **<Char>** construct can be used:

```
<Char-123> character 123
<Char-033> character 27
<Char-0x7f> character 127
<S-Char-114> character 114 ('r') shifted ('R')
```

This is useful to specify a (multibyte) character in a '**keymap**' file. Upper and lowercase differences are ignored.

**map-comments**

It is not possible to put a comment after these commands, because the **'|'** character is considered to be part of the **{lhs}** or **{rhs}**. However, one can use **|**, since this starts a new, empty command with a comment.

**map\_bar** **map-bar**

Since the **'|'** character is used to separate a map command from the next command, you will have to do something special to include a **'|'** in **{rhs}**.

There are three methods:

use	works when	example
<Bar>	'<' is not in 'coptions'	:map _l :!ls <Bar> more^M
\	'b' is not in 'coptions'	:map _l :!ls \  more^M
^V	always, in Vim and Vi	:map _l :!ls ^V  more^M

(here ^V stands for **CTRL-V**; to get one **CTRL-V** you have to type it twice; you cannot use the <> notation "<C-V>" here).

All three work when you use the default setting for 'coptions'.

When 'b' is present in 'coptions', "\|" will be recognized as a mapping ending in a '\' and then another command. This is Vi compatible, but illogical when compared to other commands.

When you have a mapping that contains an Ex command, you need to put a line terminator after it to have it executed. The use of <CR> is recommended for this (see <> ). Example:

```
:map _ls :!ls -l %:S<CR>:echo "the end"<CR>
```

To avoid mapping of the characters you type in insert or Command-line mode, type a **CTRL-V** first. The mapping in Insert mode is disabled if the 'paste' option is on.

**Note** that when an error is encountered (that causes an error message or might cause a beep) the rest of the mapping is not executed. This is Vi-compatible.

**Note** that the second character (argument) of the commands @zZtTfF[ ]rm'`"v and **CTRL-X** is not mapped. This was done to be able to use all the named registers and marks, even when the command with the same name has been mapped.

## 1.7 WHAT KEYS TO MAP

If you are going to map something, you will need to choose which key(s) to use for the {lhs}. You will have to avoid keys that are used for Vim commands, otherwise you would not be able to use those commands anymore. Here are a few suggestions:

- Function keys <F2>, <F3>, etc.. Also the shifted function keys <S-F1>, <S-F2>, etc. **Note** that <F1> is already used for the help command.
- Any key with the Alt or Meta key pressed. Depending on your keyboard accented characters may be used as well. [:map-alt-keys](#)
- Use the '\_' or ',' character and then any other character. The "\_" and "," commands do exist in Vim (see \_ and , ), but you probably never use them.
- Use a key that is a synonym for another command. For example: **CTRL-P** and **CTRL-N**. Use an extra character to allow more mappings.
- The key defined by <Leader> and one or more other keys. This is especially useful in scripts. [mapleader](#)

See the file "index" for keys that are not used and thus can be mapped without losing any builtin function. You can also use ":help {key}^D" to find out if a key is used for some command. ({key} is the specific key you want to find

out about, ^D is **CTRL-D**).

## 1.8 EXAMPLES

map-examples

A few examples (given as you type them, for "<CR>" you type four characters; the '<' flag must not be present in '**coptions**' for this to work).

```
:map <F3> o#include
:map <M-g> /foo<CR>cwbar<Esc>
:map _x d/END/e<CR>
:map! qq quadrillion questions
```

### Multiplying a count

When you type a count before triggering a mapping, it's like the count was typed before the `{lhs}`. For example, with this mapping:

```
:map <F4> 3w
```

Typing 2<F4> will result in "23w". Thus not moving 2 \* 3 words but 23 words. If you want to multiply counts use the expression register:

```
:map <F4> @='3w'<CR>
```

The part between quotes is the expression being executed. @=

## 1.9 USING MAPPINGS

map-typing

Vim will compare what you type with the start of a mapped sequence. If there is an incomplete match, it will get more characters until there either is a complete match or until there is no match at all. Example: If you map! "qq", the first 'q' will not appear on the screen until you type another character. This is because Vim cannot know if the next character will be a 'q' or not. If the '**timeout**' option is on (which is the default) Vim will only wait for one second (or as long as specified with the '**timeoutlen**' option). After that it assumes that the 'q' is to be interpreted as such. If you type slowly, or your system is slow, reset the '**timeout**' option. Then you might want to set the '**ttimeout**' option.

map-precedence

Buffer-local mappings (defined using `:map-<buffer>`) take precedence over global mappings. When a buffer-local mapping is the same as a global mapping, Vim will use the buffer-local mapping. In addition, Vim will use a complete mapping immediately if it was defined with `<nowait>`, even if a longer mapping has the same prefix. For example, given the following two mappings:

```
:map <buffer> <nowait> \a :echo "Local \a"<CR>
:map \abc :echo "Global \abc"<CR>
```

When typing \a the buffer-local mapping will be used immediately. Vim will not wait for more characters to see if the user might be typing \abc.

map-keys-fails

There are situations where key codes might not be recognized:

- Vim can only read part of the key code. Mostly this is only the first character. This happens on some Unix versions in an xterm.
- The key code is after character(s) that are mapped. E.g., "<F1><F1>" or

"g<F1>".

The result is that the key code is not recognized in this situation, and the mapping fails. There are two actions needed to avoid this problem:

- Remove the 'K' flag from **'coptions'**. This will make Vim wait for the rest of the characters of the function key.
- When using <F1> to <F4> the actual key code generated may correspond to <xF1> to <xF4>. There are mappings from <xF1> to <F1>, <xF2> to <F2>, etc., but these are not recognized after another half a mapping. Make sure the key codes for <F1> to <F4> are correct:

```
:set <F1>=<type CTRL-V><type F1>
```

Type the <F1> as four characters. The part after the "=" must be done with the actual keys, not the literal text.

Another solution is to use the actual key code in the mapping for the second special key:

```
:map <F1><Esc>OP :echo "yes"<CR>
```

Don't type a real <Esc>, Vim will recognize the key code and replace it with <F1> anyway.

Another problem may be that when keeping ALT or Meta pressed the terminal prepends ESC instead of setting the 8th bit. See [:map-alt-keys](#) .

### recursive\_mapping

If you include the {lhs} in the {rhs} you have a recursive mapping. When {lhs} is typed, it will be replaced with {rhs}. When the {lhs} which is included in {rhs} is encountered it will be replaced with {rhs}, and so on. This makes it possible to repeat a command an infinite number of times. The only problem is that the only way to stop this is by causing an error. The macros to solve a maze uses this, look there for an example. There is one exception: If the {rhs} starts with {lhs}, the first character is not mapped again (this is Vi compatible).

For example:

```
:map ab abcd
```

will execute the "a" command and insert "bcd" in the text. The "ab" in the {rhs} will not be mapped again.

If you want to exchange the meaning of two keys you should use the `:noremap` command. For example:

```
:noremap k j
```

```
:noremap j k
```

This will exchange the cursor up and down commands.

With the normal `:map` command, when the **'remap'** option is on, mapping takes place until the text is found not to be a part of a {lhs}. For example, if you use:

```
:map x y
```

```
:map y x
```

Vim will replace x with y, and then y with x, etc. When this has happened **'maxmapdepth'** times (default 1000), Vim will give the error message "recursive mapping".

### :map-undo

If you include an undo command inside a mapped sequence, this will bring the

text back in the state before executing the macro. This is compatible with the original Vi, as long as there is only one undo command in the mapped sequence (having two undo commands in a mapped sequence did not make sense in the original Vi, you would get back the text before the first undo).

## 1.10 MAPPING ALT-KEYS

[:map-alt-keys](#)

For a readable mapping command the `<A-k>` form can be used. **Note** that `<A-k>` and `<A-K>` are different, the latter will use an upper case letter. Actually, `<A-K>` and `<A-S-K>` are the same. Instead of "A" you can use "M". If you have an actual Meta modifier key, please see [:map-meta-keys](#) .

In the GUI Vim handles the Alt key itself, thus mapping keys with ALT should always work. But in a terminal Vim gets a sequence of bytes and has to figure out whether ALT was pressed or not.

If the terminal supports the `modifyOtherKeys` mode and it has been enabled, then Vim can recognize more key combinations, see [modifyOtherKeys](#) below. The Kitty keyboard protocol works in a similar way, see [kitty-keyboard-protocol](#) .

By default Vim assumes that pressing the ALT key sets the 8th bit of a typed character. Most decent terminals can work that way, such as xterm, aterm and rxvt. If your `<A-k>` mappings don't work it might be that the terminal is prefixing the character with an ESC character. But you can just as well type ESC before a character, thus Vim doesn't know what happened (except for checking the delay between characters, which is not reliable).

As of this writing, some mainstream terminals like `gnome-terminal` and `konsole` use the ESC prefix. There doesn't appear a way to have them use the 8th bit instead. Xterm should work well by default. Aterm and rxvt should work well when started with the `--meta8` argument. You can also tweak resources like `metaSendsEscape`, `eightBitInput` and `eightBitOutput`.

On the Linux console, this behavior can be toggled with the `setmetamode` command. Bear in mind that not using an ESC prefix could get you in trouble with other programs. You should make sure that bash has the `convert-meta` option set to "on" in order for your Meta keybindings to still work on it (it's the default readline behavior, unless changed by specific system configuration). For that, you can add the line:

```
set convert-meta on
```

to your `~/.inputrc` file. If you're creating the file, you might want to use:

```
$include /etc/inputrc
```

as the first line, if that file exists on your system, to keep global options. This may cause a problem for entering special characters, such as the umlaut. Then you should use **CTRL-V** before that character.

Bear in mind that `convert-meta` has been reported to have troubles when used in UTF-8 locales. On terminals like xterm, the `metaSendsEscape` resource can be

toggled on the fly through the "Main Options" menu, by pressing Ctrl-LeftClick on the terminal; that's a good last resource in case you want to send ESC when using other applications but not when inside Vim.

### 1.11 MAPPING META-KEYS

`:map-meta-keys`

Mapping keys with the Meta modifier works very similar to using the Alt key. What key on your keyboard produces the Meta modifier depends on your keyboard and configuration.

**Note** that mapping `<M-a>` actually is for using the Alt key. That can be confusing! It cannot be changed, it would not be backwards compatible.

For the Meta modifier the "T" character is used. For example, to map Meta-b in Insert mode:

```
:imap <T-b> terrible
```

### 1.12 MAPPING SUPER-KEYS or COMMAND-KEYS

`:map-super-keys`    `:map-cmd-key`

The Super modifier is available in GUI mode (when `gui_running` is 1) for gVim on Linux and MacVim on Mac OS. If you're on a Mac, this represents the Command key, on Linux with the GTK GUI it represents the Super key. The character "D" is used for the Super / Command modifier.

For example, to map Command-b in Insert mode:

```
:imap <D-b> baritone
```

### 1.13 MAPPING IN modifyOtherKeys mode

`modifyOtherKeys`

Xterm and a few other terminals can be put in a mode where keys with modifiers are sent with a special escape code. Vim recognizes these codes and can then make a difference between **CTRL-H** and Backspace, even when Backspace sends the character 8. And many more special keys, such as Tab and **CTRL-I**, which cannot be mapped separately otherwise.

For xterm `modifyOtherKeys` is enabled in the builtin termcap entry. If this is not used you can enable `modifyOtherKeys` with these lines in your vimrc:

```
let &t_TI = "\<Esc>[>4;2m"
let &t_TE = "\<Esc>[>4;m"
```

This sets `modifyOtherKeys` to level 2. **Note** that `modifyOtherKeys` level 1 does not work. Some terminals do not support level 2 and then send key codes that Vim will not be able to correctly recognize.

In case the `modifyOtherKeys` mode causes problems you can disable it:

```
let &t_TI = ""
let &t_TE = ""
```

It does not take effect immediately. To have this work without restarting Vim execute a shell command, e.g.: ``!ls`` Or put the lines in your `vimrc`.

When `modifyOtherKeys` is enabled you can map `<C-[>` and `<C-S-{}>`:

```
imap <C-[> [[[
imap <C-{} {{{
```

Without `modifyOtherKeys` `<C-[>` and `<C-{}>` are indistinguishable from Esc. **Note** that `<C-{}>` is used and not `<C-S-[>` or `<C-S-{}>`. This works on most keyboards. Similarly, `<C-}>` is used instead of `<C-S-]>` or `<C-S-}>` and `<C-|>` instead of `<C-S-\>` or `<C-S-|>`. **Note** that `|` has a special meaning in a mapping, see `map-bar` .

**WARNING:** if you map `<C-[>` you may very well break any key codes that start with Esc. Make sure it comes AFTER other mappings.

Starting with xterm version 377 Vim can detect the `modifyOtherKeys` state by requesting it. For this the `'t_RK'` termcap entry is used. When the response is found then Vim will know whether `modifyOtherKeys` level 2 is enabled, and handle mappings accordingly.

Before version 377 Vim automatically detects if the `modifyOtherKeys` mode was enabled when it spots an escape sequence that must have been created by it. To see if Vim detected such an escape sequence use `verbose map`, the first line will then show "Seen `modifyOtherKeys`: true" (possibly translated).

This automatic detection depends on receiving an escape code starting with `<1b>[27;"`. This is the normal way xterm sends these key codes. However, if the `formatOtherKeys` resource is set another form is used that is not recognized, therefore you must not set `formatOtherKeys`.

A known side effect is that in Insert mode the raw escape sequence is inserted after the `CTRL-V` key. This can be used to check whether `modifyOtherKeys` is enabled: In Insert mode type `CTRL-SHIFT-V CTRL-V`, if you get one byte then `modifyOtherKeys` is off, if you get `<1b>[27;5;118~` then it is on.

**Note** that xterm up to version 376 has a bug that makes Shift-Esc send a regular Esc code, the Shift modifier is dropped.

When the `'esckeys'` option is off, then `modifyOtherKeys` will be disabled in Insert mode to avoid every key with a modifier causing Insert mode to end.

## 1.14 MAPPING WITH KITTY KEYBOARD PROTOCOL `kitty-keyboard-protocol`

If the value of `'term'` contains "kitty" then Vim will send out an escape sequence to enable the Kitty keyboard protocol. This can be changed with the `'keyprotocol'` option.

Like `modifyOtherKeys`, this will make it possible to distinguish between more keys with modifiers. Also, this protocol sends an escape sequence for the Esc key, so that Vim does not need to use a timeout to know whether receiving an Esc character means the Esc key was pressed or it's the start of an escape sequence.

Vim automatically detects if the Kitty keyboard protocol was enabled when it spots the response to the status request (this should be part of the `t_TI` termcap entry). To see if Vim detected such an escape sequence use:

```
:verbose map
```

The first line will then show "Kitty keyboard protocol: `{value}`" (possibly translated). The meaning of `{value}`:

Unknown	no status received yet
Off	protocol is not used
On	protocol is used
Disabled	protocol was used but expected to have been disabled by ' <b>t_TE</b> '
Cleared	protocol expected to have been disabled by ' <b>t_TE</b> ', previous state is unknown

### 1.15 MAPPING AN OPERATOR

**:map-operator**

An operator is used before a `{motion}` command. To define your own operator you must create a mapping that first sets the '**operatorfunc**' option and then invoke the `g@` operator. After the user types the `{motion}` command the specified function will be called.

`g@{motion}` Call the function set by the '**operatorfunc**' option. The '[' mark is positioned at the start of the text moved over by `{motion}`, the ']' mark on the last character of the text. The function is called with one String argument:

```

"line" {motion} was linewise
"char" {motion} was characterwise
"block" {motion} was blockwise-visual

```

The type can be forced, see **forced-motion**.  
{not available when compiled without the **+eval** feature}

Here is an example that counts the number of spaces with `<F4>`:

```

nnoremap <expr> <F4> CountSpaces()
xnoremap <expr> <F4> CountSpaces()
" doubling <F4> works on a line
nnoremap <expr> <F4><F4> CountSpaces() .. '_'

function CountSpaces(context = {}, type = '') abort
 if a:type == ''
 let context = #{
 \ dot_command: v:false,
 \ extend_block: '',
 \ virtualedit: [&:virtualedit, &g:virtualedit],
 \ }
 let &operatorfunc = function('CountSpaces', [context])
 set virtualedit=block
 return 'g@'
 endif

let save = #{
 \ clipboard: &clipboard,
 \ selection: &selection,
 \ virtualedit: [&:virtualedit, &g:virtualedit],
 \ register: getreginfo(''),
 \ visual_marks: [getpos("<">), getpos(">">)],

```

```

\ }

try
 set clipboard= selection=inclusive virtualedit=
 let commands = #{
 \ line: "'[V']",
 \ char: "`[v`]",
 \ block: "`[\<C-V>`]",
 \ }[a:type]
 let [_, _, col, off] = getpos("")
 if off != 0
 let vcol = getline("")->strpart(0, col + off)->strdisplaywidth()
 if vcol >= [line(""), '$']->virtcol() - 1
 let a:context.extend_block = '$'
 else
 let a:context.extend_block = vcol .. '|'
 endif
 endif
 if a:context.extend_block != ''
 let commands .= 'o0' .. a:context.extend_block
 endif
 let commands .= 'y'
 execute 'silent noautocmd keepjumps normal! ' .. commands
 echomsg getreg('')->count(' ')
finally
 call setreg('', save.register)
 call setpos('<', save.visual_marks[0])
 call setpos('>', save.visual_marks[1])
 let &clipboard = save.clipboard
 let &selection = save.selection
 let [&l:virtualedit, &g:virtualedit] = get(a:context.dot_command ? save : a:con
 let a:context.dot_command = v:true
endtry
endfunction

```

An `<expr>` mapping is used to be able to fetch any prefixed count and register. This also avoids using a command line, which would trigger `CmdlineEnter` and `CmdlineLeave` autocommands.

**Note** that the `'selection'` option is temporarily set to "inclusive" to be able to yank exactly the right text by using Visual mode from the `'[` to the `']` mark.

Also **note** that the `'clipboard'` option is temporarily emptied to avoid clobbering the ``"*`` or ``"+`` registers, if its value contains the item ``unnamed`` or ``unnamedplus``.

The ``mode()`` function will return the state as it will be after applying the operator.

Here is an example for using a lambda function to create a normal-mode operator to add quotes around text in the current line:

```
nnoremap <F4> <Cmd>let &opfunc='{t ->
```

```

\ getline(".")
\ ->split("\\zs")
\ ->insert("\'", col("'"']"))
\ ->insert("\'", col("'"'[") - 1)
\ ->join("")
\ ->setline(".")}'<CR>g@

```

---

## 2. Abbreviations

abbreviations    Abbreviations

Abbreviations are used in Insert mode, Replace mode and Command-line mode. If you enter a word that is an abbreviation, it is replaced with the word it stands for. This can be used to save typing for often used long words. And you can use it to automatically correct obvious spelling errors.

Examples:

```

:iab ms Microsoft
:iab tihs this

```

There are three types of abbreviations:

**full-id**    The "full-id" type consists entirely of keyword characters (letters and characters from '**iskeyword**' option). This is the most common abbreviation.

Examples: "foo", "g3", "-1"

**end-id**    The "end-id" type ends in a keyword character, but all the other characters are not keyword characters.

Examples: "#i", "..f", "\$/7"

**non-id**    The "non-id" type ends in a non-keyword character, the other characters may be of any type, excluding space and tab. {this type is not supported by Vi}

Examples: "def#", "4/7\$"

Examples of strings that cannot be abbreviations: "a.b", "#def", "a b", "\_\$r"

An abbreviation is only recognized when you type a non-keyword character. This can also be the <Esc> that ends Insert mode or the <CR> that ends a command. The non-keyword character which ends the abbreviation is inserted after the expanded abbreviation. An exception to this is the character <C-]>, which is used to expand an abbreviation without inserting any extra characters.

Example:

```

:ab hh hello
"hh<Space>" is expanded to "hello<Space>"
"hh<C-]>" is expanded to "hello"

```

The characters before the cursor must match the abbreviation. Each type has an additional rule:

- full-id In front of the match is a non-keyword character, or this is where the line or insertion starts. Exception: When the abbreviation is only one character, it is not recognized if there is a non-keyword character in front of it, other than a space or a tab. However, for the command line "'<,'>" (or any other marks) is ignored, as if the command line starts after it.
- end-id In front of the match is a keyword character, or a space or a tab, or this is where the line or insertion starts.
- non-id In front of the match is a space, tab or the start of the line or the insertion.

Examples: ({CURSOR} is where you type a non-keyword character)

```
:ab foo four old otters
 " foo{CURSOR}" is expanded to " four old otters"
 " foobar{CURSOR}" is not expanded
 "barfoo{CURSOR}" is not expanded

:ab #i #include
 "#i{CURSOR}" is expanded to "#include"
 ">#i{CURSOR}" is not expanded

:ab ;; <endofline>
 "test;;" is not expanded
 "test ;;" is expanded to "test <endofline>"
```

To avoid the abbreviation in Insert mode: Type **CTRL-V** before the character that would trigger the abbreviation. E.g. **CTRL-V** <Space>. Or type part of the abbreviation, exit insert mode with <Esc>, re-enter insert mode with "a" and type the rest.

To avoid the abbreviation in Command-line mode: Type **CTRL-V** twice somewhere in the abbreviation to avoid it to be replaced. A **CTRL-V** in front of a normal character is mostly ignored otherwise.

It is possible to move the cursor after an abbreviation:

```
:iab if if (<Left>
```

This does not work if '**coptions**' includes the '<' flag. <>

You can even do more complicated things. For example, to consume the space typed after an abbreviation:

```
func Eatchar(pat)
 let c = nr2char(getchar(0))
 return (c =~ a:pat) ? ' ' : c
endfunc
iabbr <silent> if if (<Left><C-R>=Eatchar('\s')<CR>
```

There are no default abbreviations.

Abbreviations are never recursive. You can use ":ab f f-o-o" without any problem. But abbreviations can be mapped. {some versions of Vi support recursive abbreviations, for no apparent reason}

Abbreviations are disabled if the **'paste'** option is on.

`:abbreviate-local` `:abbreviate-<buffer>`

Just like mappings, abbreviations can be local to a buffer. This is mostly used in a `filetype-plugin` file. Example for a C plugin file:

```
:abb <buffer> FF for (i = 0; i < ; ++i)
```

`:ab` `:abbreviate`

`:ab[breviate]` list all abbreviations. The character in the first column indicates the mode where the abbreviation is used: 'i' for insert mode, 'c' for Command-line mode, '!' for both. These are the same as for mappings, see `map-listing`.

`:abbreviate-verbose`

When **'verbose'** is non-zero, listing an abbreviation will also display where it was last defined. Example:

```
:verbose abbreviate
! teh the
Last set from /home/abcd/vim/abbr.vim
```

See `:verbose-cmd` for more information.

`:ab[breviate] {lhs}` list the abbreviations that start with `{lhs}`. You may need to insert a **CTRL-V** (type it twice) to avoid that a typed `{lhs}` is expanded, since command-line abbreviations apply here.

`:ab[breviate] [<expr>] [<buffer>] {lhs} {rhs}` add abbreviation for `{lhs}` to `{rhs}`. If `{lhs}` already existed it is replaced with the new `{rhs}`. `{rhs}` may contain spaces. See `:map-<expr>` for the optional `<expr>` argument. See `:map-<buffer>` for the optional `<buffer>` argument.

`:una` `:unabbreviate`

`:una[breviate] [<buffer>] {lhs}` Remove abbreviation for `{lhs}` from the list. If none is found, remove abbreviations in which `{lhs}` matches with the `{rhs}`. This is done so that you can even remove abbreviations after expansion. To avoid expansion insert a **CTRL-V** (type it twice).

`:norea` `:noreabbrev`

`:norea[bbrev] [<expr>] [<buffer>] [lhs] [rhs]` Same as `":ab"`, but no remapping for this `{rhs}`.

`:ca` `:cab` `:cabbrev`

`:ca[bbrev] [<expr>] [<buffer>] [lhs] [rhs]` Same as `":ab"`, but for Command-line mode only.

`:cuna` `:cunabbrev`

to be quoted. (Although quoting isn't harmful; that's why typing 7 [but not 8!] ^Vs works.)

Stored as: `esc      ^V^[`

After parsing, the abbreviation's short form ("esc") and long form (the two characters "^V^[") are stored in the abbreviation table. If you give the `:ab` command with no arguments, this is how the abbreviation will be displayed.

Later, when the abbreviation is expanded because the user typed in the word "esc", the long form is subjected to the same type of ^V interpretation as keyboard input. So the ^V protects the ^[ character from being interpreted as the "exit Insert mode" character. Instead, the ^[ is inserted into the text.

Expands to: `^[`

[example given by Steve Kirkendall]

---

### 3. Local mappings and functions

`script-local`

When using several Vim script files, there is the danger that mappings and functions used in one script use the same name as in other scripts. To avoid this, they can be made local to the script.

`<SID>`    `<SNR>`    `E81`

The string "`<SID>`" can be used in a mapping or menu. This requires that the '`<`' flag is not present in '`cpoptions`'. This is useful if you have a `script-local` function that you want to call from a mapping in the same script.

When executing the map command, Vim will replace "`<SID>`" with the special key code `<SNR>`, followed by a number that's unique for the script, and an underscore. Example:

```
:map <SID>Add
```

would define a mapping "`<SNR>23_Add`".

When defining a function in a script, "`s:`" can be prepended to the name to make it local to the script (in [Vim9](#) script functions without a prefix are local to the script). But when a mapping is executed from outside of the script, it doesn't know in which script the function was defined. To avoid this problem, use "`<SID>`" instead of "`s:`". The same translation is done as for mappings. This makes it possible to define a call to the function in a mapping.

When a local function is executed, it runs in the context of the script it was defined in. This means that new functions and mappings it defines can also use "`s:`" or "`<SID>`" and it will use the same unique number as when the function itself was defined. Also, the "`s:var`" local script variables can be used.

When executing an autocommand or a user command, it will run in the context of the script it was defined in. This makes it possible that the command calls a local function or uses a local mapping.

In case the value is used in a context where `<SID>` cannot be correctly expanded, use the `expand()` function:

```
let &includexpr = expand('<SID>') .. 'My_includeexpr()'
```

Otherwise, using "`<SID>`" outside of a script context is an error.

If you need to get the script number to use in a complicated script, you can use this function:

```
func s:ScriptNumber()
 return matchstr(expand('<SID>'), '<SNR>\zs\d\+\ze_')
endfunc
```

The "`<SNR>`" will be shown when listing functions and mappings. This is useful to find out what they are defined to.

The `:scriptnames` command can be used to see which scripts have been sourced and what their `<SNR>` number is.

This is all {not available when compiled without the `|+eval|` feature}.

---

#### 4. User-defined commands

user-commands

It is possible to define your own Ex commands. A user-defined command can act just like a built-in command (it can have a range or arguments, arguments can be completed as filenames or buffer names, etc), except that when the command is executed, it is transformed into a normal Ex command and then executed.

For starters: See section 40.2 in the user manual.

E183 E841 user-cmd-ambiguous

All user defined commands must start with an uppercase letter, to avoid confusion with builtin commands. Exceptions are these builtin commands:

```
:Next
:X
```

They cannot be used for a user defined command. `":Print"` is also an existing command, but it is deprecated and can be overruled.

The other characters of the user command can be uppercase letters, lowercase letters or digits. When using digits, **note** that other commands that take a numeric argument may become ambiguous. For example, the command `":Cc2"` could be the user command `":Cc2"` without an argument, or the command `":Cc"` with argument `"2"`. It is advised to put a space between the command name and the argument to avoid these problems.

When using a user-defined command, the command can be abbreviated. However, if an abbreviation is not unique, an error will be issued. Furthermore, a built-in command will always take precedence.

Example:

```
:command Rename ...
:command Renumber ...
:Rena " Means "Rename"
```

```

:Renu " Means "Re-number"
:Ren " Error - ambiguous
:command Paste ...
:P " The built-in :Print

```

It is recommended that full names for user-defined commands are used in scripts.

```

:com[mand] :com :command
 List all user-defined commands. When listing commands,
 the characters in the first columns are:
 ! Command has the -bang attribute
 " Command has the -register attribute
 | Command has the -bar attribute
 b Command is local to current buffer
 (see below for details on attributes)
 The list can be filtered on command name with
 :filter , e.g., to list all commands with "Pyth" in
 the name:
 filter Pyth command

```

```

:com[mand] {cmd} List the user-defined commands that start with {cmd}

```

:command-verbose

When **'verbose'** is non-zero, listing a command will also display where it was last defined and any completion argument. Example:

```

:verbose command TOhtml
 Name Args Range Complete Definition
 TOhtml 0 % :call Convert2HTML(<line1>, <line2>)
 Last set from /usr/share/vim/vim-7.0/plugin/tohtml.vim

```

See [:verbose-cmd](#) for more information.

E174 E182

```

:com[mand][!] [{attr}...] {cmd} {repl}
 Define a user command. The name of the command is
 {cmd} and its replacement text is {repl}. The
 command's attributes (see below) are {attr}. If the
 command already exists, an error is reported, unless a
 ! is specified, in which case the command is
 redefined. There is one exception: When sourcing a
 script again, a command that was previously defined in
 that script will be silently replaced.

```

```

:delc[ommand] {cmd} :delc :delcommand E184
 Delete the user-defined command {cmd}.
 This is not allowed while listing commands, e.g. from
 a timer. E1311

```

```

:delc[ommand] -buffer {cmd} E1237
 Delete the user-defined command {cmd} that was defined
 for the current buffer.

```

`:comc[lear]` `:comc` `:comclear`  
Delete all user-defined commands.

## Command attributes

`command-attributes`

User-defined commands are treated by Vim just like any other Ex commands. They can have arguments, or have a range specified. Arguments are subject to completion as filenames, buffers, etc. Exactly how this works depends upon the command's attributes, which are specified when the command is defined.

When defining a user command in a script, it will be able to call functions local to the script and use mappings local to the script. When the user invokes the user command, it will run in the context of the script it was defined in. This matters if `<SID>` is used in a command.

There are a number of attributes, split into four categories: argument handling, completion behavior, range handling, and special cases. The attributes are described below, by category.

## Argument handling

`E175` `E176` `:command-nargs`

By default, a user defined command will take no arguments (and an error is reported if any are supplied). However, it is possible to specify that the command can take arguments, using the `-nargs` attribute. Valid cases are:

<code>-nargs=0</code>	No arguments are allowed (the default)
<code>-nargs=1</code>	Exactly one argument is required, it includes spaces
<code>-nargs=*</code>	Any number of arguments are allowed (0, 1, or many), separated by white space
<code>-nargs=?</code>	0 or 1 arguments are allowed
<code>-nargs=+</code>	Arguments must be supplied, but any number are allowed

Arguments are considered to be separated by (unescaped) spaces or tabs in this context, except when there is one argument, then the white space is part of the argument.

**Note** that arguments are used as text, not as expressions. Specifically, `"s:var"` will use the script-local variable in the script where the command was defined, not where it is invoked! Example:

```
script1.vim:
 :let s:error = "None"
 :command -nargs=1 Error echoerr <args>
script2.vim:
 :source script1.vim
 :let s:error = "Wrong!"
 :Error s:error
```

Executing `script2.vim` will result in "None" being echoed. Not what you intended! Calling a function may be an alternative.

## Completion behavior

`:command-completion` E179 E180 E181  
`:command-complete`

By default, the arguments of user defined commands do not undergo completion. However, by specifying one or the other of the following attributes, argument completion can be enabled:

<code>-complete=arglist</code>	file names in argument list
<code>-complete=augroup</code>	autocmd groups
<code>-complete=behave</code>	<code>:behave</code> suboptions
<code>-complete=breakpoint</code>	<code>:breakadd</code> suboptions
<code>-complete=buffer</code>	buffer names
<code>-complete=color</code>	color schemes
<code>-complete=command</code>	Ex command (and arguments)
<code>-complete=compiler</code>	compilers
<code>-complete=cscope</code>	<code>:cscope</code> suboptions
<code>-complete=diff_buffer</code>	diff buffer names
<code>-complete=dir</code>	directory names
<code>-complete=dir_in_path</code>	directory names in <code>'cdpath'</code>
<code>-complete=environment</code>	environment variable names
<code>-complete=event</code>	autocommand events
<code>-complete=expression</code>	Vim expression
<code>-complete=file</code>	file and directory names
<code>-complete=file_in_path</code>	file and directory names in <code>'path'</code>
<code>-complete=filetype</code>	filetype names <code>'filetype'</code>
<code>-complete=function</code>	function name
<code>-complete=help</code>	help subjects
<code>-complete=highlight</code>	highlight groups
<code>-complete=history</code>	<code>:history</code> suboptions
<code>-complete=keymap</code>	keyboard mappings
<code>-complete=locale</code>	locale names (as output of <code>locale -a</code> )
<code>-complete=mapclear</code>	buffer argument
<code>-complete=mapping</code>	mapping name
<code>-complete=menu</code>	menus
<code>-complete=messages</code>	<code>:messages</code> suboptions
<code>-complete=option</code>	options
<code>-complete=packadd</code>	optional package <code>pack-add</code> names
<code>-complete=runtime</code>	file and directory names in <code>'runtimepath'</code>
<code>-complete=scriptnames</code>	sourced script names
<code>-complete=shellcmd</code>	Shell command
<code>-complete=shellcmdline</code>	First is a shell command and subsequent ones are filenames. The same behavior as <code>:!cmd</code>
<code>-complete=sign</code>	<code>:sign</code> suboptions
<code>-complete=syntax</code>	syntax file names <code>'syntax'</code>
<code>-complete=syntime</code>	<code>:syntime</code> suboptions
<code>-complete=tag</code>	tags
<code>-complete=tag_listfiles</code>	tags, file names are shown when <b>CTRL-D</b> is hit
<code>-complete=user</code>	user names
<code>-complete=var</code>	user variables
<code>-complete=custom,{func}</code>	custom completion, defined via <code>{func}</code>
<code>-complete=customlist,{func}</code>	custom completion, defined via <code>{func}</code>

If you specify completion while there is nothing to complete (`-nargs=0`, the default) then you get error `E1208` .

**Note:** That some completion methods might expand environment variables.

## Custom completion

```
:command-completion-custom
:command-completion-customlist E467 E468
```

It is possible to define customized completion schemes via the "custom,{func}" or the "customlist,{func}" completion argument. The {func} part should be a function with the following signature:

```
:function {func}(ArgLead, CmdLine, CursorPos)
```

The function need not use all these arguments. The function should provide the completion candidates as the return value.

For the "custom" argument, the function should return the completion candidates one per line in a newline separated string.

E1303

For the "customlist" argument, the function should return the completion candidates as a Vim List. Non-string items in the list are ignored.

The function arguments are:

ArgLead	the leading portion of the argument currently being completed on
CmdLine	the entire command line
CursorPos	the cursor position in it (byte index)

The function may use these for determining context. For the "custom" argument, it is not necessary to filter candidates against the (implicit pattern in) ArgLead. Vim will filter the candidates with its regexp engine after function return, and this is probably more efficient in most cases. If **'wildoptions'** contains "fuzzy", then the candidates will be filtered using **fuzzy-matching**. For the "customlist" argument, Vim will not filter the returned completion candidates and the user supplied function should filter the candidates.

The following example lists user names to a Finger command

```
:com -complete=custom,ListUsers -nargs=1 Finger !finger <args>
:fun ListUsers(A,L,P)
: return system("cut -d: -f1 /etc/passwd")
:endfun
```

The following example completes filenames from the directories specified in the **'path'** option:

```
:com -nargs=1 -bang -complete=customlist,EditFileComplete
 \ EditFile edit<bang> <args>
:fun EditFileComplete(A,L,P)
: return split(globpath(&path, a:A), "\n")
:endfun
```

This example does not work for file names with spaces!

## Range handling

```
E177 E178 :command-range :command-count
```

By default, user-defined commands do not accept a line number range. However,

it is possible to specify that the command does take a range (the `-range` attribute), or that it takes an arbitrary count value, either in the line number position (`-range=N`, like the `:split` command) or as a "count" argument (`-count=N`, like the `:Next` command). The count will then be available in the argument with `<count>` .

Possible attributes are:

<code>-range</code>	Range allowed, default is current line
<code>-range=%</code>	Range allowed, default is whole file (1,\$)
<code>-range=N</code>	A count (default N) which is specified in the line number position (like <code>:split</code> ); allows for zero line number.
<code>-count=N</code>	A count (default N) which is specified either in the line number position, or as an initial argument (like <code>:Next</code> ).
<code>-count</code>	Acts like <code>-count=0</code>

**Note** that `-range=N` and `-count=N` are mutually exclusive - only one should be specified.

#### `:command-addr`

It is possible that the special characters in the range like `.`, `$` or `%` which by default correspond to the current line, last line and the whole buffer, relate to arguments, (loaded) buffers, windows or tab pages.

Possible values are (second column is the short name used in listing):

<code>-addr=lines</code>		Range of lines (this is the default for <code>-range</code> )
<code>-addr=arguments</code>	<code>arg</code>	Range for arguments
<code>-addr=buffers</code>	<code>buf</code>	Range for buffers (also not loaded buffers)
<code>-addr=loaded_buffers</code>	<code>load</code>	Range for loaded buffers
<code>-addr=windows</code>	<code>win</code>	Range for windows
<code>-addr=tabs</code>	<code>tab</code>	Range for tab pages
<code>-addr=quickfix</code>	<code>qf</code>	Range for quickfix entries
<code>-addr=other</code>	<code>?</code>	Other kind of range; can use <code>."</code> , <code> "\$</code> and <code> "%</code> as with "lines" (this is the default for <code>-count</code> )

#### Special cases

`:command-bang`    `:command-bar`  
`:command-register`    `:command-buffer`  
`:command-keepscrip`

There are some special cases as well:

<code>-bang</code>	The command can take a <code>!</code> modifier (like <code>:q</code> or <code>:w</code> )
<code>-bar</code>	The command can be followed by a <code>" "</code> and another command. A <code>" "</code> inside the command argument is not allowed then. Also checks for a <code>"</code> to start a comment.
<code>-register</code>	The first argument to the command can be an optional register name (like <code>:del</code> , <code>:put</code> , <code>:yank</code> ).
<code>-buffer</code>	The command will only be available in the current buffer.
<code>-keepscrip</code>	Do not use the location of where the user command was defined for verbose messages, use the location of where the user command was invoked.

In the cases of the `-count` and `-register` attributes, if the optional argument is supplied, it is removed from the argument list and is available to the replacement text separately.

**Note** that these arguments can be abbreviated, but that is a deprecated feature. Use the full name for new scripts.

## Replacement text

`:command-repl`

The `{repl}` argument is normally one long string, possibly with `"|"` separated commands. A special case is when the argument is `"{"`, then the following lines, up to a line starting with `"}"` are used and `Vim9` syntax applies.

Example:

```
:command MyCommand {
 echo 'hello'
 g:calledMyCommand = true
}
```

`E1231`

There must be white space before the `"{"`. No nesting is supported, inline functions cannot be used. Commands where a `"|"` may appear in the argument, such as commands with an expression argument, cannot be followed by a `"|"` and another command.

If the command is defined in Vim9 script (a script that starts with ``:vim9script`` and in a ``:def`` function) then `{repl}` will be executed as in Vim9 script. Thus this depends on where the command is defined, not where it is used.

The replacement text `{repl}` for a user defined command is scanned for special escape sequences, using `<...>` notation. Escape sequences are replaced with values from the entered command line, and all other text is copied unchanged. The resulting string is executed as an Ex command. To avoid the replacement use `<lt>` in place of the initial `<`. Thus to include `"<bang>"` literally use `"<lt>bang"`.

The valid escape sequences are

- `<line1>` The starting line of the command range. `<line1>`
- `<line2>` The final line of the command range. `<line2>`
- `<range>` The number of items in the command range: 0, 1 or 2 `<range>`
- `<count>` Any count supplied (as described for the `'-range'` and `'-count'` attributes). `<count>`
- `<bang>` (See the `'-bang'` attribute) Expands to a `!` if the command was executed with a `!` modifier, otherwise expands to nothing. `<bang>`
- `<mods>` The command modifiers, if specified. Otherwise, expands to nothing. Supported modifiers are `:aboveleft`, `:belowright`, `<mods>` `<q-mods>` `:command-modifiers`

```

:botright , :browse , :confirm , :hide , :horizontal ,
:keepalt , :keepjumps , :keepmarks , :keeppatterns ,
:leftabove , :lockmarks , :noautocmd , :noswapfile ,
:rightbelow , :sandbox , :silent , :tab , :topleft ,
:unsilent , :verbose , and :vertical .

```

Note that `:filter` is not supported.

Examples:

```

command! -nargs=+ -complete=file MyEdit
 \ for f in expand(<q-args>, 0, 1) |
 \ exe '<mods> split ' .. f |
 \ endfor

function! SpecialEdit(files, mods)
 for f in expand(a:files, 0, 1)
 exe a:mods .. ' split ' .. f
 endfor
endfunction

command! -nargs=+ -complete=file Sedit
 \ call SpecialEdit(<q-args>, <q-mods>)

```

- `<reg>` (See the '-register' attribute) The optional register, if specified. Otherwise, expands to nothing. `<register>` is a synonym for this.
- `<args>` The command arguments, exactly as supplied (but as noted above, any count or register can consume some of the arguments, which are then not part of `<args>`).
- `<lt>` A single '<' (Less-Than) character. This is needed if you want to get a literal copy of one of these escape sequences into the expansion - for example, to get `<bang>`, use `<lt>bang<`.

`<q-args>`

If the first two characters of an escape sequence are "q-" (for example, `<q-args>`) then the value is quoted in such a way as to make it a valid value for use in an expression. This uses the argument as one single value. When there is no argument `<q-args>` is an empty string. See the `q-args-example` below.

`<f-args>`

To allow commands to pass their arguments on to a user-defined function, there is a special form `<f-args>` ("function args"). This splits the command arguments at spaces and tabs, quotes each argument individually, and the `<f-args>` sequence is replaced by the comma-separated list of quoted arguments. See the `Mycmd` example below. If no arguments are given `<f-args>` is removed.

To embed whitespace into an argument of `<f-args>`, prepend a backslash. `<f-args>` replaces every pair of backslashes (\\) with one backslash. A backslash followed by a character other than white space or a backslash remains unmodified. Also see `f-args-example` below. Overview:

<code>command</code>	<code>&lt;f-args&gt;</code>
XX ab	'ab'
XX a\b	'a\b'
XX a\ b	'a b'

```

XX a\ b 'a ', 'b'
XX a\\b 'a\b'
XX a\\ b 'a\ ', 'b'
XX a\\\b 'a\\b'
XX a\\\ b 'a\ b'
XX a\\\\b 'a\\b'
XX a\\\\ b 'a\\ ', 'b'
XX [nothing]

```

Note that if the "no arguments" situation is to be handled, you have to make sure that the function can be called without arguments. For a compiled function you might want to use variable arguments, see [vim9-variable-arguments](#) .

Examples for user commands:

```

" Delete everything after here to the end
:com Ddel +,$d

" Rename the current buffer
:com -nargs=1 -bang -complete=file Ren f <args>|w<bang>

" Replace a range with the contents of a file
" (Enter this all as one line)
:com -range -nargs=1 -complete=file
 Replace <line1>-pu_|<line1>,<line2>d|r <args>|<line1>d

" Count the number of lines in the range
:com! -range -nargs=0 Lines echo <line2> - <line1> + 1 "lines"

```

f-args-example

Call a user function (example of <f-args>)

```
:com -nargs=* Mycmd call Myfunc(<f-args>)
```

When executed as:

```
:Mycmd arg1 arg2
```

This will invoke:

```
:call Myfunc("arg1","arg2")
```

q-args-example

A more substantial example:

```

:function Allargs(command)
: let i = 0
: while i < argc()
: if filereadable(argv(i))
: execute "e " .. argv(i)
: execute a:command
: endif
: let i = i + 1
: endwhile
:endfunction
:command -nargs+= -complete=command Allargs call Allargs(<q-args>)

```

The command Allargs takes any Vim command(s) as argument and executes it on all files in the argument list. Usage example (note use of the "e" flag to ignore errors and the "update" command to write modified buffers):

```
:Allargs %s/foo/bar/ge|update
```

This will invoke:

```
:call Allargs("%s/foo/bar/ge|update")
```

Tags and special searches

tags-and-searches

See section 29.1 of the user manual for an introduction.

- 1. Jump to a tag [tag-commands](#)
- 2. Tag stack [tag-stack](#)
- 3. Tag match list [tag-matchlist](#)
- 4. Tags details [tag-details](#)
- 5. Tags file format [tags-file-format](#)
- 6. Include file searches [include-search](#)
- 7. Using 'tagfunc' [tag-function](#)

1. Jump to a tag

tag-commands

tag tags

A tag is an identifier that appears in a "tags" file. It is a sort of label that can be jumped to. For example: In C programs each function name can be used as a tag. The "tags" file has to be generated by a program like ctags, before the tag commands can be used.

With the ":tag" command the cursor will be positioned on the tag. With the CTRL-] command, the keyword on which the cursor is standing is used as the tag. If the cursor is not on a keyword, the first keyword to the right of the cursor is used.

The ":tag" command works very well for C programs. If you see a call to a function and wonder what that function does, position the cursor inside of the function name and hit CTRL-]. This will bring you to the function definition. An easy way back is with the CTRL-T command. Also read about the tag stack below.

:ta :tag E426 E429

:[count]ta[g][!] {name}

Jump to the definition of {name}, using the information in the tags file(s). Put {name} in the tag stack. See tag-! for [!]. {name} can be a regexp pattern, see tag-regexp . When there are several matching tags for {name}, jump to the [count] one. When [count] is omitted the first one is jumped to. See tag-matchlist for jumping to other matching tags.

g<LeftMouse>  
<C-LeftMouse>  
CTRL-]

g<LeftMouse>  
<C-LeftMouse> CTRL-]

Jump to the definition of the keyword under the cursor. Same as ":tag {name}", where {name} is the keyword under or after cursor.

When there are several matching tags for {name}, jump to the [count] one. When no [count] is given the first one is jumped to. See [tag-matchlist](#) for jumping to other matching tags.

**{Visual}CTRL-]** v\_CTRL-]  
Same as ":tag {name}", where {name} is the text that is highlighted.

**CTRL-]** telnet-CTRL-]  
is the default telnet escape key. When you type **CTRL-]** to jump to a tag, you will get the telnet prompt instead. Most versions of telnet allow changing or disabling the default escape key. See the telnet man page. You can 'telnet -E {Hostname}' to disable the escape character, or 'telnet -e {EscapeCharacter} {Hostname}' to specify another escape character. If possible, try to use "ssh" instead of "telnet" to avoid this problem.

tag-priority  
When there are multiple matches for a tag, this priority is used:

1. "FSC" A full matching static tag for the current file.
2. "F C" A full matching global tag for the current file.
3. "F " A full matching global tag for another file.
4. "FS " A full matching static tag for another file.
5. " SC" An ignore-case matching static tag for the current file.
6. " C" An ignore-case matching global tag for the current file.
7. " " An ignore-case matching global tag for another file.
8. " S " An ignore-case matching static tag for another file.

**Note** that when the current file changes, the priority list is mostly not changed, to avoid confusion when using ":tnext". It is changed when using ":tag {name}".

The ignore-case matches are not found for a ":tag" command when:

- 'tagcase' is "followic" and the 'ignorecase' option is off
- 'tagcase' is "followscs" and the 'ignorecase' option is off and the 'smartcase' option is off or the pattern contains an upper case character.
- 'tagcase' is "match"
- 'tagcase' is "smart" and the pattern contains an upper case character.

The ignore-case matches are found when:

- a pattern is used (starting with a "/"
- for ":tselect"
- when 'tagcase' is "followic" and 'ignorecase' is on
- when 'tagcase' is "followscs" and 'ignorecase' is on or the 'smartcase' option is on and the pattern does not contain an upper case character
- when 'tagcase' is "ignore"
- when 'tagcase' is "smart" and the pattern does not contain an upper case character

**Note** that using ignore-case tag searching disables binary searching in the tags file, which causes a slowdown. This can be avoided by fold-case sorting the tag file. See the 'tagbsearch' option for an explanation.

=====

## 2. Tag stack

tag-stack tagstack E425

On the tag stack is remembered which tags you jumped to, and from where. Tags are only pushed onto the stack when the '**tagstack**' option is set.

<code>g&lt;RightMouse&gt;</code>	<code>g&lt;RightMouse&gt;</code>
<code>&lt;C-RightMouse&gt;</code>	<code>&lt;C-RightMouse&gt;</code> <code>CTRL-T</code>
<b>CTRL-T</b>	Jump to <code>[count]</code> older entry in the tag stack (default 1).
<code>:[count]po[p][!]</code>	<code>:po</code> <code>:pop</code> <code>E555</code> <code>E556</code> Jump to <code>[count]</code> older entry in tag stack (default 1). See <code>tag-!</code> for <code>[!]</code> .
<code>:[count]ta[g][!]</code>	Jump to <code>[count]</code> newer entry in tag stack (default 1). See <code>tag-!</code> for <code>[!]</code> .
<code>:tags</code>	<code>:tags</code> Show the contents of the tag stack. The active entry is marked with a '>'. 

The output of `":tags"` looks like this:

```
T0 tag FROM line in file/text
1 1 main 1 harddisk2:text/vim/test
> 2 2 FuncA 58 i = FuncA(10);
3 1 FuncC 357 harddisk2:text/vim/src/amiga.c
```

This list shows the tags that you jumped to and the cursor position before that jump. The older tags are at the top, the newer at the bottom.

The '>' points to the active entry. This is the tag that will be used by the next `":tag"` command. The **CTRL-T** and `":pop"` command will use the position above the active entry.

Below the "T0" is the number of the current match in the match list. [Note](#) that this doesn't change when using `":pop"` or `":tag"`.

The line number and file name are remembered to be able to get back to where you were before the tag command. The line number will be correct, also when deleting/inserting lines, unless this was done by another program (e.g. another instance of Vim).

For the current file, the "file/text" column shows the text at the position. An indent is removed and a long line is truncated to fit in the window.

You can jump to previously used tags with several commands. Some examples:

<code>":pop"</code> or <b>CTRL-T</b>	to position before previous tag
<code>{count}CTRL-T</code>	to position before <code>{count}</code> older tag
<code>":tag"</code>	to newer tag
<code>":0tag"</code>	to last used tag

The most obvious way to use this is while browsing through the call graph of

a program. Consider the following call graph:

```
main ---> FuncA ---> FuncC
 ---> FuncB
```

(Explanation: main calls FuncA and FuncB; FuncA calls FuncC). You can get from main to FuncA by using **CTRL-]** on the call to FuncA. Then you can **CTRL-]** to get to FuncC. If you now want to go back to main you can use **CTRL-T** twice. Then you can **CTRL-]** to FuncB.

If you issue a `":ta {name}"` or **CTRL-]** command, this tag is inserted at the current position in the stack. If the stack was full (it can hold up to 20 entries), the oldest entry is deleted and the older entries shift one position up (their index number is decremented by one). If the last used entry was not at the bottom, the entries below the last used one are deleted. This means that an old branch in the call graph is lost. After the commands explained above the tag stack will look like this:

```
TO tag FROM line in file/text
1 1 main 1 harddisk2:text/vim/test
2 1 FuncB 59 harddisk2:text/vim/src/main.c
```

The `gettagstack()` function returns the tag stack of a specified window. The `settagstack()` function modifies the tag stack of a window.

#### tagstack-examples

Write to the tag stack just like `':tag'` but with a user-defined `jumper#jump_to_tag` function:

```
" Store where we're jumping from before we jump.
let tag = expand('<cword>')
let pos = [bufnr()] + getcurpos()[1:]
let item = {'bufnr': pos[0], 'from': pos, 'tagname': tag}
if jumper#jump_to_tag(tag)
 " Jump was successful, write previous location to tag stack.
 let winid = win_getid()
 let stack = gettagstack(winid)
 let stack['items'] = [item]
 call settagstack(winid, stack, 't')
endif
```

Set current index of the tag stack to 4:

```
call settagstack(1005, {'curidx' : 4})
```

Push a new item onto the tag stack:

```
let pos = [bufnr('myfile.txt'), 10, 1, 0]
let newtag = [{'tagname' : 'mytag', 'from' : pos}]
call settagstack(2, {'items' : newtag}, 'a')
```

#### E73

When you try to use the tag stack while it doesn't contain anything you will get an error message.

=====  
3. Tag match list

tag-matchlist E427 E428

When there are several matching tags, these commands can be used to jump between them. **Note** that these commands don't change the tag stack, they keep the same entry.

`:ts[elect][!] [name]` `:ts` `:tselect`  
List the tags that match `[name]`, using the information in the tags file(s).  
When `[name]` is not given, the last tag name from the tag stack is used.  
See `tag-!` for `[!]`.  
With a `'>'` in the first column is indicated which is the current position in the list (if there is one).  
`[name]` can be a regexp pattern, see `tag-regexp`.  
See `tag-priority` for the priorities used in the listing.  
Example output:

```
pri kind tag file
1 F f mch_delay os_amiga.c
 mch_delay(msec, ignoreinput)
> 2 F f mch_delay os_msdos.c
 mch_delay(msec, ignoreinput)
3 F f mch_delay os_unix.c
 mch_delay(msec, ignoreinput)
Type number and <Enter> (empty cancels):
```

See `tag-priority` for the "pri" column. **Note** that this depends on the current file, thus using `":tselect xxx"` can produce different results.  
The "kind" column gives the kind of tag, if this was included in the tags file.  
The "info" column shows information that could be found in the tags file. It depends on the program that produced the tags file.  
When the list is long, you may get the `more-prompt`.  
If you already see the tag you want to use, you can type 'q' and enter the number.

`:sts[elect][!] [name]` `:sts` `:stselect`  
Does `":tselect[!] [name]"` and splits the window for the selected tag.

`g]` `g]`  
Like **CTRL-]**, but use `":tselect"` instead of `":tag"`.

`{Visual}g]` `v_g]`  
Same as `"g]"`, but use the highlighted text as the identifier.

`:tj[ump][!] [name]` `:tj` `:tjump`  
Like `":tselect"`, but jump to the tag directly when there is only one match.

<code>:stj[ump][!] [name]</code>	Does <code>":tjump[!] [name]"</code> and splits the window for the selected tag.	<code>:stj</code> <code>:stjump</code>
<code>g CTRL-]</code>	Like <code>CTRL-]</code> , but use <code>":tjump"</code> instead of <code>":tag"</code> .	<code>g_CTRL-]</code>
<code>{Visual}g CTRL-]</code>	Same as <code>"g CTRL-]"</code> , but use the highlighted text as the identifier.	<code>v_g_CTRL-]</code>
<code>:[count]tn[ext][!]</code>	Jump to <code>[count]</code> next matching tag (default 1). See <code>tag-!</code> for <code>[!]</code> .	<code>:tn</code> <code>:tnext</code>
<code>:[count]tp[revious][!]</code>	Jump to <code>[count]</code> previous matching tag (default 1). See <code>tag-!</code> for <code>[!]</code> .	<code>:tp</code> <code>:tprevious</code>
<code>:[count]tN[ext][!]</code>	Same as <code>":tprevious"</code> .	<code>:tN</code> <code>:tNext</code>
<code>:[count]tr[ewind][!]</code>	Jump to first matching tag. If <code>[count]</code> is given, jump to <code>[count]</code> th matching tag. See <code>tag-!</code> for <code>[!]</code> .	<code>:tr</code> <code>:trewind</code>
<code>:[count]tf[irst][!]</code>	Same as <code>":trewind"</code> .	<code>:tf</code> <code>:tfirst</code>
<code>:tl[ast][!]</code>	Jump to last matching tag. See <code>tag-!</code> for <code>[!]</code> .	<code>:tl</code> <code>:tlast</code>
<code>:lt[ag][!] [name]</code>	Jump to tag <code>[name]</code> and add the matching tags to a new location list for the current window. <code>[name]</code> can be a regexp pattern, see <code>tag-regexp</code> . When <code>[name]</code> is not given, the last tag name from the tag stack is used. The search pattern to locate the tag line is prefixed with <code>"\V"</code> to escape all the special characters (very nomagic). The location list showing the matching tags is independent of the tag stack. See <code>tag-!</code> for <code>[!]</code> .	<code>:lt</code> <code>:ltag</code>

When there is no other message, Vim shows which matching tag has been jumped to, and the number of matching tags:

`tag 1 of 3 or more`

The " or more" is used to indicate that Vim didn't try all the tags files yet. When using `":tnext"` a few times, or with `":tlast"`, more matches may be found.

When you didn't see this message because of some other message, or you just want to know where you are, this command will show it again (and jump to the same tag as last time):

`:0tn`

### tag-skip-file

When a matching tag is found for which the file doesn't exist, this match is skipped and the next matching tag is used. Vim reports this, to notify you of missing files. When the end of the list of matches has been reached, an error message is given.

### tag-preview

The tag match list can also be used in the preview window. The commands are the same as above, with a "p" prepended.

{not available when compiled without the |+quickfix| feature}

### :pts :ptselect

`:pts[elect][!] [name]` Does `:tselect[!] [name]` and shows the new tag in a "Preview" window. See `:ptag` for more info.

### :ptj :ptjump

`:ptj[ump][!] [name]` Does `:tjump[!] [name]` and shows the new tag in a "Preview" window. See `:ptag` for more info.

### :ptn :ptnext

`:[count]ptn[ext][!]` `":tnext"` in the preview window. See `:ptag` .

### :ptp :ptprevious

`:[count]ptp[revious][!]` `":tprevious"` in the preview window. See `:ptag` .

### :ptN :ptNext

`:[count]ptN[ext][!]` Same as `":ptprevious"`.

### :ptr :ptrewind

`:[count]ptr[ewind][!]` `":trewind"` in the preview window. See `:ptag` .

### :ptf :ptfirst

`:[count]ptf[irst][!]` Same as `":ptrewind"`.

### :ptl :ptlast

`:ptl[ast][!]` `":tlast"` in the preview window. See `:ptag` .

---

## 4. Tags details

### tag-details

#### static-tag

A static tag is a tag that is defined for a specific file. In a C program this could be a static function.

In Vi jumping to a tag sets the current search pattern. This means that the "n" command after jumping to a tag does not search for the same pattern that it did before jumping to the tag. Vim does not do this as we consider it to be a bug. If you really want the old Vi behavior, set the 't' flag in **'coptions'**.

#### tag-binary-search

Vim uses binary searching in the tags file to find the desired tag quickly (when enabled at compile time `+tag_binary` ). But this only works if the

tags file was sorted on ASCII byte value. Therefore, if no match was found, another try is done with a linear search. If you only want the linear search, reset the **'tagbsearch'** option. Or better: Sort the tags file!

**Note** that the binary searching is disabled when not looking for a tag with a specific name. This happens when ignoring case and when a regular expression is used that doesn't start with a fixed string. Tag searching can be a lot slower then. The former can be avoided by case-fold sorting the tags file. See **'tagbsearch'** for details.

### tag-regex

The `":tag"` and `":tselect"` commands accept a regular expression argument. See **pattern** for the special characters that can be used.

When the argument starts with `'/'`, it is used as a pattern. If the argument does not start with `'/'`, it is taken literally, as a full tag name.

Examples:

- `:tag main`  
jumps to the tag "main" that has the highest priority.
- `:tag /^get`  
jumps to the tag that starts with "get" and has the highest priority.
- `:tag /norm`  
lists all the tags that contain "norm", including "id\_norm".

When the argument both exists literally, and match when used as a regexp, a literal match has a higher priority. For example, `":tag /open"` matches "open" before "open\_file" and "file\_open".

When using a pattern case is ignored. If you want to match case use `"\C"` in the pattern.

### tag-!

If the tag is in the current file this will always work. Otherwise the performed actions depend on whether the current file was changed, whether a `!` is added to the command and on the **'autowrite'** and **'winfixbuf'** options:

tag in current file	file changed	! !	winfixbuf option	autowrite option	action
yes	x	x	off	x	goto tag
no	no	x	off	x	read other file, goto tag
no	yes	yes	off	x	abandon current file, read other file, goto tag
no	yes	no	off	on	write current file, read other file, goto tag
no	yes	no	off	off	fail
yes	x	yes	x	x	goto tag
no	no	no	on	x	fail
no	yes	no	on	x	fail
no	yes	no	on	on	fail
no	yes	no	on	off	fail

- If the tag is in the current file, the command will always work.
- If the tag is in another file and the current file was not changed, the other file will be made the current file and read into the buffer.
- If the tag is in another file, the current file was changed and a `!` is

- added to the command, the changes to the current file are lost, the other file will be made the current file and read into the buffer.
- If the tag is in another file, the current file was changed and the **'autowrite'** option is on, the current file will be written, the other file will be made the current file and read into the buffer.
  - If the tag is in another file, the current file was changed and the **'autowrite'** option is off, the command will fail. If you want to save the changes, use the **":w"** command and then use **":tag"** without an argument. This works because the tag is put on the stack anyway. If you want to lose the changes you can use the **":tag!"** command.
  - If the tag is in another file and the window includes **'winfixbuf'**, the command will fail. If the tag is in the same file then it may succeed.

#### tag-security

**Note** that Vim forbids some commands, for security reasons. This works like using the **'secure'** option for `exrc/vimrc` files in the current directory. See [trojan-horse](#) and [sandbox](#).

When the `{tagaddress}` changes a buffer, you will get a warning message:

```
"WARNING: tag command changed a buffer!!!"
```

In a future version changing the buffer will be impossible. All this for security reasons: Somebody might hide a nasty command in the tags file, which would otherwise go unnoticed. Example:

```
:$d|/tag-function-name/
```

In Vi the **":tag"** command sets the last search pattern when the tag is searched for. In Vim this is not done, the previous search pattern is still remembered, unless the **'t'** flag is present in **'coptions'**.

#### emacs-tags emacs\_tags E430

Emacs style tag files are only supported if Vim was compiled with the **+emacs\_tags** feature enabled. Sorry, there is no explanation about Emacs tag files here, it is only supported for backwards compatibility :-).

Lines in Emacs tags files can be very long. Vim only deals with lines of up to about 510 bytes. To see whether lines are ignored set **'verbose'** to 5 or higher. Non-Emacs tags file lines can be any length.

#### tags-option

The **'tags'** option is a list of file names. Each of these files is searched for the tag. This can be used to use a different tags file than the default file "tags". It can also be used to access a common tags file.

The next file in the list is not used when:

- A matching static tag for the current buffer has been found.
- A matching global tag has been found.

This also depends on whether case is ignored. Case is ignored when:

- **'tagcase'** is "followic" and **'ignorecase'** is set
- **'tagcase'** is "ignore"
- **'tagcase'** is "smart" and the pattern only contains lower case characters.
- **'tagcase'** is "followscs" and **'smartcase'** is set and the pattern only contains lower case characters.

If case is not ignored, and the tags file only has a match without matching case, the next tags file is searched for a match with matching case. If no

tag with matching case is found, the first match without matching case is used. If case is ignored, and a matching global tag with or without matching case is found, this one is used, no further tags files are searched.

When a tag file name starts with "./", the '.' is replaced with the path of the current file. This makes it possible to use a tags file in the directory where the current file is (no matter what the current directory is). The idea of using "." is that you can define which tag file is searched first: In the current directory ("tags,./tags") or in the directory of the current file ("./tags,tags").

For example:

```
:set tags=./tags,tags,/home/user/commontags
```

In this example the tag will first be searched for in the file "tags" in the directory where the current file is. Next the "tags" file in the current directory. If it is not found there, then the file "/home/user/commontags" will be searched for the tag.

This can be switched off by including the 'd' flag in '**cptions**', to make it Vi compatible. "./tags" will then be the tags file in the current directory, instead of the tags file in the directory where the current file is.

Instead of the comma a space may be used. Then a backslash is required for the space to be included in the string option:

```
:set tags=tags\ /home/user/commontags
```

To include a space in a file name use three backslashes. To include a comma in a file name use two backslashes. For example, use:

```
:set tags=tag\\\ file,/home/user/common\\,tags
```

for the files "tag file" and "/home/user/common,tags". The '**tags**' option will have the value "tag\ file,/home/user/common,tags".

If the '**tagrelative**' option is on (which is the default) and using a tag file in another directory, file names in that tag file are relative to the directory where the tag file is.

---

## 5. Tags file format

tags-file-format E431

ctags jtags

A tags file can be created with an external command, for example "ctags". It will contain a tag for each function. Some versions of "ctags" will also make a tag for each "#defined" macro, typedefs, enums, etc.

Some programs that generate tags files:

ctags As found on most Unix systems. Only supports C. Only does the basic work.

universal ctags A maintained version of ctags based on exuberant ctags. See <https://ctags.io>.

exuberant ctags This is a very good one. It works for C, C++, Java, [Exuberant\\_ctags](#)

	Fortran, Eiffel and others. It can generate tags for many items. See <a href="http://ctags.sourceforge.net">http://ctags.sourceforge.net</a> . No new version since 2009.
etags	Connected to Emacs. Supports many languages.
JTags	For Java, in Java. It can be found at <a href="http://www.fleiner.com/jtags/">http://www.fleiner.com/jtags/</a> .
ptags.py	For Python, in Python. Found in your Python source directory at Tools/scripts/ptags.py.
ptags	For Perl, in Perl. It can be found at (link seems dead): <a href="http://www.eleves.ens.fr:8080/home/nthiery/Tags/">http://www.eleves.ens.fr:8080/home/nthiery/Tags/</a> .
gnatxref	For Ada. See <a href="http://www.gnuada.org/">http://www.gnuada.org/</a> . gnatxref is part of the gnat package.

The lines in the tags file must have one of these two formats:

1. {tagname}                    {TAB} {tagfile} {TAB} {tagaddress}
2. {tagname}                    {TAB} {tagfile} {TAB} {tagaddress} {term} {field} ..

Previously an old format was supported, see [tag-old-static](#) .

The first format is a normal tag, which is completely compatible with Vi. It is the only format produced by traditional ctags implementations. This is often used for functions that are global, also referenced in other files.

The lines in the tags file can end in <NL> or <CR><NL>. On the Macintosh <CR> also works. The <CR> and <NL> characters can never appear inside a line.

The second format is new. It includes additional information in optional fields at the end of each line. It is backwards compatible with Vi. It is only supported by new versions of ctags (such as Universal ctags or Exuberant ctags).

{tagname}	The identifier. Normally the name of a function, but it can be any identifier. It cannot contain a <Tab>.
{TAB}	One <Tab> character. <b>Note:</b> previous versions allowed any white space here. This has been abandoned to allow spaces in {tagfile}.
{tagfile}	The file that contains the definition of {tagname}. It can have an absolute or relative path. It may contain environment variables and wildcards (although the use of wildcards is doubtful). It cannot contain a <Tab>.
{tagaddress}	The Ex command that positions the cursor on the tag. It can be any Ex command, although restrictions apply (see <a href="#">tag-security</a> ). Posix only allows line numbers and search commands, which are mostly used.
{term}	;" The two characters semicolon and double quote. This is interpreted by Vi as the start of a comment, which makes the following be ignored. This is for backwards compatibility with Vi, it ignores the following fields. Example: <pre>APP     file     /^static int APP;\$/;"     v</pre> When {tagaddress} is not a line number or search pattern, then {term} must be  ;" . Here the bar ends the command (excluding

the bar) and ";" is used to have Vi ignore the rest of the line. Example:

```
APP file.c call cursor(3, 4)|;" v
```

{field} .. A list of optional fields. Each field has the form:

```
<Tab>{fieldname}:{value}
```

The {fieldname} identifies the field, and can only contain alphabetical characters [a-zA-Z].

The {value} is any string, but cannot contain a <Tab>.

These characters are special:

```
"\t" stands for a <Tab>
```

```
"\r" stands for a <CR>
```

```
"\n" stands for a <NL>
```

```
"\" stands for a single \" character
```

There is one field that doesn't have a ':'. This is the kind of the tag. It is handled like it was preceded with "kind:". In the above example, this was "kind:v" (typically variable). See the documentation of ctags for the kinds it produces, with ctags you can use `ctags --list-kinds` .

The only other field currently recognized by Vim is "file:" (with an empty value). It is used for a static tag.

The first lines in the tags file can contain lines that start with

```
!_TAG_
```

These are sorted to the first lines, only rare tags that start with "!" can sort to before them. Vim recognizes two items. The first one is the line that indicates if the file was sorted. When this line is found, Vim uses binary searching for the tags file:

```
!_TAG_FILE_SORTED<Tab>1<Tab>{anything}
```

A tag file may be case-fold sorted to avoid a linear search when case is ignored. (Case is ignored when 'ignorecase' is set and 'tagcase' is "followic", or when 'tagcase' is "ignore".) See 'tagbsearch' for details. The value '2' should be used then:

```
!_TAG_FILE_SORTED<Tab>2<Tab>{anything}
```

The other tag that Vim recognizes is the encoding of the tags file:

```
!_TAG_FILE_ENCODING<Tab>utf-8<Tab>{anything}
```

Here "utf-8" is the encoding used for the tags. Vim will then convert the tag being searched for from 'encoding' to the encoding of the tags file. And when listing tags the reverse happens. When the conversion fails the unconverted tag is used.

tag-search

The command can be any Ex command, but often it is a search command.

Examples:

```
tag1 file1 /^main(argc, argv)/
tag2 file2 108
```

The command is always executed with **'magic'** not set. The only special characters in a search pattern are `"^"` (begin-of-line) and `"$"` (<EOL>). See [pattern](#) . **Note** that you must put a backslash before each backslash in the search text. This is for backwards compatibility with Vi.

E434 E435

If the command is a normal search command (it starts and ends with `"/"` or `"?"`), some special handling is done:

- Searching starts on line 1 of the file.

The direction of the search is forward for `"/"`, backward for `"?"`.

**Note** that **'wrapscan'** does not matter, the whole file is always searched.

- If the search fails, another try is done ignoring case. If that fails too, a search is done for:

```
"^tagname[\t]*("
```

(the tag with `'^'` prepended and `"[ \t]*("` appended). When using function names, this will find the function name when it is in column 0. This will help when the arguments to the function have changed since the tags file was made. If this search also fails another search is done with:

```
"^[#a-zA-Z_].*\<tagname[\t]*("
```

This means: A line starting with `'#'` or an identifier and containing the tag followed by white space and a `'('`. This will find macro names and function names with a type prepended.

tag-old-static

Until March 2019 (patch 8.1.1092) an outdated format was supported:

```
{tagfile}:{tagname} {TAB} {tagfile} {TAB} {tagaddress}
```

This format is for a static tag only. It is obsolete now, replaced by the second format. It is only supported by Elvis 1.x, older Vim versions and a few versions of ctags. A static tag is often used for functions that are local, only referenced in the file `{tagfile}`. **Note** that for the static tag, the two occurrences of `{tagfile}` must be exactly the same. Also see [tags-option](#) below, for how static tags are used.

The support was removed, since when you can update to the new [Vim version you](#) should also be able to update ctags to one that supports the second format.

=====  
6. Include file searches

include-search    definition-search  
E387    E388    E389

These commands look for a string in the current file and in all encountered included files (recursively). This can be used to find the definition of a variable, function or macro. If you only want to search in the current buffer, use the commands listed at [pattern-searches](#) .

These commands are not available when the `+find_in_path` feature was disabled at compile time.

When a line is encountered that includes another file, that file is searched before continuing in the current buffer. Files included by included files are also searched. When an include file could not be found it is silently ignored. Use the `:checkpath` command to discover which files could not be

found, possibly your **'path'** option is not set up correctly. **Note:** the included file is searched, not a buffer that may be editing that file. Only for the current file the lines in the buffer are used.

The string can be any keyword or a defined macro. For the keyword any match will be found. For defined macros only lines that match with the **'define'** option will be found. The default is `^\#\s*define`, which is for C programs. For other languages you probably want to change this. See **'define'** for an example for C++. The string cannot contain an end-of-line, only matches within a line are found.

When a match is found for a defined macro, the displaying of lines continues with the next line when a line ends in a backslash.

The commands that start with `"["` start searching from the start of the current file. The commands that start with `"]"` start at the current cursor position.

The **'include'** option is used to define a line that includes another file. The default is `^\#\s*include`, which is for C programs. **Note:** Vim does not recognize C syntax, if the **'include'** option matches a line inside `"#ifdef/#endif"` or inside a comment, it is searched anyway. The **'isfname'** option is used to recognize the file name that comes after the matched pattern.

The **'path'** option is used to find the directory for the include files that do not have an absolute path.

The **'comments'** option is used for the commands that display a single line or jump to a line. It defines patterns that may start a comment. Those lines are ignored for the search, unless `[!]` is used. One exception: When the line matches the pattern `^\# *define` it is not considered to be a comment.

If you want to list matches, and then select one to jump to, you could use a mapping to do that for you. Here is an example:

```
:map <F4> [I:let nr = input("Which one: ")<Bar>exe "normal " .. nr .. "[\t"<CR>
```

```
[i [i
Display the first line that contains the keyword
under the cursor. The search starts at the beginning
of the file. Lines that look like a comment are
ignored (see 'comments' option). If a count is given,
the count'th matching line is displayed, and comment
lines are not ignored.
```

```
]i]i
like "[i", but start at the current cursor position.
```

```
:[range]is[earch][!] [count] [/]pattern[/] :is :isearch
Like "[i" and "]i", but search in [range] lines
(default: whole file).
See :search-args for [/] and [!].
```

[I [I  
 Display all lines that contain the keyword under the cursor. Filenames and line numbers are displayed for the found lines. The search starts at the beginning of the file.

]I ]I  
 like "[I", but start at the current cursor position.

:il :ilist  
 :[range]il[ist][!] [/]pattern[/  
 Like "[I" and "]I", but search in [range] lines (default: whole file).  
 See :search-args for [/] and [!].

[ **CTRL-I** [\_CTRL-I  
 Jump to the first line that contains the keyword under the cursor. The search starts at the beginning of the file. Lines that look like a comment are ignored (see 'comments' option). If a count is given, the count'th matching line is jumped to, and comment lines are not ignored.

] **CTRL-I** ]\_CTRL-I  
 like "[ **CTRL-I**", but start at the current cursor position.

:ij :ijump  
 :[range]ij[ump][!] [count] [/]pattern[/  
 Like "[ **CTRL-I**" and "] **CTRL-I**", but search in [range] lines (default: whole file).  
 See :search-args for [/] and [!].

**CTRL-W CTRL-I** CTRL-W\_CTRL-I CTRL-W\_i  
**CTRL-W i**  
 Open a new window, with the cursor on the first line that contains the keyword under the cursor. The search starts at the beginning of the file. Lines that look like a comment line are ignored (see 'comments' option). If a count is given, the count'th matching line is jumped to, and comment lines are not ignored.

:isp :isplit  
 :[range]isp[lit][!] [count] [/]pattern[/  
 Like "**CTRL-W i**" and "**CTRL-W i**", but search in [range] lines (default: whole file).  
 See :search-args for [/] and [!].

[d [d  
 Display the first macro definition that contains the macro under the cursor. The search starts from the beginning of the file. If a count is given, the count'th matching line is displayed.

`]d` like "[d", but start at the current cursor position.

`:ds` `:dsearch`

`:[range]ds[earch][!] [count] [/]string[/]`  
 Like "[d" and "]d", but search in [range] lines (default: whole file).  
 See `:search-args` for [/] and [!].

`[D` Display all macro definitions that contain the macro under the cursor. Filenames and line numbers are displayed for the found lines. The search starts from the beginning of the file.

`]D` like "[D", but start at the current cursor position.

`:dli` `:dlist`

`:[range]dli[st][!] [/]string[/]`  
 Like `[D` and `]D`, but search in [range] lines (default: whole file).  
 See `:search-args` for [/] and [!].  
 Note that `:dl` works like :delete` with the "l" flag, not :dlist`.`

`[ CTRL-D` Jump to the first macro definition that contains the keyword under the cursor. The search starts from the beginning of the file. If a count is given, the count'th matching line is jumped to.

`] CTRL-D` like "[ CTRL-D", but start at the current cursor position.

`:dj` `:djump`

`:[range]dj[ump][!] [count] [/]string[/]`  
 Like "[ CTRL-D" and "] CTRL-D", but search in [range] lines (default: whole file).  
 See `:search-args` for [/] and [!].

`CTRL-W CTRL-D` `CTRL-W_CTRL-D` `CTRL-W_d`  
`CTRL-W d` Open a new window, with the cursor on the first macro definition line that contains the keyword under the cursor. The search starts from the beginning of the file. If a count is given, the count'th matching line is jumped to.

`:dsp` `:dsplit`

`:[range]dsp[lit][!] [count] [/]string[/]`  
 Like "CTRL-W d", but search in [range] lines (default: whole file).  
 See `:search-args` for [/] and [!].

```

:che[ckpath] :che :chec :check :checkpath
 List all the included files that could not be found.

:che[ckpath]! List all the included files.

```

:search-args

Common arguments for the commands above:

```
[!] When included, find matches in lines that are recognized as comments.
 When excluded, a match is ignored when the line is recognized as a
 comment (according to 'comments'), or the match is in a C comment
 (after "//" or inside /* */). Note that a match may be missed if a
 line is recognized as a comment, but the comment ends halfway the line.
 And if the line is a comment, but it is not recognized (according to
 'comments') a match may be found in it anyway. Example:
```

```

/* comment
 foobar */

```

A match for "foobar" is found, because this line is not recognized as a comment (even though syntax highlighting does recognize it).

**Note:** Since a macro definition mostly doesn't look like a comment, the [!] makes no difference for ":dlist", ":dsearch" and ":djump".

```
[/] A pattern can be surrounded by '/'. Without '/' only whole words are
 matched, using the pattern "<pattern>". Only after the second '/' a
 next command can be appended with '|'. Example:
```

```
:isearch /string/ | echo "the last one"
```

For a ":djump", ":dsplit", ":dlist" and ":dsearch" command the pattern is used as a literal string, not as a search pattern.

---

## 7. Using 'tagfunc'

tag-function

It is possible to provide Vim with a function which will generate a list of tags used for commands like `:tag`, `:tselect` and Normal mode tag commands like `CTRL-]`.

The function used for generating the taglist is specified by setting the **'tagfunc'** option. The function will be called with three arguments:

pattern	The tag identifier or pattern used during the tag search.
flags	String containing flags to control the function behavior.
info	Dict containing the following entries:
buf_ffname	Full filename which can be used for priority.
user_data	Custom data String, if stored in the tag stack previously by tagfunc.

**Note** that in a legacy function "a:" needs to be prepended to the argument name when using it.

Currently up to three flags may be passed to the tag function:

'c'	The function was invoked by a normal command being processed (mnemonic: the tag function may use the context around the cursor to perform a better job of generating the tag list.)
'i'	In Insert mode, the user was completing a tag (with <code>i_CTRL-X_CTRL-]</code> or <b>'completeopt'</b> contains <code>t`</code> ).
'r'	The first argument to tagfunc should be interpreted as a

`pattern` (see `tag-regexp` ), such as when using:  
`:tag /pat`

It is also given when completing in insert mode.

If this flag is not present, the argument is usually taken literally as the full tag name.

**Note** that when `'tagfunc'` is set, the priority of the tags described in `tag-priority` does not apply. Instead, the priority is exactly as the ordering of the elements in the list returned by the function.

E987

The function should return a List of Dict entries. Each Dict must at least include the following entries and each value must be a string:

<code>name</code>	Name of the tag.
<code>filename</code>	Name of the file where the tag is defined. It is either relative to the current directory or a full path.
<code>cmd</code>	Ex command used to locate the tag in the file. This can be either an Ex search pattern or a line number.

**Note** that the format is similar to that of `taglist()` , which makes it possible to use its output to generate the result.

The following fields are optional:

<code>kind</code>	Type of the tag.
<code>user_data</code>	String of custom data stored in the tag stack which can be used to disambiguate tags between operations.

If the function returns `v:null` instead of a List, a standard tag lookup will be performed instead.

It is not allowed to change the tagstack from inside `'tagfunc'`. E986

It is not allowed to close a window or change window from inside `'tagfunc'`.

E1299

The following is a hypothetical example of a function used for `'tagfunc'`. It uses the output of `taglist()` to generate the result: a list of tags in the inverse order of file names.

```
function TagFunc(pattern, flags, info)
 function CompareFileNames(item1, item2)
 let f1 = a:item1['filename']
 let f2 = a:item2['filename']
 return f1 >=# f2 ?
 \ -1 : f1 <=# f2 ? 1 : 0
 endfunction

 let result = taglist(a:pattern)
 call sort(result, "CompareFileNames")

 return result
endfunc
set tagfunc=TagFunc
```

Editing with multiple windows and buffers. [windows](#) [buffers](#)

The commands which have been added to use multiple windows and buffers are explained here. Additionally, there are explanations for commands that work differently when used in combination with more than one window.

The basics are explained in chapter 7 and 8 of the user manual [usr\\_07.txt](#) [usr\\_08.txt](#) .

{not able to use multiple windows when the [+windows](#) feature was disabled at compile time}

- 
1. Introduction [windows-intro](#) [window](#)

Summary:

- A buffer is the in-memory text of a file.
- A window is a viewport on a buffer.
- A tab page is a collection of windows.

A window is a viewport onto a buffer. You can use multiple windows on one buffer, or several windows on different buffers.

A buffer is a file loaded into memory for editing. The original file remains unchanged until you write the buffer to the file.

A buffer can be in one of three states:

[active-buffer](#)  
active: The buffer is displayed in a window. If there is a file for this buffer, it has been read into the buffer. The buffer may have been modified since then and thus be different from the file.

[hidden-buffer](#)  
hidden: The buffer is not displayed. If there is a file for this buffer, it has been read into the buffer. Otherwise it's the same as an active

buffer, you just can't see it.

### inactive-buffer

inactive: The buffer is not displayed and does not contain anything. Options for the buffer are remembered if the file was once loaded. It can contain marks from the `viminfo` file. But the buffer doesn't contain text.

In a table:

state	displayed in window	loaded	":buffers" shows
active	yes	yes	'a'
hidden	no	yes	'h'
inactive	no	no	' '

### buffer-reuse

Each buffer has a unique number and the number will not change within a Vim session. The `bufnr()` and `bufname()` functions can be used to convert between a buffer name and the buffer number. There is one exception: if a new empty buffer is created and it is not modified, the buffer will be re-used when loading another file into that buffer. This also means the buffer number will not change.

The main Vim window can hold several split windows. There are also tab pages `tab-page`, each of which can hold multiple windows.

### window-ID winid windowid

Each window has a unique identifier called the window ID. This identifier will not change within a Vim session. The `win_getid()` and `win_id2tabwin()` functions can be used to convert between the window/tab number and the identifier. There is also the window number, which may change whenever windows are opened or closed, see `winnr()`. The window number is only valid in one specific tab. The window ID is valid across tabs. For most functions that take a window ID or a window number, the window number only applies to the current tab, while the window ID can refer to a window in any tab.

---

## 2. Starting Vim

### windows-starting

By default, Vim starts with one window, just like Vi.

The `"-o"` and `"-O"` arguments to Vim can be used to open a window for each file in the argument list. The `"-o"` argument will split the windows horizontally; the `"-O"` argument will split the windows vertically. If both `"-o"` and `"-O"` are given, the last one encountered will be used to determine the split orientation. For example, this will open three windows, split horizontally:

```
vim -o file1 file2 file3
```

`"-oN"`, where N is a decimal number, opens N windows split horizontally. If there are more file names than windows, only N windows are opened and some files do not get a window. If there are more windows than file names, the last few windows will be editing empty buffers. Similarly, `"-ON"` opens N

windows split vertically, with the same restrictions.

If there are many file names, the windows will become very small. You might want to set the **'winheight'** and/or **'winwidth'** options to create a workable situation.

Buf/Win Enter/Leave **autocommand**s are not executed when opening the new windows and reading the files, that's only done when they are really entered.

A status line will be used to separate windows. The **'laststatus'** option tells when the last window also has a status line:

```

'laststatus' = 0 never a status line
'laststatus' = 1 status line if there is more than one window
'laststatus' = 2 always a status line
```

You can change the contents of the status line with the **'statusline'** option. This option can be local to the window, so that you can have a different status line in each window.

Normally, inversion is used to display the status line. This can be changed with the 's' character in the **'highlight'** option. For example, "sb" sets it to bold characters. If no highlighting is used for the status line ("sn"), the '^' character is used for the current window, and '=' for other windows. If the mouse is supported and enabled with the **'mouse'** option, a status line can be dragged to resize windows.

**Note:** If you expect your status line to be in reverse video and it isn't, check if the **'highlight'** option contains "si". In version 3.0, this meant to invert the status line. Now it should be "sr", reverse the status line, as "si" now stands for italic! If italic is not available on your terminal, the status line is inverted anyway; you will only see this problem on terminals that have termcap codes for italics.

The lines after the last buffer line in a window are called filler lines. By default, these lines start with a tilde (~) character. The **'eob'** item in the **'fillchars'** option can be used to change this character. By default, these characters are highlighted as NonText ( **hl-NonText** ). The EndOfBuffer highlight group ( **hl-EndOfBuffer** ) can be used to change the highlighting of the filler characters.

---

### 3. Opening and closing a window opening-window

```

CTRL-W s CTRL-W_s
CTRL-W S CTRL-W_S
CTRL-W CTRL-S CTRL-W_CTRL-S
:[N]sp[lit] [+opt] [+cmd] [file] :sp :split
Split current window in two. The result is two viewports on
the same file.
```

Make the new window N high (default is to use half the height of the current window). Reduces the current window height to

create room (and others, if the **'equalalways'** option is set, **'eadirection'** isn't "hor", and one of them is higher than the current or the new window).

If [file] is given it will be edited in the new window. If it is not loaded in any buffer, it will be read. Else the new window will use the already loaded buffer.

**Note:** CTRL-S does not work on all terminals and might block further input, use **CTRL-Q** to get going again. Also see ++opt and +cmd .

E242 E1159

Be careful when splitting a window in an autocommand, it may mess up the window layout if this happens while making other window layout changes.

**CTRL-W CTRL-V**

CTRL-W\_CTRL-V

**CTRL-W v**

CTRL-W\_v

:[N]vs[plit] [++opt] [+cmd] [file]

:vs :vsplit

Like :split , but split vertically. The windows will be spread out horizontally if

1. a width was not specified,
2. **'equalalways'** is set,
3. **'eadirection'** isn't "ver", and
4. one of the other windows is wider than the current or new window.

If N was given make the new window N columns wide, if possible.

**Note:** In other places **CTRL-Q** does the same as **CTRL-V**, but here it doesn't!

**CTRL-W n**

CTRL-W\_n

**CTRL-W CTRL-N**

CTRL-W\_CTRL-N

:[N]new [++opt] [+cmd]

:new

Create a new window and start editing an empty file in it. Make new window N high (default is to use half the existing height). Reduces the current window height to create room (and others, if the **'equalalways'** option is set and **'eadirection'** isn't "hor").

Also see ++opt and +cmd .

If **'fileformats'** is not empty, the first format given will be used for the new buffer. If **'fileformats'** is empty, the **'fileformat'** of the current buffer is used. This can be overridden with the ++opt argument.

Autocommands are executed in this order:

1. WinLeave for the current window
2. WinEnter for the new window
3. BufLeave for the current buffer
4. BufEnter for the new buffer

This behaves like a ":split" first, and then an ":enew" command.

:[N]new [++opt] [+cmd] {file}

:[N]sp[plit] [++opt] [+cmd] {file}

:split\_f

Create a new window and start editing file `{file}` in it. This behaves almost like a `":split"` first, and then an `":edit"` command, but the alternate file name in the original window is set to `{file}`.

If `[+cmd]` is given, execute the command when the file has been loaded `+cmd` .

Also see `++opt` .

Make new window N high (default is to use half the existing height). Reduces the current window height to create room (and others, if the `'equalalways'` option is set).

`:[N]vne[w] [++opt] [+cmd] [file]` :vne :vnew  
Like `:new` , but split vertically. If `'equalalways'` is set and `'eadirection'` isn't "ver" the windows will be spread out horizontally, unless a width was specified.

`:[N]sv[iew] [++opt] [+cmd] [file]` :sv :sview splitview  
Same as `":split"`, but set `'readonly'` option for this buffer.

`:[N]sf[ind] [++opt] [+cmd] {file}` :sf :sfi :sfind splitfind  
Same as `":split"`, but search for `{file}` in `'path'` like in `:find` . Doesn't split if `{file}` is not found.

**CTRL-W CTRL-^** CTRL-W\_CTRL-^ CTRL-W\_^  
**CTRL-W ^** Split the current window in two and edit the alternate file. When a count N is given, split the current window and edit buffer N. Similar to `":sp #"` and `":sp #N"`, but it allows the other buffer to be unnamed. This command matches the behavior of `CTRL-^` , except that it splits a window first.

**CTRL-W :** CTRL-W\_:  
Does the same as typing `:` - enter a command line. Useful in a terminal window, where all Vim commands must be preceded with **CTRL-W** or `'termwinkey'`.

Note that the `'splitbelow'` and `'splitright'` options influence where a new window will appear.

E36

Creating a window will fail if there is not enough room. Every window needs at least one screen line and column, sometimes more. Options `'winminheight'` and `'winminwidth'` are relevant.

`:vert[ical] {cmd}` :vert :vertical  
Execute `{cmd}`. If it contains a command that splits a window, it will be split vertically. For ``vertical wincmd =`` windows will be equalized only vertically. Doesn't work for `:execute` and `:normal` .

`:hor[izontal] {cmd}` :hor :horizontal  
Execute `{cmd}`. Currently only makes a difference for ``horizontal wincmd =``, which will equalize windows only horizontally.

`:lefta[bove] {cmd}` `:lefta` `:leftabove`  
`:abo[veleft] {cmd}` `:abo` `:aboveleft`  
 Execute {cmd}. If it contains a command that splits a window, it will be opened left (vertical split) or above (horizontal split) the current window. Overrides **'splitbelow'** and **'splitright'**.  
 Doesn't work for `:execute` and `:normal` .

`:rightb[elow] {cmd}` `:rightb` `:rightbelow`  
`:bel[owright] {cmd}` `:bel` `:belowright`  
 Execute {cmd}. If it contains a command that splits a window, it will be opened right (vertical split) or below (horizontal split) the current window. Overrides **'splitbelow'** and **'splitright'**.  
 Doesn't work for `:execute` and `:normal` .

`:topleft` E442

`:to[pleft] {cmd}`  
 Execute {cmd}. If it contains a command that splits a window, it will appear at the top and occupy the full width of the Vim window. When the split is vertical the window appears at the far left and occupies the full height of the Vim window.  
 Doesn't work for `:execute` and `:normal` .

`:bo` `:botright`

`:bo[tright] {cmd}`  
 Execute {cmd}. If it contains a command that splits a window, it will appear at the bottom and occupy the full width of the Vim window. When the split is vertical the window appears at the far right and occupies the full height of the Vim window.  
 Doesn't work for `:execute` and `:normal` .

These command modifiers can be combined to make a vertically split window occupy the full height. Example:

`:vertical topleft split tags`

Opens a vertically split, full-height window on the "tags" file at the far left of the Vim window.

### Closing a window

---

`:q[uit]`  
`:{count}q[uit]` `:count_quit`  
**CTRL-W q** `CTRL-W_q`  
**CTRL-W CTRL-Q** `CTRL-W_CTRL-Q`  
 Without {count}: Quit the current window. If {count} is given quit the {count} window.

`edit-window`

When quitting the last edit window (not counting help or preview windows), exit Vim.

When **'hidden'** is set, and there is only one window for the

current buffer, it becomes hidden. When **'hidden'** is not set, and there is only one window for the current buffer, and the buffer was changed, the command fails.

(Note: **CTRL-Q** does not work on all terminals).

If `[count]` is greater than the last window number the last window will be closed:

```
:1quit " quit the first window
:$quit " quit the last window
:9quit " quit the last window
 " if there are fewer than 9 windows opened
:-quit " quit the previous window
:+quit " quit the next window
:+2quit " quit the second next window
```

When closing a help window, and this is not the only window, Vim will try to restore the previous window layout, see `:helpclose`.

```
:q[uit]!
:{count}q[uit]!
```

Without `{count}`: Quit the current window. If `{count}` is given quit the `{count}` window.

If this was the last window for a buffer, any changes to that buffer are lost. When quitting the last window (not counting help windows), exit Vim. The contents of the buffer are lost, even when **'hidden'** is set.

```
:clo[se][!]
:{count}clo[se][!]
```

**CTRL-W c** CTRL-W\_c :clo :close

Without `{count}`: Close the current window. If `{count}` is given close the `{count}` window.

When the **'hidden'** option is set, or when the buffer was changed and the `[!]` is used, the buffer becomes hidden (unless there is another window editing it).

When there is only one `edit-window` in the current tab page and there is another tab page, this closes the current tab page. `tab-page`.

This command fails when: E444

- There is only one window on the screen.
- When **'hidden'** is not set, `[!]` is not used, the buffer has changes, and there is no other window on this buffer.

Changes to the buffer are not written and won't get lost, so this is a "safe" command.

**CTRL-W CTRL-C** CTRL-W\_CTRL-C

You might have expected that **CTRL-W CTRL-C** closes the current window, but that does not work, because the **CTRL-C** cancels the

command.

`:hide`

`:hid[e]`  
`:{count}hid[e]`

Without `{count}`: Quit the current window, unless it is the last window on the screen.  
If `{count}` is given quit the `{count}` window.

The buffer becomes hidden (unless there is another window editing it or `'bufhidden'` is "unload", "delete" or "wipe").  
If the window is the last one in the current tab page the tab page is closed. `tab-page`

The value of `'hidden'` is irrelevant for this command. Changes to the buffer are not written and won't get lost, so this is a "safe" command.

`:hid[e] {cmd}` Execute `{cmd}` with `'hidden'` set. The previous value of `'hidden'` is restored after `{cmd}` has been executed.

Example:

`:hide edit Makefile`

This will edit "Makefile", and hide the current buffer if it has any changes.

`:on[ly][!]`  
`:{count}on[ly][!]`

**CTRL-W o**  
**CTRL-W CTRL-O**

`CTRL-W_o` E445  
`CTRL-W_CTRL-O` `:on` `:only`

Make the current window the only one on the screen. All other windows are closed. For `{count}` see the `:quit` command above `:count_quit`.

When the `'hidden'` option is set, all buffers in closed windows become hidden.

When `'hidden'` is not set, and the `'autowrite'` option is set, modified buffers are written. Otherwise, windows that have buffers that are modified are not removed, unless the `[!]` is given, then they become hidden. But modified buffers are never abandoned, so changes cannot get lost.

---

#### 4. Moving cursor to other windows

`window-move-cursor`

**CTRL-W <Down>**  
**CTRL-W CTRL-J**  
**CTRL-W j**

`CTRL-W_<Down>`  
`CTRL-W_CTRL-J` `CTRL-W_j`

Move cursor to Nth window below current one. Uses the cursor position to select between alternatives.

**CTRL-W <Up>**  
**CTRL-W CTRL-K**  
**CTRL-W k**

`CTRL-W_<Up>`  
`CTRL-W_CTRL-K` `CTRL-W_k`

Move cursor to Nth window above current one. Uses the cursor position to select between alternatives.

<b>CTRL-W</b> <Left>		CTRL-W_<Left>
<b>CTRL-W CTRL-H</b>		CTRL-W_CTRL-H
<b>CTRL-W</b> <BS>		CTRL-W_<BS> CTRL-W_h
<b>CTRL-W</b> h	Move cursor to Nth window left of current one. Uses the cursor position to select between alternatives.	
<b>CTRL-W</b> <Right>		CTRL-W_<Right>
<b>CTRL-W CTRL-L</b>		CTRL-W_CTRL-L CTRL-W_l
<b>CTRL-W</b> l	Move cursor to Nth window right of current one. Uses the cursor position to select between alternatives.	
<b>CTRL-W</b> w		CTRL-W_w CTRL-W_CTRL-W
<b>CTRL-W CTRL-W</b>	Without count: move cursor to window below/right of the current one. If there is no window below or right, go to top-left window. With count: go to Nth window (windows are numbered from top-left to bottom-right). To obtain the window number see <code>bufwinnr()</code> and <code>winnr()</code> . When N is larger than the number of windows go to the last window.	
		CTRL-W_W
<b>CTRL-W</b> W	Without count: move cursor to window above/left of current one. If there is no window above or left, go to bottom-right window. With count: go to Nth window, like with <b>CTRL-W</b> w.	
<b>CTRL-W</b> t		CTRL-W_t CTRL-W_CTRL-T
<b>CTRL-W CTRL-T</b>	Move cursor to top-left window.	
<b>CTRL-W</b> b		CTRL-W_b CTRL-W_CTRL-B
<b>CTRL-W CTRL-B</b>	Move cursor to bottom-right window.	
<b>CTRL-W</b> p		CTRL-W_p CTRL-W_CTRL-P
<b>CTRL-W CTRL-P</b>	Go to previous (last accessed) window.	
		CTRL-W_P E441
<b>CTRL-W</b> P	Go to preview window. When there is no preview window this is an error. {not available when compiled without the  +quickfix  feature}	

If Visual mode is active and the new window is not for the same buffer, the Visual mode is ended. If the window is on the same buffer, the cursor position is set to keep the same Visual area selected.

:winc :wincmd

These commands can also be executed with ":wincmd":

`:[count]winc[md] {arg}`

Like executing **CTRL-W** [count] {arg}. Example:

:wincmd j

Moves to the window below the current one.

This command is useful when a Normal mode cannot be used (for the `CursorHold` autocommand event). Or when a Normal mode command is inconvenient.

The count can also be a window number. Example:  
:exe nr .. "wincmd w"  
This goes to window "nr".

**Note:** All **CTRL-W** commands can also be executed with `:wincmd`, for those places where a Normal mode command can't be used or is inconvenient (e.g. in a browser-based terminal).

---

## 5. Moving windows around

### window-moving

**CTRL-W r** CTRL-W\_r CTRL-W\_CTRL-R E443  
**CTRL-W CTRL-R** Rotate windows downwards/rightwards. The first window becomes the second one, the second one becomes the third one, etc. The last window becomes the first window. The cursor remains in the same window.  
This only works within the row or column of windows that the current window is in.

**CTRL-W R** CTRL-W\_R  
Rotate windows upwards/leftwards. The second window becomes the first one, the third one becomes the second one, etc. The first window becomes the last window. The cursor remains in the same window.  
This only works within the row or column of windows that the current window is in.

**CTRL-W x** CTRL-W\_x CTRL-W\_CTRL-X  
**CTRL-W CTRL-X** Without count: Exchange current window with next one. If there is no next window, exchange with previous window.  
With count: Exchange current window with Nth window (first window is 1). The cursor is put in the other window.  
When vertical and horizontal window splits are mixed, the exchange is only done in the row or column of windows that the current window is in.

The following commands can be used to change the window layout. For example, when there are two vertically split windows, **CTRL-W K** will change that in horizontally split windows. **CTRL-W H** does it the other way around.

**CTRL-W K** CTRL-W\_K  
Move the current window to be at the very top, using the full width of the screen. This works like `:topleft split`, except it is applied to the current window and no new window is created.

**CTRL-W J** CTRL-W\_J  
Move the current window to be at the very bottom, using the full width of the screen. This works like `:botright split`, except it is applied to the current window and no new window is created.

**CTRL-W H** CTRL-W\_H  
Move the current window to be at the far left, using the

full height of the screen. This works like `:vert topleft split`, except it is applied to the current window and no new window is created.

**CTRL-W L** CTRL-W\_L  
Move the current window to be at the far right, using the full height of the screen. This works like `:vert botright split`, except it is applied to the current window and no new window is created.

**CTRL-W T** CTRL-W\_T  
Move the current window to a new tab page. This fails if there is only one window in the current tab page. This works like `:tab split`, except the previous window is closed.  
When a count is specified the new tab page will be opened before the tab page with this index. Otherwise it comes after the current tab page.

---

## 6. Window resizing

window-resize

**CTRL-W =** CTRL-W\_=  
Make all windows (almost) equally high and wide, but use `'winheight'` and `'winwidth'` for the current window. Windows with `'winfixheight'` set keep their height and windows with `'winfixwidth'` set keep their width.  
To equalize only vertically (make window equally high) use `'vertical wincmd ='`.  
To equalize only horizontally (make window equally wide) use `'horizontal wincmd ='`.

`:res[ize] -N` :res :resize CTRL-W\_-  
**CTRL-W -** Decrease current window height by N (default 1).  
If used after `:vertical` : decrease width by N.

`:res[ize] +N` CTRL-W\_+  
**CTRL-W +** Increase current window height by N (default 1).  
If used after `:vertical` : increase width by N.

`:res[ize] [N]`  
**CTRL-W CTRL-\_** CTRL-W\_CTRL-\_ CTRL-W\_\_  
**CTRL-W \_** Set current window height to N (default: highest possible).

`:{winnr}res[ize] [+~]N`  
Like `:resize` above, but apply the size to window `{winnr}` instead of the current window.

`z{nr}<CR>` Set current window height to `{nr}`.

**CTRL-W <** CTRL-W\_<  
Decrease current window width by N (default 1).

CTRL-W\_>

**CTRL-W** > Increase current window width by N (default 1).

`:vert[ical] res[ize] [N]` :vertical-resize CTRL-W\_bar  
**CTRL-W** | Set current window width to N (default: widest possible).

You can also resize a window by dragging a status line up or down with the mouse. Or by dragging a vertical separator line left or right. This only works if the version of Vim that is being used supports the mouse and the **'mouse'** option has been set to enable it.

The option **'winheight'** ('wh') is used to set the minimal window height of the current window. This option is used each time another window becomes the current window. If the option is '0', it is disabled. Set **'winheight'** to a very large value, e.g., '9999', to make the current window always fill all available space. Set it to a reasonable value, e.g., '10', to make editing in the current window comfortable.

The equivalent **'winwidth'** ('wiw') option is used to set the minimal width of the current window.

When the option **'equalalways'** ('ea') is set, all the windows are automatically made the same size after splitting or closing a window. If you don't set this option, splitting a window will reduce the size of the current window and leave the other windows the same. When closing a window, the extra lines are given to the window above it.

The **'eadirection'** option limits the direction in which the **'equalalways'** option is applied. The default "both" resizes in both directions. When the value is "ver" only the heights of windows are equalized. Use this when you have manually resized a vertically split window and want to keep this width. Likewise, "hor" causes only the widths of windows to be equalized.

The option **'cmdheight'** ('ch') is used to set the height of the command-line. If you are annoyed by the `hit-enter` prompt for long messages, set this option to 2 or 3.

If there is only one window, resizing that window will also change the command line height. If there are several windows, resizing the current window will also change the height of the window below it (and sometimes the window above it).

The minimal height and width of a window is set with **'winminheight'** and **'winminwidth'**. These are hard values, a window will never become smaller.

### WinScrolled and WinResized autocommands

win-scrolled-resized

If you want to get notified of changes in window sizes, the `WinResized` autocommand event can be used.

If you want to get notified of text in windows scrolling vertically or horizontally, the `WinScrolled` autocommand event can be used. This will also trigger in window size changes.

Exception: the events will not be triggered when the text scrolls for **'incsearch'**.

### WinResized-event

The `WinResized` event is triggered after updating the display, several windows may have changed size then. A list of the IDs of windows that changed since last time is provided in the `v:event.windows` variable, for example:

```
[1003, 1006]
```

### WinScrolled-event

The `WinScrolled` event is triggered after `WinResized`, and also if a window was scrolled. That can be vertically (the text at the top of the window changed) or horizontally (when `'wrap'` is off or when the first displayed part of the first line changes). Note that `WinScrolled` will trigger many more times than `WinResized`, it may slow down editing a bit.

The information provided by `WinScrolled` is a dictionary for each window that has changes, using the window ID as the key, and a total count of the changes with the key "all". Example value for `v:event` (`Vim9` syntax):

```
{
 all: {width: 0, height: 2, leftcol: 0, skipcol: 0, topline: 1, topfill: 0},
 1003: {width: 0, height: -1, leftcol: 0, skipcol: 0, topline: 0, topfill: 0},
 1006: {width: 0, height: 1, leftcol: 0, skipcol: 0, topline: 1, topfill: 0},
}
```

Note that the "all" entry has the absolute values of the individual windows accumulated.

If you need more information about what changed, or you want to "debounce" the events (not handle every event to avoid doing too much work), you may want to use the `'winlayout()'` and `'getwininfo()'` functions.

`WinScrolled` and `WinResized` do not trigger when the first autocommand is added, only after the first scroll or resize. They may trigger when switching to another tab page.

The commands executed are expected to not cause window size or scroll changes. If this happens anyway, the event will trigger again very soon. In other words: Just before triggering the event, the current sizes and scroll positions are stored and used to decide whether there was a change.

### E1312

It is not allowed to change the window layout here (split, close or move windows).

=====

## 7. Argument and buffer list commands

### buffer-list

args list	buffer list	meaning
1. <code>:[N]argument [N]</code>	11. <code>:[N]buffer [N]</code>	to arg/buf N
2. <code>:[N]next [file ..]</code>	12. <code>:[N]bnext [N]</code>	to Nth next arg/buf
3. <code>:[N]Next [N]</code>	13. <code>:[N]bNext [N]</code>	to Nth previous arg/buf
4. <code>:[N]previous [N]</code>	14. <code>:[N]bprevious [N]</code>	to Nth previous arg/buf
5. <code>:rewind / :first</code>	15. <code>:brewind / :bfirst</code>	to first arg/buf
6. <code>:last</code>	16. <code>:blast</code>	to last arg/buf
7. <code>:all</code>	17. <code>:ball</code>	edit all args/buffers
	18. <code>:unhide</code>	edit all loaded buffers
	19. <code>:[N]bmod [N]</code>	to Nth modified buf

split & args list	split & buffer list	meaning
21. :[N]sargument [N]	31. :[N]sbuffer [N]	split + to arg/buf N
22. :[N]snext [file ..]	32. :[N]sbnext [N]	split + to Nth next arg/buf
23. :[N]sNext [N]	33. :[N]sbNext [N]	split + to Nth previous arg/buf
24. :[N]sprevious [N]	34. :[N]sbprevious [N]	split + to Nth previous arg/buf
25. :srewind / :sfirst	35. :sbrewind / :sbfirst	split + to first arg/buf
26. :slast	36. :sblast	split + to last arg/buf
27. :sall	37. :sball	edit all args/buffers
	38. :sunhide	edit all loaded buffers
	39. :[N]sbmod [N]	split + to Nth modified buf
40. :args	list of arguments	
41. :buffers	list of buffers	

The meaning of [N] depends on the command:

[N] is the number of buffers to go forward/backward on 2/12/22/32,  
3/13/23/33, and 4/14/24/34

[N] is an argument number, defaulting to current argument, for 1 and 21

[N] is a buffer number, defaulting to current buffer, for 11 and 31

[N] is a count for 19 and 39

**Note:** ":next" is an exception, because it must accept a list of file names for compatibility with Vi.

## The argument list and multiple windows

---

The current position in the argument list can be different for each window. Remember that when doing ":e file", the position in the argument list stays the same, but you are not editing the file at that position. To indicate this, the file message (and the title, if you have one) shows "(file (N) of M)", where "(N)" is the current position in the file list, and "M" the number of files in the file list.

All the entries in the argument list are added to the buffer list. Thus, you can also get to them with the buffer list commands, like ":bnext".

```
:[N]al[l][!] [N] :al :all :sal :sall
:[N]sal[l][!] [N]
```

Rearrange the screen to open one window for each argument. All other windows are closed. When a count is given, this is the maximum number of windows to open.

With the **:tab** modifier open a tab page for each argument. When there are more arguments than '**tabpagemax**' further ones become split windows in the last tab page.

When the '**hidden**' option is set, all buffers in closed windows become hidden.

When '**hidden**' is not set, and the '**autowrite**' option is set, modified buffers are written. Otherwise, windows that have buffers that are modified are not removed, unless the [!] is given, then they become hidden. But modified buffers are never abandoned, so changes cannot get lost.

[N] is the maximum number of windows to open. '**winheight**'

also limits the number of windows opened ('winwidth' if `:vertical` was prepended).

Buf/Win Enter/Leave autocommands are not executed for the new windows here, that's only done when they are really entered. If autocommands change the window layout while this command is busy an error will be given. E249

`:[N]sa[rgument][!] [++opt] [+cmd] [N] :sa :sargument`  
Short for `":split | argument [N]"`: split window and go to Nth argument. But when there is no such argument, the window is not split. Also see `++opt` and `+cmd`.

`:[N]sn[ext][!] [++opt] [+cmd] [file ..] :sn :snext`  
Short for `":split | [N]next"`: split window and go to Nth next argument. But when there is no next file, the window is not split. Also see `++opt` and `+cmd`.

`:[N]spr[evious][!] [++opt] [+cmd] [N] :spr :sprevious`  
`:[N]sN[ext][!] [++opt] [+cmd] [N] :sN :sNext`  
Short for `":split | [N]Next"`: split window and go to Nth previous argument. But when there is no previous file, the window is not split. Also see `++opt` and `+cmd`.

`:sre[wind][!] [++opt] [+cmd] :sre :srewind`  
Short for `":split | rewind"`: split window and go to first argument. But when there is no argument list, the window is not split. Also see `++opt` and `+cmd`.

`:sfir[st] [++opt] [+cmd] :sfir :sfirst`  
Same as `":srewind"`.

`:sla[st][!] [++opt] [+cmd] :sla :slast`  
Short for `":split | last"`: split window and go to last argument. But when there is no argument list, the window is not split. Also see `++opt` and `+cmd`.

`:dr[op] [++opt] [+cmd] {file} .. :dr :drop`  
Edit the first `{file}` in a window.  
- If the file is already open in a window change to that window.  
- If the file is not open in a window edit the file in the current window. If the current buffer can't be `abandoned`, the window is split first.  
- Windows that are not in the argument list or are not full width will be closed if possible.  
The `argument-list` is set, like with the `:next` command. The purpose of this command is that it can be used from a program that wants Vim to edit another file, e.g., a debugger. When using the `:tab` modifier each argument is opened in a tab page. The last window is used if it's empty.

Also see `++opt` and `+cmd` .

---

8. Do a command in all buffers or windows list-repeat

`:[range]windo {cmd}` :windo  
Execute `{cmd}` in each window or if `[range]` is given only in windows for which the window number lies in the `[range]`. It works like doing this:

```
CTRL-W t
:{cmd}
CTRL-W w
:{cmd}
etc.
```

This only operates in the current tab page.

When an error is detected on one window, further windows will not be visited.

The last window (or where an error occurred) becomes the current window.

`{cmd}` can contain `|` to concatenate several commands.

`{cmd}` must not open or close windows or reorder them.

Also see `:tabdo` , `:argdo` , `:bufdo` , `:cdo` , `:ldo` , `:cfdo` and `:lfdo`

`:[range]bufdo[!] {cmd}` :bufdo  
Execute `{cmd}` in each buffer in the buffer list or if `[range]` is given only for buffers for which their buffer number is in the `[range]`. It works like doing this:

```
:bfirst
:{cmd}
:bnext
:{cmd}
etc.
```

When the current file can't be `abandon` ed and the `[!]` is not present, the command fails.

When an error is detected on one buffer, further buffers will not be visited.

Unlisted buffers are skipped.

The last buffer (or where an error occurred) becomes the current buffer.

`{cmd}` can contain `|` to concatenate several commands.

`{cmd}` must not delete buffers or add buffers to the buffer list.

**Note:** While this command is executing, the Syntax autocommand event is disabled by adding it to `'eventignore'`. This considerably speeds up editing each buffer.

Also see `:tabdo` , `:argdo` , `:windo` , `:cdo` , `:ldo` , `:cfdo` and `:lfdo`

Examples:

```
:windo set nolist foldcolumn=0 | normal! zn
```

This resets the **'list'** option and disables folding in all windows.

```
:bufdo set fileencoding= | update
```

This resets the **'fileencoding'** in each buffer and writes it if this changed the buffer. The result is that all buffers will use the **'encoding'** encoding (if conversion succeeds).

9. Tag or file name under the cursor

```
window-tag
```

```
:sta :stag
```

```
:sta[g][!] [tagname]
```

Does `":tag[!] [tagname]"` and splits the window for the found tag. See also `:tag`.

```
CTRL-W]
```

```
CTRL-W_] CTRL-W_CTRL-]
```

```
CTRL-W CTRL-]
```

Split current window in two. Use identifier under cursor as a tag and jump to it in the new upper window. In Visual mode uses the Visually selected text as a tag. Make new window N high.

```
CTRL-W_g]
```

```
CTRL-W g]
```

Split current window in two. Use identifier under cursor as a tag and perform `":tselect"` on it in the new upper window. In Visual mode uses the Visually selected text as a tag. Make new window N high.

```
CTRL-W_g_CTRL-]
```

```
CTRL-W g CTRL-]
```

Split current window in two. Use identifier under cursor as a tag and perform `":tjump"` on it in the new upper window. In Visual mode uses the Visually selected text as a tag. Make new window N high.

```
CTRL-W f
```

```
CTRL-W_f CTRL-W_CTRL-F
```

```
CTRL-W CTRL-F
```

Split current window in two. Edit file name under cursor. Like `":split gf"`, but window isn't split if the file does not exist. Uses the **'path'** variable as a list of directory names where to look for the file. Also the path for current file is used to search for the file name. If the name is a hypertext link that looks like `"type://machine/path"`, only `"/path"` is used. If a count is given, the count'th matching file is edited.

```
CTRL-W F
```

```
CTRL-W_F
```

Split current window in two. Edit file name under cursor and jump to the line number following the file name. See `gF` for details on how the line number is obtained.

```
CTRL-W gf
```

```
CTRL-W_gf
```

Open a new tab page and edit the file name under the cursor. Like "tab split" and "gf", but the new tab page isn't created if the file does not exist.

**CTRL-W** gF

CTRL-W\_gF

Open a new tab page and edit the file name under the cursor and jump to the line number following the file name. Like "tab split" and "gF", but the new tab page isn't created if the file does not exist.

**CTRL-W** gt

CTRL-W\_gt

Go to next tab page, same as `gt`.

**CTRL-W** gT

CTRL-W\_gT

Go to previous tab page, same as `gT`.

Also see CTRL-W\_CTRL-I : open window for an included file that includes the keyword under the cursor.

---

## 10. The preview window

preview-window

The preview window is a special window to show (preview) another file. It is normally a small window used to show an include file or definition of a function.

{not available when compiled without the |+quickfix| feature}

There can be only one preview window (per tab page). It is created with one of the commands below. The '**previewheight**' option can be set to specify the height of the preview window when it's opened. The '**previewwindow**' option is set in the preview window to be able to recognize it. The '**winfixheight**' option is set to have it keep the same height when opening/closing other windows.

preview-popup

Alternatively, a popup window can be used by setting the '**previewpopup**' option. When set, it overrules the '**previewwindow**' and '**previewheight**' settings. The option is a comma-separated list of values:

height	maximum height of the popup
width	maximum width of the popup
highlight	highlight group of the popup (default is Pmenu)

Example:

```
:set previewpopup=height:10,width:60
```

A few peculiarities:

- If the file is in a buffer already, it will be re-used. This will allow for editing the file while it's visible in the popup window.
- No ATTENTION dialog will be used, since you can't edit the file in the popup window. However, if you later open the same buffer in a normal window, you may not notice it's edited elsewhere. And when then using ":edit" to trigger the ATTENTION and responding "A" for Abort, the preview window will become empty.

:pt :ptag

:pt[ag][!] [tagname]

Does `":tag[!] [tagname]"` and shows the found tag in a "Preview" window without changing the current buffer or cursor position. If a "Preview" window already exists, it is re-used (like a help window is). If a new one is opened, **'previewheight'** is used for the height of the window. See also `:tag` .

See below for an example. [CursorHold-example](#)

Small difference from `:tag` : When `[tagname]` is equal to the already displayed tag, the position in the matching tag list is not reset. This makes the `CursorHold` example work after a `:ptnext` .

**CTRL-W z** CTRL-W\_z  
**CTRL-W CTRL-Z** CTRL-W\_CTRL-Z :pc :pclose  
`:pc[lose][!]` Close any "Preview" window currently open. When the **'hidden'** option is set, or when the buffer was changed and the `[!]` is used, the buffer becomes hidden (unless there is another window editing it). The command fails if any "Preview" buffer cannot be closed. See also `:close` .

:pp :ppop  
`:[count]pp[op][!]` Does `":[count]pop[!]"` in the preview window. See `:pop` and `:ptag` .

**CTRL-W }** CTRL-W\_}  
Use identifier under cursor as a tag and perform a `:ptag` on it. Make the new Preview window (if required) N high. If N is not given, **'previewheight'** is used.

**CTRL-W g }** CTRL-W\_g}  
Use identifier under cursor as a tag and perform a `:ptjump` on it. Make the new Preview window (if required) N high. If N is not given, **'previewheight'** is used.

:pb :pbuffer  
`:[N]pb[uffer][!] [+cmd] [N]` Edit buffer [N] from the buffer list in the preview window. If [N] is not given, the current buffer remains being edited. See `:buffer-!` for `[!]`. This will also edit a buffer that is not in the buffer list, without setting the **'buflisted'** flag. The notation with single quotes does not work here, ``:pbuffer 12'345'`` uses `12'345'` as a buffer name. Also see `+cmd` .

:ped :pedit  
`:ped[it][!] [++opt] [+cmd] {file}` Edit `{file}` in the preview window. The preview window is opened like with `:ptag` . The current window and cursor position isn't changed. Useful example:

`:pedit +/putc /usr/include/stdio.h`

Also see `++opt` and `+cmd` .

```

:ps :psearch
:[range]ps[earch][!] [count] [/]pattern[/]
 Works like :ijump but shows the found match in the preview
 window. The preview window is opened like with :ptag . The
 current window and cursor position isn't changed. Useful
 example:
 :psearch popen
 Like with the :ptag command, you can use this to
 automatically show information about the word under the
 cursor. This is less clever than using :ptag , but you don't
 need a tags file and it will also find matches in system
 include files. Example:
:au! CursorHold *.*[ch] ++nested exe "silent! psearch " .. expand("<word>")
 Warning: This can be slow.

```

Example

CursorHold-example

```

:au! CursorHold *.*[ch] ++nested exe "silent! ptag " .. expand("<word>")

```

This will cause a ":ptag" to be executed for the keyword under the cursor, when the cursor hasn't moved for the time set with 'updateime'. The "nested" makes other autocommands be executed, so that syntax highlighting works in the preview window. The "silent!" avoids an error message when the tag could not be found. Also see [CursorHold](#) . To disable this again:

```

:au! CursorHold

```

A nice addition is to highlight the found tag, avoid the ":ptag" when there is no word under the cursor, and a few other things:

```

:au! CursorHold *.*[ch] ++nested call PreviewWord()
:func PreviewWord()
: if &previewwindow " don't do this in the preview window
: return
: endif
: let w = expand("<word>") " get the word under cursor
: if w =~ '\a' " if the word contains a letter
:
: " Delete any existing highlight before showing another tag
: silent! wincmd P " jump to preview window
: if &previewwindow " if we really get there...
: match none " delete existing highlight
: wincmd p " back to old window
: endif
:
: " Try displaying a matching tag for the word under the cursor
: try
: exe "ptag " .. w
: catch
: return
: endtry
:
: silent! wincmd P " jump to preview window
: if &previewwindow " if we really get there...

```

```

: if has("folding")
: silent! .foldopen " don't want a closed fold
: endif
: call search("$", "b") " to end of previous line
: let w = substitute(w, '\\', '\\\\', "")
: call search('\<\V' .. w .. '\>') " position cursor on match
: " Add a match highlight to the word at this position
: hi previewWord term=bold ctermfg=green guibg=green
: exe 'match previewWord "\%" .. line(".") .. '\%' .. col(".") .. 'c\k*'
: wincmd p " back to old window
: endif
: endif
:endifun

```

---

## 11. Using hidden buffers

buffer-hidden

A hidden buffer is not displayed in a window, but is still loaded into memory. This makes it possible to jump from file to file, without the need to read or write the file every time you get another buffer in a window.

:buffer-!

If the option **'hidden'** ('hid') is set, abandoned buffers are kept for all commands that start editing another file: ":edit", ":next", ":tag", etc. The commands that move through the buffer list sometimes make the current buffer hidden although the **'hidden'** option is not set. This happens when a buffer is modified, but is forced (with '!') to be removed from a window, and **'autowrite'** is off or the buffer can't be written.

You can make a hidden buffer not hidden by starting to edit it with any command, or by deleting it with the ":bdelete" command.

The **'hidden'** is global, it is used for all buffers. The **'bufhidden'** option can be used to make an exception for a specific buffer. It can take these values:

<code>&lt;empty&gt;</code>	Use the value of <b>'hidden'</b> .
<code>hide</code>	Hide this buffer, also when <b>'hidden'</b> is not set.
<code>unload</code>	Don't hide but unload this buffer, also when <b>'hidden'</b> is set.
<code>delete</code>	Delete the buffer.

hidden-quit

When you try to quit Vim while there is a hidden, modified buffer, you will get an error message and Vim will make that buffer the current buffer. You can then decide to write this buffer (":wq") or quit without writing (":q!"). Be careful: there may be more hidden, modified buffers!

A buffer can also be unlisted. This means it exists, but it is not in the list of buffers. [unlisted-buffer](#)

```

:files[!] [flags] :files
:buffers[!] [flags] :buffers :ls
:ls[!] [flags]

```

Show all buffers. Example:

```
1 #h "/test/text" line 1
2u "asdf" line 0
3 %a + "version.c" line 1
```

When the [!] is included the list will show unlisted buffers (the term "unlisted" is a bit confusing then...).

Each buffer has a unique number. That number will not change, thus you can always go to a specific buffer with ":buffer N" or "N **CTRL-^**", where N is the buffer number.

For the file name these special values are used:

```
[Prompt] prompt-buffer
[Popup] buffer of a popup-window
[Scratch] 'buftype' is "nofile"
[No Name] no file name specified
```

For a `terminal-window` buffer the status is used.

Indicators (chars in the same column are mutually exclusive):

```
u an unlisted buffer (only displayed when [!] is used)
 unlisted-buffer
% the buffer in the current window
the alternate buffer for ":e #" and CTRL-^
a an active buffer: it is loaded and visible
h a hidden buffer: It is loaded, but currently not
 displayed in a window hidden-buffer
- a buffer with 'modifiable' off
= a readonly buffer
R a terminal buffer with a running job
F a terminal buffer with a finished job
? a terminal buffer without a job: `:terminal NONE`
+ a modified buffer
x a buffer with read errors
```

[flags] can be a combination of the following characters, which restrict the buffers to be listed:

```
+ modified buffers
- buffers with 'modifiable' off
= readonly buffers
a active buffers
u unlisted buffers (overrides the "!")
h hidden buffers
x buffers with a read error
% current buffer
alternate buffer
R terminal buffers with a running job
F terminal buffers with a finished job
? terminal buffers without a job: `:terminal NONE`
t show time last used and sort buffers
```

Combining flags means they are "and"ed together, e.g.:

```
h+ hidden buffers which are modified
a+ active buffers which are modified
```

When using `:filter` the pattern is matched against the displayed buffer name, e.g.:

```
filter /\.vim/ ls
```

`:bad` `:badd`

`:bad[d] [+lnum] {fname}`

Add file name `{fname}` to the buffer list, without loading it, if it wasn't listed yet. If the buffer was previously deleted, not wiped, it will be made listed again. If "lnum" is specified, the cursor will be positioned at that line when the buffer is first entered. **Note** that other commands after the + will be ignored.

`:balt`

`:balt [+lnum] {fname}`

Like `:badd`` and also set the alternate file for the current window to `{fname}`.

`:[N]bd[elete][!]`

`:bd` `:bdel` `:bdelete` E516

`:bd[elete][!] [N]`

Unload buffer [N] (default: current buffer) and delete it from the buffer list. If the buffer was changed, this fails, unless when [!] is specified, in which case changes are lost. The file remains unaffected. Any windows for this buffer are closed. If buffer [N] is the current buffer, another buffer will be displayed instead. This is the most recent entry in the jump list that points into a loaded buffer. Actually, the buffer isn't completely deleted, it is removed from the buffer list `unlisted-buffer` and option values, variables and mappings/abbreviations for the buffer are cleared. Examples:

```
!.,,$-bdelete " delete buffers from the current one to
 " last but one
:%bdelete " delete all buffers
```

`:bdelete[!] {bufname}`

E93 E94

Like `":bdelete[!] [N]"`, but buffer given by name, see `{bufname}` .

`:bdelete[!] N1 N2 ...`

Do `":bdelete[!]"` for buffer N1, N2, etc. The arguments can be buffer numbers or buffer names (but not buffer names that are a number). Insert a backslash before a space in a buffer name.

`:N,Mbdelete[!]` Do `":bdelete[!]"` for all buffers in the range N to M

`inclusive` .

`:[N]bw[ipeout][!]`

`:bw` `:bwipe` `:bwipeout` E517

`:bw[ipeout][!] {bufname}`

`:N,Mbw[ipeout][!]`

`:bw[ipeout][!] N1 N2 ...`

Like `:bdelete` , but really delete the buffer. Everything related to the buffer is lost. All marks in this buffer become invalid, option settings are lost, the jumplist and tagstack data will be purged, etc. Don't use this unless you know what you are doing. Examples:

```
:.+,$bwipeout " wipe out all buffers after the current
 " one
:%bwipeout " wipe out all buffers
```

```
:[N]bun[load][!] :bun :bunload E515
:bun[load][!] [N]
```

Unload buffer [N] (default: current buffer). The memory allocated for this buffer will be freed. The buffer remains in the buffer list.

If the buffer was changed, this fails, unless when [!] is specified, in which case the changes are lost.

Any windows for this buffer are closed. If buffer [N] is the current buffer, another buffer will be displayed instead.

This is the most recent entry in the jump list that points into a loaded buffer.

```
:bunload[!] {bufname}
```

Like `":bunload[!] [N]"`, but buffer given by name. Also see `{bufname}` .

```
:N,Mbunload[!] Do ":bunload[!]" for all buffers in the range N to M
 inclusive .
```

```
:bunload[!] N1 N2 ...
```

Do `":bunload[!]"` for buffer N1, N2, etc. The arguments can be buffer numbers or buffer names (but not buffer names that are a number). Insert a backslash before a space in a buffer name.

```
:[N]b[uffer][!] [+cmd] [N] :b :bu :buf :buffer E86
```

Edit buffer [N] from the buffer list. If [N] is not given, the current buffer remains being edited. See `:buffer-!` for [!]. This will also edit a buffer that is not in the buffer list, without setting the `'buflisted'` flag.

The notation with single quotes does not work here, ``:buf 12'345'`` uses `12'345'` as a buffer name.

Also see `+cmd` .

```
:[N]b[uffer][!] [+cmd] {bufname} {bufname}
```

Edit buffer for `{bufname}` from the buffer list. A partial name also works, so long as it is unique in the list of buffers.

**Note** that a buffer whose name is a number cannot be referenced by that name; use the buffer number instead.

Insert a backslash before a space in a buffer name.

See `:buffer-!` for [!].

This will also edit a buffer that is not in the buffer list, without setting the `'buflisted'` flag.

Also see `+cmd` .

`:[N]sb[uffer] [+cmd] [N]` `:sb` `:sbuffer`  
Split window and edit buffer [N] from the buffer list. If [N] is not given, the current buffer is edited. Respects the "useopen" setting of '`switchbuf`' when splitting. This will also edit a buffer that is not in the buffer list, without setting the '`buflisted`' flag.  
Also see `+cmd` .

`:[N]sb[uffer] [+cmd] {bufname}`  
Split window and edit buffer for {bufname} from the buffer list. This will also edit a buffer that is not in the buffer list, without setting the '`buflisted`' flag.  
**Note:** If what you want to do is split the buffer, make a copy under another name, you can do it this way:  
`:w foobar | sp #`  
Also see `+cmd` .

`:[N]bn[ext][!]` `[+cmd]` [N] `:bn` `:bnext` E87  
Go to [N]th next buffer in buffer list. [N] defaults to one. Wraps around the end of the buffer list.  
See `:buffer-!` for [!].  
Also see `+cmd` .  
If you are in a help buffer, this takes you to the next help buffer (if there is one). Similarly, if you are in a normal (non-help) buffer, this takes you to the next normal buffer. This is so that if you have invoked help, it doesn't get in the way when you're browsing code/text buffers. The next three commands also work like this.

`:[N]sbn[ext]` `[+cmd]` [N] `:sbn` `:sbnext`  
Split window and go to [N]th next buffer in buffer list. Wraps around the end of the buffer list. Uses '`switchbuf`'.  
Also see `+cmd` .

`:[N]bN[ext][!]` `[+cmd]` [N] `:bN` `:bNext` `:bp` `:bprevious` E88  
`:[N]bp[revious][!]` `[+cmd]` [N]  
Go to [N]th previous buffer in buffer list. [N] defaults to one. Wraps around the start of the buffer list.  
See `:buffer-!` for [!] and '`switchbuf`'.  
Also see `+cmd` .

`:[N]sbN[ext]` `[+cmd]` [N] `:sbN` `:sbNext` `:sbp` `:sbprevious`  
`:[N]sbp[revious]` `[+cmd]` [N]  
Split window and go to [N]th previous buffer in buffer list. Wraps around the start of the buffer list.  
Uses '`switchbuf`'.  
Also see `+cmd` .

`:br[ewind][!]` `[+cmd]` `:br` `:bre` `:brewind`  
Go to first buffer in buffer list. If the buffer list is empty, go to the first unlisted buffer.

See `:buffer-!` for `[!]`.

`:bf[irst] [+cmd]` `:bf` `:bfirst`

Same as `:brewind` .  
Also see `+cmd` .

`:sbr[ewind] [+cmd]` `:sbr` `:sbrewind`

Split window and go to first buffer in buffer list. If the buffer list is empty, go to the first unlisted buffer. Respects the `'switchbuf'` option. Also see `+cmd` .

`:sbf[irst] [+cmd]` `:sbf` `:sbfirst`

Same as `":sbrewind"`.

`:bl[ast][!] [+cmd]` `:bl` `:blast`

Go to last buffer in buffer list. If the buffer list is empty, go to the last unlisted buffer. See `:buffer-!` for `[!]`.

`:sbl[ast] [+cmd]` `:sbl` `:sblast`

Split window and go to last buffer in buffer list. If the buffer list is empty, go to the last unlisted buffer. Respects `'switchbuf'` option.

`:[N]bm[odified][!] [+cmd] [N]` `:bm` `:bmodified` E84

Go to `[N]`th next modified buffer. **Note:** this command also finds unlisted buffers. If there is no modified buffer the command fails.

`:[N]sbm[odified] [+cmd] [N]` `:sbm` `:sbmodified`

Split window and go to `[N]`th next modified buffer. Respects `'switchbuf'` option. **Note:** this command also finds buffers not in the buffer list.

`:[N]unh[ide] [N]` `:unh` `:unhide` `:sun` `:sunhide`

`:[N]sun[hide] [N]`

Rearrange the screen to open one window for each loaded buffer in the buffer list. When a count is given, this is the maximum number of windows to open.

`:[N]ba[ll] [N]` `:ba` `:ball` `:sba` `:sball`

`:[N]sba[ll] [N]` Rearrange the screen to open one window for each buffer in the buffer list. When a count is given, this is the maximum number of windows to open. `'winheight'` also limits the number of windows opened (`'winwidth'` if `:vertical` was prepended). Buf/Win Enter/Leave autocommands are not executed for the new windows here, that's only done when they are really entered. When the `:tab` modifier is used new windows are opened in a new tab, up to `'tabpagemax'`.

**Note:** All the commands above that start editing another buffer, keep the `'readonly'` flag as it was. This differs from the `":edit"` command, which sets the `'readonly'` flag each time the file is read.

---

---

## 12. Special kinds of buffers

### special-buffers

Instead of containing the text of a file, buffers can also be used for other purposes. A few options can be set to change the behavior of a buffer:

**'bufhidden'** what happens when the buffer is no longer displayed in a window.  
**'buftype'** what kind of a buffer this is  
**'swapfile'** whether the buffer will have a swap file  
**'buflisted'** buffer shows up in the buffer list

A few useful kinds of a buffer:

**quickfix** Used to contain the error list or the location list. See `:cwindow` and `:lwindow`. This command sets the **'buftype'** option to "quickfix". You are not supposed to change this! **'swapfile'** is off.

**help** Contains a help file. Will only be created with the `:help` command. The flag that indicates a help buffer is internal and can't be changed. The **'buflisted'** option will be reset for a help buffer.

**terminal** A terminal window buffer, see `terminal`. The contents cannot be read or changed until the job ends.

**directory** Displays directory contents. Can be used by a file explorer plugin. The buffer is created with these settings:

```
:setlocal buftype=nowrite
:setlocal bufhidden=delete
:setlocal noswapfile
```

The buffer name is the name of the directory and is adjusted when using the `:cd` command.

### scratch-buffer

**scratch** Contains text that can be discarded at any time. It is kept when closing the window, it must be deleted explicitly. Settings:

```
:setlocal buftype=nofile
:setlocal bufhidden=hide
:setlocal noswapfile
```

The buffer name can be used to identify the buffer, if you give it a meaningful name.

### unlisted-buffer

**unlisted** The buffer is not in the buffer list. It is not used for normal editing, but to show a help file, remember a file name or marks. The `":bdelete"` command will also set this option, thus it doesn't completely delete the buffer. Settings:

```
:setlocal nobuflisted
```

Editing with windows in multiple tab pages. [tab-page](#) [tabpage](#)

The commands which have been added to use multiple tab pages are explained here. Additionally, there are explanations for commands that work differently when used in combination with more than one tab page.

- 1. Introduction [tab-page-intro](#)
- 2. Commands [tab-page-commands](#)
- 3. Other items [tab-page-other](#)
- 4. Setting **'tabline'** [setting-tabline](#)
- 5. Setting **'guitablabel'** [setting-guitablabel](#)

{not able to use multiple tab pages when the `+windows` feature was disabled at compile time}

---

## 1. Introduction [tab-page-intro](#)

A tab page holds one or more windows. You can easily switch between tab pages, so that you have several collections of windows to work on different things.

Usually you will see a list of labels at the top of the Vim window, one for each tab page. With the mouse you can click on the label to jump to that tab page. There are other ways to move between tab pages, see below.

Most commands work only in the current tab page. That includes the `CTRL-W` commands, `:windo`, `:all` and `:ball` (when not using the `:tab` modifier). The commands that are aware of other tab pages than the current one are mentioned below.

Tabs are also a nice way to edit a buffer temporarily without changing the current window layout. Open a new tab page, do whatever you want to do and close the tab page.

---

## 2. Commands [tab-page-commands](#)

### OPENING A NEW TAB PAGE:

When starting Vim `"vim -p filename ..."` opens each file argument in a separate tab page (up to **'tabpagemax'**). See `-p`

A double click with the mouse in the non-GUI tab pages line opens a new, empty tab page. It is placed left of the position of the click. The first click may select another tab page first, causing an extra screen update.

This also works in a few GUI versions, esp. Win32 and Motif. But only when

clicking right of the labels.

In the GUI tab pages line you can use the right mouse button to open menu.  
`tabline-menu` .

For the related autocommands see `tabnew-autocmd` .

```
:[count]tabe[dit] :tabe :tabedit :tabnew
:[count]tabnew
```

Open a new tab page with an empty window, after the current tab page. If [count] is given the new tab page appears after the tab page [count] otherwise the new tab page will appear after the current one.

```
 :tabnew " opens tabpage after the current one
 :.tabnew " as above
 :+tabnew " opens tabpage after the next tab page
 " note: it is one further than :tabnew
 :-tabnew " opens tabpage before the current one
 :@tabnew " opens tabpage before the first one
 :$tabnew " opens tabpage after the last one
```

```
:[count]tabe[dit] [++opt] [+cmd] {file}
:[count]tabnew [++opt] [+cmd] {file}
 Open a new tab page and edit {file}, like with :edit .
 For [count] see :tabnew above.
```

```
:[count]tabf[ind] [++opt] [+cmd] {file} :tabf :tabfind
 Open a new tab page and edit {file} in 'path', like with
 :find . For [count] see :tabnew above.
```

```
:[count]tab {cmd} :tab
 Execute {cmd} and when it opens a new window open a new tab
 page instead. Doesn't work for :diffsplit , :diffpatch ,
 :execute and :normal .
 If [count] is given the new tab page appears after the tab
 page [count] otherwise the new tab page will appear after the
 current one.
```

Examples:

```
 :tab split " opens current buffer in new tab page
 :tab help gt " opens tab page with help for "gt"
 :.tab help gt " as above
 :+tab help " opens tab page with help after the next
 " tab page
 :-tab help " opens tab page with help before the
 " current one
 :@tab help " opens tab page with help before the
 " first one
 :$tab help " opens tab page with help after the last
 " one
```

**CTRL-W gf** Open a new tab page and edit the file name under the cursor.  
See `CTRL-W_gf` .

**CTRL-W gF** Open a new tab page and edit the file name under the cursor

and jump to the line number following the file name.  
See `CTRL-W_gF` .

#### CLOSING A TAB PAGE:

Closing the last window of a tab page closes the tab page too, unless there is only one tab page.

Using the mouse: If the tab page line is displayed you can click in the "X" at the top right to close the current tab page. A custom `'tabline'` may show something else.

```
 :tabc :tabclose
:tabc[lose][!] Close current tab page.
 This command fails when:
 - There is only one tab page on the screen. E784
 - When 'hidden' is not set, [!] is not used, a buffer has
 changes, and there is no other window on this buffer.
 Changes to the buffer are not written and won't get lost, so
 this is a "safe" command.
 :tabclose " close the current tab page

:{count}tabc[lose][!]
:tabc[lose][!] {count}
 Close tab page {count}. Fails in the same way as `:tabclose`
 above.
 :-tabclose " close the previous tab page
 :+tabclose " close the next tab page
 :1tabclose " close the first tab page
 :$tabclose " close the last tab page
 :tabclose -2 " close the 2nd previous tab page
 :tabclose + " close the next tab page
 :tabclose 3 " close the third tab page
 :tabclose $ " close the last tab page
 :tabclose # " close the last accessed tab page
```

When a tab is closed the next tab page will become the current one. This behaviour can be customized using the `'tabclose'` option.

```
 :tabo :tabonly
:tabo[nly][!] Close all other tab pages.
 When the 'hidden' option is set, all buffers in closed windows
 become hidden.
 When 'hidden' is not set, and the 'autowrite' option is set,
 modified buffers are written. Otherwise, windows that have
 buffers that are modified are not removed, unless the [!] is
 given, then they become hidden. But modified buffers are
 never abandoned, so changes cannot get lost.
 :tabonly " close all tab pages except the current
 " one

:{count}tabo[nly][!]
:tabo[nly][!] {count}
 Close all tab pages except {count} one.
```

```

 :.tabonly " as above
 :-tabonly " close all tab pages except the previous
 " one
 :+tabonly " close all tab pages except the next one
 :1tabonly " close all tab pages except the first one
 :$tabonly " close all tab pages except the last one
 :tabonly - " close all tab pages except the previous
 " one
 :tabonly +2 " close all tab pages except the two next
 " one
 :tabonly 1 " close all tab pages except the first one
 :tabonly $ " close all tab pages except the last one
 :tabonly # " close all tab pages except the last
 " accessed one

```

#### SWITCHING TO ANOTHER TAB PAGE:

Using the mouse: If the tab page line is displayed you can click in a tab page label to switch to that tab page. Click where there is no label to go to the next tab page. `'tabline'`

```

:tabn[ext] :tabn :tabnext gt
<C-PageDown> CTRL-<PageDown> <C-PageDown>
gt i_CTRL-<PageDown> i_<C-PageDown>
 Go to the next tab page. Wraps around from the last to the
 first one.

```

```

:{count}tabn[ext]
:tabn[ext] {count}
 Go to tab page {count}. The first tab page has number one.
 :-tabnext " go to the previous tab page
 :+tabnext " go to the next tab page
 :+2tabnext " go to the two next tab page
 :1tabnext " go to the first tab page
 :$tabnext " go to the last tab page
 :tabnext $ " as above
 :tabnext # " go to the last accessed tab page
 :tabnext - " go to the previous tab page
 :tabnext -1 " as above
 :tabnext + " go to the next tab page
 :tabnext +1 " as above

```

```

{count}<C-PageDown>
{count}gt Go to tab page {count}. The first tab page has number one.

```

```

:tabp[revious] :tabp :tabprevious gT :tabN
:tabN[ext] :tabNext CTRL-<PageUp>
<C-PageUp> <C-PageUp> i_CTRL-<PageUp> i_<C-PageUp>
gT Go to the previous tab page. Wraps around from the first one
 to the last one.

```

```

:tabp[revious] {count}

```

```

:tabN[ext] {count}
{count}<C-PageUp>
{count}gT Go {count} tab pages back. Wraps around from the first one
 to the last one. Note that the use of {count} is different
 from :tabnext , where it is used as the tab page number.

```

```

:tabr[ewind] :tabfir :tabfirst :tabr :tabrewind
:tabfir[st] Go to the first tab page.

```

```

:tabl[ast] Go to the last tab page.
 :tabl :tablast

```

```

<C-Tab>
g<Tab>
CTRL-W g<Tab> Go to the last accessed tab page.
 g<Tab> CTRL-W_g<Tab> <C-Tab>

```

Other commands:

```

:tabs List the tab pages and the windows they contain.
 Shows a ">" for the current window.
 Shows a "+" for modified buffers.
 For example:

```

```

 Tab page 1
 + tabpage.txt
 ex_docmd.c
 Tab page 2
 > main.c

```

REORDERING TAB PAGES:

```

:tabm[ove] [N] :tabm :tabmove
:[N]tabm[ove]
 Move the current tab page to after tab page N. Use zero to
 make the current tab page the first one. N is counted before
 the move, thus if the second tab is the current one,
 `:tabmove 1` and `:tabmove 2` have no effect.
 Without N the tab page is made the last one.

```

```

 :.tabmove " do nothing
 :-tabmove " move the tab page to the left
 :+tabmove " move the tab page to the right
 :@tabmove " move the tab page to the first
 :tabmove 0 " as above
 :tabmove " move the tab page to the last
 :$tabmove " as above
 :tabmove $ " as above
 :tabmove # " move the tab page after the last accessed
 " tab page

```

```

:tabm[ove] +[N]
:tabm[ove] -[N]
 Move the current tab page N places to the right (with +) or to
 the left (with -).

```

```

 :tabmove - " move the tab page to the left

```

```
:tabmove -1 " as above
:tabmove + " move the tab page to the right
:tabmove +1 " as above
```

Note that although it is possible to move a tab behind the N-th one by using :Ntabmove. And move it by N places by using :+Ntabmove. For clarification what +N means in this context see [\[range\]](#) .

LOOPING OVER TAB PAGES:

```
:[range]tabd[o] {cmd} :tabd :tabdo
Execute {cmd} in each tab page or if [range] is given only in
tab pages which tab page number is in the [range]. It works
like doing this:
 :tabfirst
 :{cmd}
 :tabnext
 :{cmd}
 etc.
```

This only operates in the current window of each tab page.

When an error is detected on one tab page, further tab pages will not be visited.

The last tab page (or where an error occurred) becomes the current tab page.

{cmd} can contain '|' to concatenate several commands.

{cmd} must not open or close tab pages or reorder them.

Also see [:windo](#) , [:argdo](#) , [:bufdo](#) , [:cdo](#) , [:ldo](#) , [:cfdo](#) and [:lfdo](#)

---

### 3. Other items

[tab-page-other](#)

[tabline-menu](#)

The GUI tab pages line has a popup menu. It is accessed with a right click. The entries are:

Close	Close the tab page under the mouse pointer. The current one if there is no label under the mouse pointer.
New Tab	Open a tab page, editing an empty buffer. It appears to the left of the mouse pointer.
Open Tab...	Like "New Tab" and additionally use a file selector to select a file to edit.

Diff mode works per tab page. You can see the diffs between several files within one tab page. Other tab pages can show differences between other files.

Variables local to a tab page start with "t:". [tabpage-variable](#)

Currently there is only one option local to a tab page: ['cmdheight'](#).

#### tabnew-autocmd

The TabLeave and TabEnter autocommand events can be used to do something when switching from one tab page to another. The exact order depends on what you are doing. When creating a new tab page this works as if you create a new window on the same buffer and then edit another buffer. Thus ":tabnew" triggers:

WinLeave	leave current window
TabLeave	leave current tab page
WinEnter	enter window in new tab page
TabEnter	enter new tab page
BufLeave	leave current buffer
BufEnter	enter new empty buffer

When switching to another tab page the order is:

```
BufLeave
WinLeave
TabLeave
TabEnter
WinEnter
BufEnter
```

---

#### 4. Setting 'tabline'

#### setting-tabline

The 'tabline' option specifies what the line with tab pages labels looks like. It is only used when there is no GUI tab line.

You can use the 'showtabline' option to specify when you want the line with tab page labels to appear: never, when there is more than one tab page or always.

The highlighting of the tab pages line is set with the groups TabLine, TabLineSel and TabLineFill. `hl-TabLine` `hl-TabLineSel` `hl-TabLineFill`

A "+" will be shown for a tab page that has a modified window. The number of windows in a tabpage is also shown. Thus "3+" means three windows and one of them has a modified buffer.

The 'tabline' option allows you to define your preferred way to tab pages labels. This isn't easy, thus an example will be given here.

For basics see the 'statusline' option. The same items can be used in the 'tabline' option. Additionally, the `tabpagebuflist()`, `tabpagenr()` and `tabpagewinnr()` functions are useful.

Since the number of tab labels will vary, you need to use an expression for the whole option. Something like:

```
:set tabline=%!MyTabLine()
```

Then define the MyTabLine() function to list all the tab pages labels. A convenient method is to split it in two parts: First go over all the tab pages and define labels for them. Then get the label for each tab page.

```
function MyTabLine()
```

```

let s = ''
for i in range(tabpagenr('$'))
 " select the highlighting
 if i + 1 == tabpagenr()
 let s .= '%#TabLineSel#'
 else
 let s .= '%#TabLine#'
 endif

 " set the tab page number (for mouse clicks)
 let s .= '%' .. (i + 1) .. 'T'

 " the label is made by MyTabLabel()
 let s .= ' %{MyTabLabel(' .. (i + 1) .. ')} '
endfor

" after the last tab fill with TabLineFill and reset tab page nr
let s .= '%#TabLineFill#%T'

" right-align the label to close the current tab page
if tabpagenr('$') > 1
 let s .= '%=%#TabLine#%999Xclose'
endif

return s
endfunction

```

Now the `MyTabLabel()` function is called for each tab page to get its label.

```

function MyTabLabel(n)
 let buflist = tabpagebuflist(a:n)
 let winnr = tabpagewinnr(a:n)
 return bufname(buflist[winnr - 1])
endfunction

```

This is just a simplistic example that results in a tab pages line that resembles the default, but without adding a + for a modified buffer or truncating the names. You will want to reduce the width of labels in a clever way when there is not enough room. Check the **'columns'** option for the space available.

---

## 5. Setting **'guitablabel'** setting-guitablabel

When the GUI tab pages line is displayed, **'guitablabel'** can be used to specify the label to display for each tab page. Unlike **'tabline'**, which specifies the whole tab pages line at once, **'guitablabel'** is used for each label separately.

**'guitabtooltip'** is very similar and is used for the tooltip of the same label. This only appears when the mouse pointer hovers over the label, thus it usually is longer. Only supported on some systems though.

See the **'statusline'** option for the format of the value.

The "%N" item can be used for the current tab page number. The `v:lnum` variable is also set to this number when the option is evaluated. The items that use a file name refer to the current window of the tab page.

**Note** that syntax highlighting is not used for the option. The %T and %X items are also ignored.

A simple example that puts the tab page number and the buffer name in the label:

```
:set guitablabel=%N\ %f
```

An example that resembles the default `'guitablabel'`: Show the number of windows in the tab page and a '+' if there is a modified buffer:

```
function GuiTabLabel()
 let label = ''
 let bufnrlist = tabpagebuflist(v:lnum)

 " Add '+' if one of the buffers in the tab page is modified
 for bufnr in bufnrlist
 if getbufvar(bufnr, "&modified")
 let label = '+'
 break
 endif
 endfor

 " Append the number of windows in the tab page if more than one
 let wincount = tabpagewinnr(v:lnum, '$')
 if wincount > 1
 let label .= wincount
 endif
 if label != ''
 let label .= ' '
 endif

 " Append the buffer name
 return label .. bufname(bufnrlist[tabpagewinnr(v:lnum) - 1])
endfunction

set guitablabel=%{GuiTabLabel()}
```

**Note** that the function must be defined before setting the option, otherwise you get an error message for the function not being known.

If you want to fall back to the default label, return an empty string.

If you want to show something specific for a tab page, you might want to use a tab page local variable. `t:var`

## Spell checking

spell

- |                              |                   |
|------------------------------|-------------------|
| 1. Quick start               | spell-quickstart  |
| 2. Remarks on spell checking | spell-remarks     |
| 3. Generating a spell file   | spell-mkspell     |
| 4. Spell file format         | spell-file-format |

{not available when the |+syntax| feature has been disabled at compile time}

**Note:** There also is a vimspell plugin. If you have it you can do ":help vimspell" to find about it. But you will probably want to get rid of the plugin and use the '**spell**' option instead, it works better.

- 
- |                |                  |      |
|----------------|------------------|------|
| 1. Quick start | spell-quickstart | E756 |
|----------------|------------------|------|

This command switches on spell checking:

```
:setlocal spell spelllang=en_us
```

This switches on the '**spell**' option and specifies to check for US English.

The words that are not recognized are highlighted with one of these:

SpellBad	word not recognized	hl-SpellBad
SpellCap	word not capitalised	hl-SpellCap
SpellRare	rare word	hl-SpellRare
SpellLocal	wrong spelling for selected region	hl-SpellLocal

Vim only checks words for spelling, there is no grammar check.

If the '**mousemodel**' option is set to "popup" and the cursor is on a badly spelled word or it is "popup\_setpos" and the mouse pointer is on a badly spelled word, then the popup menu will contain a submenu to replace the bad word. **Note:** this slows down the appearance of the popup menu. **Note** for GTK: don't release the right mouse button until the menu appears, otherwise it won't work.

To search for the next misspelled word:

]	Move to next misspelled word after the cursor. A count before the command can be used to repeat. ' <b>wrapsan</b> ' applies.
---	------------------------------------------------------------------------------------------------------------------------------------

[	Like "]" but search backwards, find the misspelled word before the cursor. Doesn't recognize words split over two lines, thus may stop at words that are
---	----------------------------------------------------------------------------------------------------------------------------------------------------------

not highlighted as bad. Does not stop at word with missing capital at the start of a line.

]S Like "]s" but only stop at bad words, not at rare words or words for another region.

[S Like "]S" but search backwards.

]r Move to next "rare" word after the cursor. A count before the command can be used to repeat. **'wrapscan'** applies.

[r Like "]r" but search backwards, find the "rare" word before the cursor. Doesn't recognize words split over two lines, thus may stop at words that are not highlighted as rare.

To add words to your own word list:

zg Add word under the cursor as a good word to the first name in **'spellfile'**. A count may precede the command to indicate the entry in **'spellfile'** to be used. A count of two uses the second entry.

In Visual mode the selected characters are added as a word (including white space!). When the cursor is on text that is marked as badly spelled then the marked text is used. Otherwise the word under the cursor, separated by non-word characters, is used.

If the word is explicitly marked as bad word in another spell file the result is unpredictable.

zG Like "zg" but add the word to the internal word list **internal-wordlist** .

zw Like "zg" but mark the word as a wrong (bad) word. If the word already appears in **'spellfile'** it is turned into a comment line. See **spellfile-cleanup** for getting rid of those.

zW Like "zw" but add the word to the internal word list **internal-wordlist** .

```

zuw zug zuW
zug Undo zw and zg , remove the word from the entry in
 'spellfile'. Count used as with zg .

zuW zuG zuW
zuG Undo zW and zG , remove the word from the internal
 word list. Count used as with zg .

 :spe :spellgood E1280
:[count]spe[llgood] {word}
Add {word} as a good word to 'spellfile', like with
zg . Without count the first name is used, with a
count of two the second entry, etc.

:spe[llgood]! {word} Add {word} as a good word to the internal word list,
like with zG .

 :spellw :spellwrong
:[count]spellw[rong] {word}
Add {word} as a wrong (bad) word to 'spellfile', as
with zw . Without count the first name is used, with
a count of two the second entry, etc.

:spellw[rong]! {word} Add {word} as a wrong (bad) word to the internal word
list, like with zW .

 :spellra :spellrare
:[count]spellra[re] {word}
Add {word} as a rare word to 'spellfile', similar to
zw . Without count the first name is used, with
a count of two the second entry, etc.

There are no normal mode commands to mark words as
rare as this is a fairly uncommon command and all
intuitive commands for this are already taken. If you
want you can add mappings with e.g.:
nnoemap z? :exe ':spellrare ' .. expand('<cWORD>')<CR>
nnoemap z/ :exe ':spellrare! ' .. expand('<cWORD>')<CR>
:sPELLundo , zuw , or zuW can be used to undo this.

:spellra[re]! {word} Add {word} as a rare word to the internal word
list, similar to zW .

:[count]spellu[ndo] {word} :spellu :spellundo
Like zuw . [count] used as with :spellgood .

:spellu[ndo]! {word} Like zuW . [count] used as with :spellgood .

```

After adding a word to **'spellfile'** with the above commands its associated ".spl" file will automatically be updated and reloaded. If you change **'spellfile'** manually you need to use the `:mkspell` command. This sequence of commands mostly works well:

```
:edit <file in 'spellfile'>
```

(make changes to the spell file)  
`:mkspell! %`

More details about the '**spellfile**' format below [spell-wordlist-format](#) .

The internal word list is used for all buffers where '**spell**' is set. It is not stored, it is lost when you exit Vim. It is also cleared when '**encoding**' is set.

Finding suggestions for bad words:

`z=` For the word under/after the cursor suggest correctly spelled words. This also works to find alternatives for a word that is not highlighted as a bad word, e.g., when the word after it is bad. In Visual mode the highlighted text is taken as the word to be replaced. The results are sorted on similarity to the word being replaced. This may take a long time. Hit **CTRL-C** when you get bored.

If the command is used without a count the alternatives are listed and you can enter the number of your choice or press `<Enter>` if you don't want to replace. You can also use the mouse to click on your choice (only works if the mouse can be used in Normal mode and when there are no line wraps). Click on the first line (the header) to cancel.

The suggestions listed normally replace a highlighted bad word. Sometimes they include other text, in that case the replaced text is also listed after a "<".

If a count is used that suggestion is used, without prompting. For example, "`1z=`" always takes the first suggestion.

If '**verbose**' is non-zero a score will be displayed with the suggestions to indicate the likeliness to the badly spelled word (the higher the score the more different).

When a word was replaced the redo command `."` will repeat the word replacement. This works like "`ciw`", the good word and `<Esc>`. This does NOT work for Thai and other languages without spaces between words.

`:spellr[epall]` Repeat the replacement done by `z=` for all matches with the replaced word in the current window.

In Insert mode, when the cursor is after a badly spelled word, you can use

**CTRL-X** s to find suggestions. This works like Insert mode completion. Use **CTRL-N** to use the next suggestion, **CTRL-P** to go back. `i_CTRL-X_s`

The **'spellsuggest'** option influences how the list of suggestions is generated and sorted. See **'spellsuggest'** .

The **'spellcapcheck'** option is used to check the first word of a sentence starts with a capital. This doesn't work for the first word in the file. When there is a line break right after a sentence the highlighting of the next line may be postponed. Use **CTRL-L** when needed. Also see `set-spc-auto` for how it can be set automatically when **'spelllang'** is set.

The **'spelloptions'** option has a few more flags that influence the way spell checking works. For example, "camel" splits CamelCased words so that each part of the word is spell-checked separately.

Vim counts the number of times a good word is encountered. This is used to sort the suggestions: words that have been seen before get a small bonus, words that have been seen often get a bigger bonus. The COMMON item in the affix file can be used to define common words, so that this mechanism also works in a new or short file `spell-COMMON` .

=====  
2. Remarks on spell checking spell-remarks

#### PERFORMANCE

Vim does on-the-fly spell checking. To make this work fast the word list is loaded in memory. Thus this uses a lot of memory (1 Mbyte or more). There might also be a noticeable delay when the word list is loaded, which happens when **'spell'** is set and when **'spelllang'** is set while **'spell'** was already set. To minimize the delay each word list is only loaded once, it is not deleted when **'spelllang'** is made empty or **'spell'** is reset. When **'encoding'** is set all the word lists are reloaded, thus you may notice a delay then too.

#### REGIONS

A word may be spelled differently in various regions. For example, English comes in (at least) these variants:

en	all regions
en_au	Australia
en_ca	Canada
en_gb	Great Britain
en_nz	New Zealand
en_us	USA

Words that are not used in one region but are used in another region are highlighted with SpellLocal `hl-SpellLocal` .

Always use lowercase letters for the language and region names.

When adding a word with `zg` or another command it's always added for all

regions. You can change that by manually editing the **'spellfile'**. See [spell-wordlist-format](#). Note that the regions as specified in the files in **'spellfile'** are only used when all entries in **'spelllang'** specify the same region (not counting files specified by their .spl name).

#### spell-german

Specific exception: For German these special regions are used:

de	all German words accepted
de_de	old and new spelling
de_19	old spelling
de_20	new spelling
de_at	Austria
de_ch	Switzerland

#### spell-russian

Specific exception: For Russian these special regions are used:

ru	all Russian words accepted
ru_ru	"IE" letter spelling
ru_yo	"YO" letter spelling

#### spell-yiddish

Yiddish requires using "utf-8" encoding, because of the special characters used. If you are using latin1 Vim will use transliterated (romanized) Yiddish instead. If you want to use transliterated Yiddish with utf-8 use "yi-tr".

In a table:

<b>'encoding'</b>	<b>'spelllang'</b>	
utf-8	yi	Yiddish
latin1	yi	transliterated Yiddish
utf-8	yi-tr	transliterated Yiddish

#### spell-cjk

Chinese, Japanese and other East Asian characters are normally marked as errors, because spell checking of these characters is not supported. If **'spelllang'** includes "cjk", these characters are not marked as errors. This is useful when editing text with spell checking while some Asian words are present.

## SPELL FILES

#### spell-load

Vim searches for spell files in the "spell" subdirectory of the directories in **'runtimepath'**. The name is: LL.EEE.spl, where:

LL	the language name
EEE	the value of <b>'encoding'</b>

The value for "LL" comes from **'spelllang'**, but excludes the region name.

Examples:

<b>'spelllang'</b>	LL
en_us	en
en-rare	en-rare
medical_ca	medical

Only the first file is loaded, the one that is first in **'runtimepath'**. If this succeeds then additionally files with the name LL.EEE.add.spl are loaded.

All the ones that are found are used.

If no spell file is found the `SpellFileMissing` autocommand event is triggered. This may trigger the `spellfile.vim` plugin to offer you downloading the spell file.

Additionally, the files related to the names in `'spellfile'` are loaded. These are the files that `zg` and `zw` add good and wrong words to.

Exceptions:

- Vim uses "latin1" when `'encoding'` is "iso-8859-15". The euro sign doesn't matter for spelling.
- When no spell file for `'encoding'` is found "ascii" is tried. This only works for languages where nearly all words are ASCII, such as English. It helps when `'encoding'` is not "latin1", such as iso-8859-2, and English text is being edited. For the ".add" files the same name as the found main spell file is used.

For example, with these values:

```
'runtimepath' is "~/vim,/usr/share/vim82,~/vim/after"
'encoding' is "iso-8859-2"
'spelllang' is "pl"
```

Vim will look for:

1. `~/vim/spell/pl.iso-8859-2.spl`
2. `/usr/share/vim82/spell/pl.iso-8859-2.spl`
3. `~/vim/spell/pl.iso-8859-2.add.spl`
4. `/usr/share/vim82/spell/pl.iso-8859-2.add.spl`
5. `~/vim/after/spell/pl.iso-8859-2.add.spl`

This assumes 1. is not found and 2. is found.

If `'encoding'` is "latin1" Vim will look for:

1. `~/vim/spell/pl.latin1.spl`
2. `/usr/share/vim82/spell/pl.latin1.spl`
3. `~/vim/after/spell/pl.latin1.spl`
4. `~/vim/spell/pl.ascii.spl`
5. `/usr/share/vim82/spell/pl.ascii.spl`
6. `~/vim/after/spell/pl.ascii.spl`

This assumes none of them are found (Polish doesn't make sense when leaving out the non-ASCII characters).

Spelling for EBCDIC is currently not supported.

A spell file might not be available in the current `'encoding'`. See `spell-mkspell` about how to create a spell file. Converting a spell file with "iconv" will NOT work!

**Note:** on VMS `"_{enc}.spl"` is changed to `"_{enc}.spl"` to avoid trouble with filenames.

[spell-sug-file](#) E781

If there is a file with exactly the same name as the ".spl" file but ending in

".sug", that file will be used for giving better suggestions. It isn't loaded before suggestions are made to reduce memory use.

E758 E759 E778 E779 E780 E782

When loading a spell file Vim checks that it is properly formatted. If you get an error the file may be truncated, modified or intended for another Vim version.

## SPELLFILE CLEANUP

spellfile-cleanup

The `zw` command turns existing entries in '`spellfile`' into comment lines. This avoids having to write a new file every time, but results in the file only getting longer, never shorter. To clean up the comment lines in all ".add" spell files do this:

```
:runtime spell/cleanadd.vim
```

This deletes all comment lines, except the ones that start with "###". Use "###" lines to add comments that you want to keep.

You can invoke this script as often as you like. A variable is provided to skip updating files that have been changed recently. Set it to the number of seconds that has passed since a file was changed before it will be cleaned. For example, to clean only files that were not changed in the last hour:

```
let g:spell_clean_limit = 60 * 60
```

The default is one second.

## WORDS

Vim uses a fixed method to recognize a word. This is independent of '`iskeyword`', so that it also works in help files and for languages that include characters like '-' in '`iskeyword`'. The word characters do depend on '`encoding`'.

The table with word characters is stored in the main .spl file. Therefore it matters what the current locale is when generating it! A .add.spl file does not contain a word table though.

For a word that starts with a digit the digit is ignored, unless the word as a whole is recognized. Thus if "3D" is a word and "D" is not then "3D" is recognized as a word, but if "3D" is not a word then only the "D" is marked as bad. Hex numbers in the form 0x12ab and 0X12AB are recognized.

## WORD COMBINATIONS

It is possible to spell-check words that include a space. This is used to recognize words that are invalid when used by themselves, e.g. for "et al.". It can also be used to recognize "the the" and highlight it.

The number of spaces is irrelevant. In most cases a line break may also appear. However, this makes it difficult to find out where to start checking for spelling mistakes. When you make a change to one line and only that line

is redrawn Vim won't look in the previous line, thus when "et" is at the end of the previous line "al." will be flagged as an error. And when you type "the<CR>the" the highlighting doesn't appear until the first line is redrawn. Use `CTRL-L` to redraw right away. "[s" will also stop at a word combination with a line break.

When encountering a line break Vim skips characters such as '\*', '>' and "'", so that comments in C, shell and Vim code can be spell checked.

## SYNTAX HIGHLIGHTING

[spell-syntax](#)

Files that use syntax highlighting can specify where spell checking should be done:

1. everywhere default
2. in specific items use "contains=@Spell"
3. everywhere but specific items use "contains=@NoSpell"

For the second method adding the @NoSpell cluster will disable spell checking again. This can be used, for example, to add @Spell to the comments of a program, and add @NoSpell for items that shouldn't be checked. Also see [:syn-spell](#) for text that is not in a syntax item.

## VIM SCRIPTS

If you want to write a Vim script that does something with spelling, you may find these functions useful:

spellbadword()	find badly spelled word at the cursor
spellsuggest()	get list of spelling suggestions
soundfold()	get the sound-a-like version of a word

## SETTING '[spellcapcheck](#)' AUTOMATICALLY

[set-spc-auto](#)

After the '[spelllang](#)' option has been set successfully, Vim will source the files "spell/LANG.vim" in '[runtimepath](#)'. "LANG" is the value of '[spelllang](#)' up to the first comma, dot or underscore. This can be used to set options specifically for the language, especially '[spellcapcheck](#)'.

The distribution includes a few of these files. Use this command to see what they do:

```
:next $VIMRUNTIME/spell/*.vim
```

**Note** that the default scripts don't set '[spellcapcheck](#)' if it was changed from the default value. This assumes the user prefers another value then.

## DOUBLE SCORING

[spell-double-scoring](#)

The '[spellsuggest](#)' option can be used to select "double" scoring. This mechanism is based on the principle that there are two kinds of spelling

mistakes:

1. You know how to spell the word, but mistype something. This results in a small editing distance (character swapped/omitted/inserted) and possibly a word that sounds completely different.
2. You don't know how to spell the word and type something that sounds right. The edit distance can be big but the word is similar after sound-folding.

Since scores for these two mistakes will be very different we use a list for each and mix them.

The sound-folding is slow and people that know the language won't make the second kind of mistakes. Therefore **'spellsuggest'** can be set to select the preferred method for scoring the suggestions.

---

### 3. Generating a spell file

**spell-mkspell**

Vim uses a binary file format for spelling. This greatly speeds up loading the word list and keeps it small.

**.aff .dic Myspell**

You can create a Vim spell file from the .aff and .dic files that Myspell uses. Myspell is used by OpenOffice.org and Mozilla. The OpenOffice .oxt files are zip files which contain the .aff and .dic files. You should be able to find them here:

<http://extensions.services.openoffice.org/dictionary>

The older, OpenOffice 2 files may be used if this doesn't work:

<http://wiki.services.openoffice.org/wiki/Dictionaryes>

You can also use a plain word list. The results are the same, the choice depends on what word lists you can find.

If you install Aap (from [www.a-a-p.org](http://www.a-a-p.org)) you can use the recipes in the runtime/spell/??/ directories. Aap will take care of downloading the files, apply patches needed for Vim and build the .spl file.

Make sure your current locale is set properly, otherwise Vim doesn't know what characters are upper/lower case letters. If the locale isn't available (e.g., when using an MS-Windows codepage on Unix) add tables to the .aff file

**spell-affix-chars**. If the .aff file doesn't define a table then the word table of the currently active spelling is used. If spelling is not active then Vim will try to guess.

**:mksp :mkspell**

**:mksp[ell][!] [-ascii] {outname} {iname} ...**

Generate a Vim spell file from word lists. Example:

**:mkspell /tmp/nl nl\_NL.words**

**E751**

When {outname} ends in ".spl" it is used as the output file name. Otherwise it should be a language name, such as "en", without the region name. The file written will be "{outname}.{encoding}.spl", where {encoding} is the value of the **'encoding'** option.

When the output file already exists [!] must be used to overwrite it.

When the [-ascii] argument is present, words with non-ascii characters are skipped. The resulting file ends in "ascii.spl".

The input can be the Myspell format files {inname}.aff and {inname}.dic. If {inname}.aff does not exist then {inname} is used as the file name of a plain word list.

Multiple {inname} arguments can be given to combine regions into one Vim spell file. Example:

```
:mkspell ~/.vim/spell/en /tmp/en_US /tmp/en_CA /tmp/en_AU
```

This combines the English word lists for US, CA and AU into one en.spl file.

Up to eight regions can be combined. E754 E755  
The REP and SAL items of the first .aff file where they appear are used. spell-REP spell-SAL  
E845

This command uses a lot of memory, required to find the optimal word tree (Polish, Italian and Hungarian require several hundred Mbyte). The final result will be much smaller, because compression is used. To avoid running out of memory compression will be done now and then. This can be tuned with the 'mkspellmem' option.

After the spell file was written and it was being used in a buffer it will be reloaded automatically.

```
:mksp[ell] [-ascii] {name}.{enc}.add
```

Like ":mkspell" above, using {name}.{enc}.add as the input file and producing an output file in the same directory that has ".spl" appended.

```
:mksp[ell] [-ascii] {name}
```

Like ":mkspell" above, using {name} as the input file and producing an output file in the same directory that has ".{enc}.spl" appended.

Vim will report the number of duplicate words. This might be a mistake in the list of words. But sometimes it is used to have different prefixes and suffixes for the same basic word to avoid them combining (e.g. Czech uses this). If you want Vim to report all duplicate words set the 'verbose' option.

Since you might want to change a Myspell word list for use with Vim the following procedure is recommended:

1. Obtain the xx\_YY.aff and xx\_YY.dic files from Myspell.
2. Make a copy of these files to xx\_YY.orig.aff and xx\_YY.orig.dic.
3. Change the xx\_YY.aff and xx\_YY.dic files to remove bad words, add missing

words, define word characters with FOL/LOW/UPP, etc. The distributed "\*.diff" files can be used.

4. Start Vim with the right locale and use `:mkspell` to generate the Vim spell file.
5. Try out the spell file with `":set spell spelllang=xx"` if you wrote it in a spell directory in `'runtimepath'`, or `":set spelllang=xx.enc.spl"` if you wrote it somewhere else.

When the Myspell files are updated you can merge the differences:

1. Obtain the new Myspell files as `xx_YY.new.aff` and `xx_UU.new.dic`.
2. Use Vimdiff to see what changed:  
`vimdiff xx_YY.orig.dic xx_YY.new.dic`
3. Take over the changes you like in `xx_YY.dic`.  
You may also need to change `xx_YY.aff`.
4. Rename `xx_YY.new.dic` to `xx_YY.orig.dic` and `xx_YY.new.aff` to `xx_YY.orig.aff`.

## SPELL FILE VERSIONS

E770 E771 E772

Spell checking is a relatively new feature in Vim, thus it's possible that the .spl file format will be changed to support more languages. Vim will check the validity of the spell file and report anything wrong.

**E771: Old spell file, needs to be updated**

This spell file is older than your Vim. You need to update the .spl file.

**E772: Spell file is for newer version of Vim**

This means the spell file was made for a later version of Vim. You need to update Vim.

**E770: Unsupported section in spell file**

This means the spell file was made for a later version of Vim and contains a section that is required for the spell file to work. In this case it's probably a good idea to upgrade your Vim.

## SPELL FILE DUMP

If for some reason you want to check what words are supported by the currently used spelling files, use this command:

<code>:spellld[ump]</code>	<code>:spellldump</code> <code>:spellld</code> Open a new window and fill it with all currently valid words. Compound words are not included. <b>Note:</b> For some languages the result may be enormous, causing Vim to run out of memory.
<code>:spellld[ump]!</code>	Like <code>":spellldump"</code> and include the word count. This is the number of times the word was found while updating the screen. Words that are in COMMON items get a starting count of 10.

The format of the word list is used `spell-wordlist-format`. You should be able to read it with `":mkspell"` to generate one .spl file that includes all

the words.

When all entries to **'spelllang'** use the same regions or no regions at all then the region information is included in the dumped words. Otherwise only words for the current region are included and no `"/regions"` line is generated.

Comment lines with the name of the `.spl` file are used as a header above the words that were generated from that `.spl` file.

## **SPELL FILE MISSING** `spell-SpellFileMissing` `spellfile.vim`

If the spell file for the language you are using is not available, you will get an error message. But if the `"spellfile.vim"` plugin is active it will offer you to download the spell file. Just follow the instructions, it will ask you where to write the file (there must be a writable directory in **'runtimepath'** for this).

The plugin has a default place where to look for spell files, on the Vim ftp server. The protocol used is SSL (`https://`) for security. If you want to use another location or another protocol, set the `g:spellfile_URL` variable to the directory that holds the spell files. You can use `http://` or `ftp://`, but you are taking a security risk then. The `netrw` plugin is used for getting the file, look there for the specific syntax of the URL. Example:

```
let g:spellfile_URL = 'https://ftp.nluug.nl/vim/runtime/spell'
```

You may need to escape special characters.

The plugin will only ask about downloading a language once. If you want to try again anyway restart Vim, or set `g:spellfile_URL` to another value (e.g., prepend a space).

To avoid using the `"spellfile.vim"` plugin do this in your `vimrc` file:

```
let loaded_spellfile_plugin = 1
```

Instead of using the plugin you can define a `SpellFileMissing` autocommand to handle the missing file yourself. You can use it like this:

```
:au SpellFileMissing * call Download_spell_file(expand('<amatch>'))
```

Thus the `<amatch>` item contains the name of the language. Another important value is **'encoding'**, since every encoding has its own spell file. With two exceptions:

- For ISO-8859-15 (latin9) the name `"latin1"` is used (the encodings only differ in characters not used in dictionary words).
- The name `"ascii"` may also be used for some languages where the words use only ASCII letters for most of the words.

The default `"spellfile.vim"` plugin uses this autocommand, if you define your autocommand afterwards you may want to use `":au! SpellFileMissing"` to overrule it. If you define your autocommand before the plugin is loaded it will notice this and not do anything.

E797

**Note** that the `SpellFileMissing` autocommand must not change or destroy the

buffer the user was editing.

---

#### 4. Spell file format

spell-file-format

This is the format of the files that are used by the person who creates and maintains a word list.

**Note** that we avoid the word "dictionary" here. That is because the goal of spell checking differs from writing a dictionary (as in the book). For spelling we need a list of words that are OK, thus should not be highlighted. Person and company names will not appear in a dictionary, but do appear in a word list. And some old words are rarely used while they are common misspellings. These do appear in a dictionary but not in a word list.

There are two formats: A straight list of words and a list using affix compression. The files with affix compression are used by Myspell (Mozilla and OpenOffice.org). This requires two files, one with .aff and one with .dic extension.

#### **FORMAT OF STRAIGHT WORD LIST**

spell-wordlist-format

The words must appear one per line. That is all that is required.

Additionally the following items are recognized:

- Empty and blank lines are ignored.

`# comment`

- Lines starting with a # are ignored (comment lines).

`/encoding=utf-8`

- A line starting with "/encoding=", before any word, specifies the encoding of the file. After the second '=' comes an encoding name. This tells Vim to setup conversion from the specified encoding to '**encoding**'. Thus you can use one word list for several target encodings.

`/regions=usca`

- A line starting with "/regions=" specifies the region names that are supported. Each region name must be two ASCII letters. The first one is region 1. Thus "/regions=usca" has region 1 "us" and region 2 "ca". In an addition word list the region names should be equal to the main word list!

- Other lines starting with '/' are reserved for future use. The ones that are not recognized are ignored. You do get a warning message, so that you know something won't work.

- A "/" may follow the word with the following items:

= Case must match exactly.

? Rare word.

! Bad (wrong) word.

1 to 9 A region in which the word is valid. If no regions are

specified the word is valid in all regions.

Example:

```
This is an example word list comment
/encoding=latin1 encoding of the file
/regions=uscagb regions "us", "ca" and "gb"
example word for all regions
blah/12 word for regions "us" and "ca"
vim/! bad word
Campbell/?3 rare word in region 3 "gb"
's mornings/= keep-case word
```

**Note** that when "/=" is used the same word with all upper-case letters is not accepted. This is different from a word with mixed case that is automatically marked as keep-case, those words may appear in all upper-case letters.

### FORMAT WITH .AFF AND .DIC FILES

[aff-dic-format](#)

There are two files: the basic word list and an affix file. The affix file specifies settings for the language and can contain affixes. The affixes are used to modify the basic words to get the full word list. This significantly reduces the number of words, especially for a language like Polish. This is called affix compression.

The basic word list and the affix file are combined with the ":mkspell" command and results in a binary spell file. All the preprocessing has been done, thus this file loads fast. The binary spell file format is described in the source code (src/spell.c). But only developers need to know about it.

The preprocessing also allows us to take the Myspell language files and modify them before the Vim word list is made. The tools for this can be found in the "src/spell" directory.

The format for the affix and word list files is based on what Myspell uses (the spell checker of Mozilla and OpenOffice.org). A description can be found here:

<http://linguocomponent.openoffice.org/affix.readme>

**Note** that affixes are case sensitive, this isn't obvious from the description.

Vim supports quite a few extras. They are described below [spell-affix-vim](#). Attempts have been made to keep this compatible with other spell checkers, so that the same files can often be used. One other project that offers more than Myspell is Hunspell (<http://hunspell.sf.net>).

### WORD LIST FORMAT

[spell-dic-format](#)

A short example, with line numbers:

```
1 1234
2 aan
3 Als
```

```

4 Etten-Leur
5 et al.
6 's-Gravenhage
7 's-Gravenhaags
8 # word that differs between regions
9 kado/1
10 cadeau/2
11 TCP,IP
12 /the S affix may add a 's'
13 bedel/S

```

The first line contains the number of words. Vim ignores it, but you do get an error message if it's not there. [E760](#)

What follows is one word per line. White space at the end of the line is ignored, all other white space matters. The encoding is specified in the affix file [spell-SET](#) .

Comment lines start with '#' or '/'. See the example lines 8 and 12. [Note](#) that putting a comment after a word is NOT allowed:

```

 someword # comment that causes an error!

```

After the word there is an optional slash and flags. Most of these flags are letters that indicate the affixes that can be used with this word. These are specified with SFX and PFX lines in the .aff file, see [spell-SFX](#) and [spell-PFX](#) . Vim allows using other flag types with the FLAG item in the affix file [spell-FLAG](#) .

When the word only has lower-case letters it will also match with the word starting with an upper-case letter.

When the word includes an upper-case letter, this means the upper-case letter is required at this position. The same word with a lower-case letter at this position will not match. When some of the other letters are upper-case it will not match either.

The word with all upper-case characters will always be OK,

word list	matches	does not match
als	als AlS ALS	ALs ALs aLs aLS
Als	Als ALS	als ALs ALs aLs aLS
ALS	ALS	als Als ALS ALs aLs aLS
ALS	ALS ALS	als Als ALS aLs aLS

The KEEPCASE affix ID can be used to specifically match a word with identical case only, see below [spell-KEEPCASE](#) .

[Note:](#) in line 5 to 7 non-word characters are used. You can include any character in a word. When checking the text a word still only matches when it appears with a non-word character before and after it. For Myspell a word starting with a non-word character probably won't work.

In line 12 the word "TCP/IP" is defined. Since the slash has a special

meaning the comma is used instead. This is defined with the SLASH item in the affix file, see `spell-SLASH`. Note that without this SLASH item the word will be "TCP,IP".

## AFFIX FILE FORMAT

`spell-aff-format` `spell-affix-vim`

`spell-affix-comment`

Comment lines in the .aff file start with a '#':

```
comment line
```

Items with a fixed number of arguments can be followed by a comment. But only if none of the arguments can contain white space. The comment must start with a '#' character. Example:

```
KEEPCASE = # fix case for words with this flag
```

## ENCODING

`spell-SET`

The affix file can be in any encoding that is supported by "iconv". However, in some cases the current locale should also be set properly at the time `:mkspell` is invoked. Adding FOL/LOW/UPP lines removes this requirement `spell-FOL`.

The encoding should be specified before anything where the encoding matters. The encoding applies both to the affix file and the dictionary file. It is done with a SET line:

```
SET utf-8
```

The encoding can be different from the value of the '`encoding`' option at the time `:mkspell` is used. Vim will then convert everything to '`encoding`' and generate a spell file for '`encoding`'. If some of the used characters do not fit in '`encoding`' you will get an error message.

`spell-affix-mbyte`

When using a multibyte encoding it's possible to use more different affix flags. But Myspell doesn't support that, thus you may not want to use it anyway. For compatibility use an 8-bit encoding.

## INFORMATION

These entries in the affix file can be used to add information to the spell file. There are no restrictions on the format, but they should be in the right encoding.

`spell-NAME` `spell-VERSION` `spell-HOME`  
`spell-AUTHOR` `spell-EMAIL` `spell-COPYRIGHT`

```
NAME Name of the language
VERSION 1.0.1 with fixes
HOME <URL>
AUTHOR John Doe
```

EMAIL john AT Doe DOT net  
COPYRIGHT LGPL

These fields are put in the .spl file as-is. The `:spellinfo` command can be used to view the info.

`:spelli[nfo]` `:spellinfo` `:spelli`  
Display the information for the spell file(s) used for the current buffer.

## CHARACTER TABLES

`spell-affix-chars`  
When using an 8-bit encoding the affix file should define what characters are word characters. This is because the system where `":mkspell"` is used may not support a locale with this encoding and `isalpha()` won't work. For example when using `"cp1250"` on Unix.

`E761` `E762` `spell-FOL`  
`spell-LOW` `spell-UPP`  
Three lines in the affix file are needed. Simplistic example:

```
FOL áěň
LOW áěň
UPP ÁĚŇ
```

All three lines must have exactly the same number of characters.

The "FOL" line specifies the case-folded characters. These are used to compare words while ignoring case. For most encodings this is identical to the lower case line.

The "LOW" line specifies the characters in lower-case. Mostly it's equal to the "FOL" line.

The "UPP" line specifies the characters with upper-case. That is, a character is upper-case where it's different from the character at the same position in "FOL".

An exception is made for the German sharp s ß. The upper-case version is "SS". In the FOL/LOW/UPP lines it should be included, so that it's recognized as a word character, but use the ß character in all three.

ASCII characters should be omitted, Vim always handles these in the same way. When the encoding is UTF-8 no word characters need to be specified.

`E763`  
Vim allows you to use spell checking for several languages in the same file. You can list them in the `'spelllang'` option. As a consequence all spell files for the same encoding must use the same word characters, otherwise they can't be combined without errors.

If you get an E763 warning that the word tables differ you need to update your ".spl" spell files. If you downloaded the files, get the latest version of all spell files you use. If you are only using one, e.g., German, then also

download the recent English spell files. Otherwise generate the .spl file again with `:mkspell`. If you still get errors check the FOL, LOW and UPP lines in the used .aff files.

The XX.ascii.spl spell file generated with the "-ascii" argument will not contain the table with characters, so that it can be combine with spell files for any encoding. The .add.spl files also do not contain the table.

## MID-WORD CHARACTERS

spell-midword

Some characters are only to be considered word characters if they are used in between two ordinary word characters. An example is the single quote: It is often used to put text in quotes, thus it can't be recognized as a word character, but when it appears in between word characters it must be part of the word. This is needed to detect a spelling error such as they'are. That should be they're, but since "they" and "are" are words themselves that would go unnoticed.

These characters are defined with MIDWORD in the .aff file. Example:

```
MIDWORD '-
```

## FLAG TYPES

spell-FLAG

Flags are used to specify the affixes that can be used with a word and for other properties of the word. Normally single-character flags are used. This limits the number of possible flags, especially for 8-bit encodings. The FLAG item can be used if more affixes are to be used. Possible values:

FLAG long	use two-character flags
FLAG num	use numbers, from 1 up to 65000
FLAG caplong	use one-character flags without A-Z and two-character flags that start with A-Z

With "FLAG num" the numbers in a list of affixes need to be separated with a comma: "234,2143,1435". This method is inefficient, but useful if the file is generated with a program.

When using "caplong" the two-character flags all start with a capital: "Aa", "B1", "BB", etc. This is useful to use one-character flags for the most common items and two-character flags for uncommon items.

**Note:** When using utf-8 only characters up to 65000 may be used for flags.

**Note:** even when using "num" or "long" the number of flags available to compounding and prefixes is limited to about 250.

## AFFIXES

spell-PFX spell-SFX

The usual PFX (prefix) and SFX (suffix) lines are supported (see the Myspell documentation or the Aspell manual:

<http://aspell.net/man-html/Affix-Compression.html>).

Summary:

```
SFX L Y 2
SFX L 0 re [^x]
SFX L 0 ro x
```

The first line is a header and has four fields:

```
SFX {flag} {combine} {count}
```

**{flag}** The name used for the suffix. Mostly it's a single letter, but other characters can be used, see [spell-FLAG](#) .

**{combine}** Can be 'Y' or 'N'. When 'Y' then the word plus suffix can also have a prefix. When 'N' then a prefix is not allowed.

**{count}** The number of lines following. If this is wrong you will get an error message.

For PFX the fields are exactly the same.

The basic format for the following lines is:

```
SFX {flag} {strip} {add} {condition} {extra}
```

**{flag}** Must be the same as the **{flag}** used in the first line.

**{strip}** Characters removed from the basic word. There is no check if the characters are actually there, only the length is used (in bytes). This better match the **{condition}**, otherwise strange things may happen. If the **{strip}** length is equal to or longer than the basic word the suffix won't be used. When **{strip}** is 0 (zero) then nothing is stripped.

**{add}** Characters added to the basic word, after removing **{strip}**. Optionally there is a '/' followed by flags. The flags apply to the word plus affix. See [spell-affix-flags](#)

**{condition}** A simplistic pattern. Only when this matches with a basic word will the suffix be used for that word. This is normally for using one suffix letter with different **{add}** and **{strip}** fields for words with different endings.

When **{condition}** is a . (dot) there is no condition.

The pattern may contain:

- Literal characters.
- A set of characters in []. **[abc]** matches a, b and c. A dash is allowed for a range **[a-c]**, but this is Vim-specific.
- A set of characters that starts with a ^, meaning the complement of the specified characters. **[^abc]** matches any character but a, b and c.

**{extra}** Optional extra text:

```
comment Comment is ignored
- Hunspell uses this, ignored
```

For PFX the fields are the same, but the `{strip}`, `{add}` and `{condition}` apply to the start of the word.

**Note:** Myspell ignores any extra text after the relevant info. Vim requires this text to start with a "#" so that mistakes don't go unnoticed. Example:

```
SFX F 0 in [^i]n # Spion > Spionin
SFX F 0 nen in # Bauerin > Bauerinnen
```

However, to avoid lots of errors in affix files written for Myspell, you can add the IGNOREEXTRA flag.

Apparently Myspell allows an affix name to appear more than once. Since this might also be a mistake, Vim checks for an extra "S". The affix files for Myspell that use this feature apparently have this flag. Example:

```
SFX a Y 1 S
SFX a 0 an .

SFX a Y 2 S
SFX a 0 en .
SFX a 0 on .
```

## AFFIX FLAGS

## spell-affix-flags

This is a feature that comes from Hunspell: The affix may specify flags. This works similar to flags specified on a basic word. The flags apply to the basic word plus the affix (but there are restrictions). Example:

```
SFX S Y 1
SFX S 0 s .

SFX A Y 1
SFX A 0 able/S .
```

When the dictionary file contains "drink/AS" then these words are possible:

```
drink
drinks uses S suffix
drinkable uses A suffix
drinkables uses A suffix and then S suffix
```

Generally the flags of the suffix are added to the flags of the basic word, both are used for the word plus suffix. But the flags of the basic word are only used once for affixes, except that both one prefix and one suffix can be used when both support combining.

Specifically, the affix flags can be used for:

- Suffixes on suffixes, as in the example above. This works once, thus you can have two suffixes on a word (plus one prefix).
- Making the word with the affix rare, by using the `spell-RARE` flag.
- Exclude the word with the affix from compounding, by using the

`spell-COMPOUNDFORBIDFLAG` flag.

- Allow the word with the affix to be part of a compound word on the side of the affix with the `spell-COMPOUNDPERMITFLAG` .
- Use the `NEEDCOMPOUND` flag: word plus affix can only be used as part of a compound word. `spell-NEEDCOMPOUND`
- Compound flags: word plus affix can be part of a compound word at the end, middle, start, etc. The flags are combined with the flags of the basic word. `spell-compound`
- `NEEDAFFIX`: another affix is needed to make a valid word.
- `CIRCUMFIX`, as explained just below.

## **IGNOREEXTRA**

`spell-IGNOREEXTRA`

Normally Vim gives an error for an extra field that does not start with '#'. This avoids errors going unnoticed. However, some files created for Myspell or Hunspell may contain many entries with an extra field. Use the `IGNOREEXTRA` flag to avoid lots of errors.

## **CIRCUMFIX**

`spell-CIRCUMFIX`

The `CIRCUMFIX` flag means a prefix and suffix must be added at the same time. If a prefix has the `CIRCUMFIX` flag then only suffixes with the `CIRCUMFIX` flag can be added, and the other way around.

An alternative is to only specify the suffix, and give that suffix two flags: the required prefix and the `NEEDAFFIX` flag. `spell-NEEDAFFIX`

## **PFXPOSTPONE**

`spell-PFXPOSTPONE`

When an affix file has very many prefixes that apply to many words it's not possible to build the whole word list in memory. This applies to Hebrew (a list with all words is over a Gbyte). In that case applying prefixes must be postponed. This makes spell checking slower. It is indicated by this keyword in the `.aff` file:

`PFXPOSTPONE`

Only prefixes without a chop string and without flags can be postponed. Prefixes with a chop string or with flags will still be included in the word list. An exception if the chop string is one character and equal to the last character of the added string, but in lower case. Thus when the chop string is used to allow the following word to start with an upper case letter.

## **WORDS WITH A SLASH**

`spell-SLASH`

The slash is used in the `.dic` file to separate the basic word from the affix letters and other flags. Unfortunately, this means you cannot use a slash in a word. Thus "TCP/IP" is not a word but "TCP" with the flags "IP". To include a slash in the word put a backslash before it: "TCP\IP". In the rare case you want to use a backslash inside a word you need to use two backslashes. Any other use of the backslash is reserved for future expansion.

## KEEP-CASE WORDS

spell-KEEPCASE

In the affix file a KEEPCASE line can be used to define the affix name used for keep-case words. Example:

```
KEEPCASE =
```

This flag is not supported by Myspell. It has the meaning that case matters. This can be used if the word does not have the first letter in upper case at the start of a sentence. Example:

word list	matches	does not match
's morgens/=	's morgens	'S morgens 's Morgens 'S MORGENS
's Morgens	's Morgens 'S MORGENS	'S morgens 's morgens

The flag can also be used to avoid that the word matches when it is in all upper-case letters.

## RARE WORDS

spell-RARE

In the affix file a RARE line can be used to define the affix name used for rare words. Example:

```
RARE ?
```

Rare words are highlighted differently from bad words. This is to be used for words that are correct for the language, but are hardly ever used and could be a typing mistake anyway. When the same word is found as good it won't be highlighted as rare.

This flag can also be used on an affix, so that a basic word is not rare but the basic word plus affix is rare [spell-affix-flags](#). However, if the word also appears as a good word in another way (e.g., in another region) it won't be marked as rare.

## BAD WORDS

spell-BAD

In the affix file a BAD line can be used to define the affix name used for bad words. Example:

```
BAD !
```

This can be used to exclude words that would otherwise be good. For example "the the" in the .dic file:

```
the the/!
```

Once a word has been marked as bad it won't be undone by encountering the same word as good.

The flag also applies to the word with affixes, thus this can be used to mark a whole bunch of related words as bad.

`spell-FORBIDDENWORD`

FORBIDDENWORD can be used just like BAD. For compatibility with Hunspell.

`spell-NEEDAFFIX`

The NEEDAFFIX flag is used to require that a word is used with an affix. The word itself is not a good word (unless there is an empty affix). Example:

`NEEDAFFIX +`

## COMPOUND WORDS

`spell-compound`

A compound word is a longer word made by concatenating words that appear in the .dic file. To specify which words may be concatenated a character is used. This character is put in the list of affixes after the word. We will call this character a flag here. Obviously these flags must be different from any affix IDs used.

`spell-COMPOUNDFLAG`

The Myspell compatible method uses one flag, specified with COMPOUNDFLAG. All words with this flag combine in any order. This means there is no control over which word comes first. Example:

`COMPOUNDFLAG c`

`spell-COMPOUNDRULE`

A more advanced method to specify how compound words can be formed uses multiple items with multiple flags. This is not compatible with Myspell 3.0. Let's start with an example:

`COMPOUNDRULE c+`

`COMPOUNDRULE se`

The first line defines that words with the "c" flag can be concatenated in any order. The second line defines compound words that are made of one word with the "s" flag and one word with the "e" flag. With this dictionary:

`bork/c`  
`onion/s`  
`soup/e`

You can make these words:

`bork`  
`borkbork`  
`borkborkbork`  
`(etc.)`  
`onion`  
`soup`  
`onionsoup`

The COMPOUNDRULE item may appear multiple times. The argument is made out of one or more groups, where each group can be:

one flag e.g., c  
alternate flags inside [] e.g., [abc]

Optionally this may be followed by:

*	the group appears zero or more times, e.g., sm*e
+	the group appears one or more times, e.g., c+
?	the group appears zero times or once, e.g., x?

This is similar to the regexp pattern syntax (but not the same!). A few examples with the sequence of word flags they require:

COMPOUNDRULE x+	x xx xxx etc.
COMPOUNDRULE yz	yz
COMPOUNDRULE x+z	xz xxz xxxz etc.
COMPOUNDRULE yx+	yx yxx yxxx etc.
COMPOUNDRULE xy?z	xz xyz
COMPOUNDRULE [abc]z	az bz cz
COMPOUNDRULE [abc]+z	az aaz abaz bz baz bcbz cz caz cbaz etc.
COMPOUNDRULE a[xyz]+	ax axx axyz ay ayx ayzz az azy azxy etc.
COMPOUNDRULE sm*e	se sme smme smmme etc.
COMPOUNDRULE s[xyz]*e	se sxe sxye sxyxe sye syze sze szye szyxe etc.

A specific example: Allow a compound to be made of two words and a dash:

In the .aff file:

```
COMPOUNDRULE sde
NEEDAFFIX x
COMPOUNDWORDMAX 3
COMPOUNDMIN 1
```

In the .dic file:

```
start/s
end/e
-/xd
```

This allows for the word "start-end", but not "startend".

An additional implied rule is that, without further flags, a word with a prefix cannot be compounded after another word, and a word with a suffix cannot be compounded with a following word. Thus the affix cannot appear on the inside of a compound word. This can be changed with the `spell-COMPOUNDPERMITFLAG`.

`spell-NEEDCOMPOUND`

The NEEDCOMPOUND flag is used to require that a word is used as part of a compound word. The word itself is not a good word. Example:

```
NEEDCOMPOUND &
```

`spell-ONLYINCOMPOUND`

The ONLYINCOMPOUND does exactly the same as NEEDCOMPOUND. Supported for compatibility with Hunspell.

`spell-COMPOUNDMIN`

The minimal character length of a word used for compounding is specified with COMPOUNDMIN. Example:

```
COMPOUNDMIN 5
```

When omitted there is no minimal length. Obviously you could just leave out

the compound flag from short words instead, this feature is present for compatibility with Myspell.

#### spell-COMPOUNDWORDMAX

The maximum number of words that can be concatenated into a compound word is specified with COMPOUNDWORDMAX. Example:

```
COMPOUNDWORDMAX 3
```

When omitted there is no maximum. It applies to all compound words.

To set a limit for words with specific flags make sure the items in COMPOUNDRULE where they appear don't allow too many words.

#### spell-COMPOUNDSYLMAX

The maximum number of syllables that a compound word may contain is specified with COMPOUNDSYLMAX. Example:

```
COMPOUNDSYLMAX 6
```

This has no effect if there is no SYLLABLE item. Without COMPOUNDSYLMAX there is no limit on the number of syllables.

If both COMPOUNDWORDMAX and COMPOUNDSYLMAX are defined, a compound word is accepted if it fits one of the criteria, thus is either made from up to COMPOUNDWORDMAX words or contains up to COMPOUNDSYLMAX syllables.

#### spell-COMPOUNDFORBIDFLAG

The COMPOUNDFORBIDFLAG specifies a flag that can be used on an affix. It means that the word plus affix cannot be used in a compound word. Example:

affix file:

```
COMPOUNDFLAG c
COMPOUNDFORBIDFLAG x
SFX a Y 2
SFX a 0 s .
SFX a 0 ize/x .
```

dictionary:

```
word/c
util/ac
```

This allows for "wordutil" and "wordutils" but not "wordutilize".

**Note:** this doesn't work for postponed prefixes yet.

#### spell-COMPOUNDPERMITFLAG

The COMPOUNDPERMITFLAG specifies a flag that can be used on an affix. It means that the word plus affix can also be used in a compound word in a way where the affix ends up halfway the word. Without this flag that is not allowed.

**Note:** this doesn't work for postponed prefixes yet.

#### spell-COMPOUNDROOT

The COMPOUNDROOT flag is used for words in the dictionary that are already a compound. This means it counts for two words when checking the compounding rules. Can also be used for an affix to count the affix as a compounding word.

### spell-CHECKCOMPOUNDPATTERN

CHECKCOMPOUNDPATTERN is used to define patterns that, when matching at the position where two words are compounded together forbids the compound. For example:

```
CHECKCOMPOUNDPATTERN o e
```

This forbids compounding if the first word ends in "o" and the second word starts with "e".

The arguments must be plain text, no patterns are actually supported, despite the item name. Case is always ignored.

The Hunspell feature to use three arguments and flags is not supported.

### spell-NOCOMPOUNDSUGS

This item indicates that using compounding to make suggestions is not a good idea. Use this when compounding is used with very short or one-character words. E.g. to make numbers out of digits. Without this flag creating suggestions would spend most time trying all kind of weird compound words.

```
NOCOMPOUNDSUGS
```

### spell-SYLLABLE

The SYLLABLE item defines characters or character sequences that are used to count the number of syllables in a word. Example:

```
SYLLABLE aáeéííóóóöüüüÿ/aa/au/ea/ee/ei/ie/oa/oe/oo/ou/uu/ui
```

Before the first slash is the set of characters that are counted for one syllable, also when repeated and mixed, until the next character that is not in this set. After the slash come sequences of characters that are counted for one syllable. These are preferred over using characters from the set. With the example "ideeen" has three syllables, counted by "i", "ee" and "e".

Only case-folded letters need to be included.

Another way to restrict compounding was mentioned above: Adding the `spell-COMPOUNDFORBIDFLAG` flag to an affix causes all words that are made with that affix to not be used for compounding.

## UNLIMITED COMPOUNDING

### spell-NOBREAK

For some languages, such as Thai, there is no space in between words. This looks like all words are compounded. To specify this use the NOBREAK item in the affix file, without arguments:

```
NOBREAK
```

Vim will try to figure out where one word ends and a next starts. When there are spelling mistakes this may not be quite right.

### spell-COMMON

Common words can be specified with the COMMON item. This will give better suggestions when editing a short file. Example:

```
COMMON the of to and a in is it you that he she was for on are
```

The words must be separated by white space, up to 25 per line.  
When multiple regions are specified in a ":mkspell" command the common words for all regions are combined and used for all regions.

```
spell-NOSPLITSUGS
```

This item indicates that splitting a word to make suggestions is not a good idea. Split-word suggestions will appear only when there are few similar words.

```
NOSPLITSUGS
```

```
spell-NOSUGGEST
```

The flag specified with NOSUGGEST can be used for words that will not be suggested. Can be used for obscene words.

```
NOSUGGEST %
```

## REPLACEMENTS

```
spell-REP
```

In the affix file REP items can be used to define common mistakes. This is used to make spelling suggestions. The items define the "from" text and the "to" replacement. Example:

```
REP 4
REP f ph
REP ph f
REP k ch
REP ch k
```

The first line specifies the number of REP lines following. Vim ignores the number, but it must be there (for compatibility with Myspell).

Don't include simple one-character replacements or swaps. Vim will try these anyway. You can include whole words if you want to, but you might want to use the "file:" item in '**spellsuggest**' instead.

You can include a space by using an underscore:

```
REP the_the the
```

## SIMILAR CHARACTERS

```
spell-MAP E783
```

In the affix file MAP items can be used to define letters that are very much alike. This is mostly used for a letter with different accents. This is used to prefer suggestions with these letters substituted. Example:

```
MAP 2
MAP eéëêè
MAP uüùúû
```

The first line specifies the number of MAP lines following. Vim ignores the number, but the line must be there.

Each letter must appear in only one of the MAP items. It's a bit more efficient if the first letter is ASCII or at least one without accents.

## **.SUG FILE**

spell-NOSUGFILE

When soundfolding is specified in the affix file then ":mkspell" will normally produce a .sug file next to the .spl file. This file is used to find suggestions by their sound-a-like form quickly. At the cost of a lot of memory (the amount depends on the number of words, :mkspell will display an estimate when it's done).

To avoid producing a .sug file use this item in the affix file:

NOSUGFILE

Users can simply omit the .sug file if they don't want to use it.

## **SOUND-A-LIKE**

spell-SAL

In the affix file SAL items can be used to define the sounds-a-like mechanism to be used. The main items define the "from" text and the "to" replacement. Simplistic example:

```
SAL CIA X
SAL CH X
SAL C K
SAL K K
```

There are a few rules and this can become quite complicated. An explanation how it works can be found in the Aspell manual:

<http://aspell.net/man-html/Phonetic-Code.html>.

There are a few special items:

```
SAL followup true
SAL collapse_result true
SAL remove_accents true
```

"1" has the same meaning as "true". Any other value means "false".

## **SIMPLE SOUNDFOLDING**

spell-SOFOFROM spell-SOFOTO

The SAL mechanism is complex and slow. A simpler mechanism is mapping all characters to another character, mapping similar sounding characters to the same character. At the same time this does case folding. You can not have both SAL items and simple soundfolding.

There are two items required: one to specify the characters that are mapped and one that specifies the characters they are mapped to. They must have exactly the same number of characters. Example:

```
SOF0FROM abcdefghijklmnopqrstuvwxyzABCDEFGHIJKLMN0PQRSTUVWXYZ
SOF0T0 ebctefghejklmnepkrstevvkesebctefghejklmnepkrstevvkes
```

In the example all vowels are mapped to the same character 'e'. Another method would be to leave out all vowels. Some characters that sound nearly the same and are often mixed up, such as 'm' and 'n', are mapped to the same character. Don't do this too much, all words will start looking alike.

Characters that do not appear in SOF0FROM will be left out, except that all white space is replaced by one space. Sequences of the same character in SOF0FROM are replaced by one.

You can use the `soundfold()` function to try out the results. Or set the `'verbose'` option to see the score in the output of the `z=` command.

## UNSUPPORTED ITEMS

`spell-affix-not-supported`

These items appear in the affix file of other spell checkers. In Vim they are ignored, not supported or defined in another way.

ACCENT	(Hunspell) Use MAP instead. <code>spell-MAP</code>	<code>spell-ACCENT</code>
BREAK	(Hunspell) Define break points. Unclear how it works exactly. Not supported.	<code>spell-BREAK</code>
CHECKCOMPOUNDCASE	(Hunspell) Disallow uppercase letters at compound word boundaries. Not supported.	<code>spell-CHECKCOMPOUNDCASE</code>
CHECKCOMPOUNDDUP	(Hunspell) Disallow using the same word twice in a compound. Not supported.	<code>spell-CHECKCOMPOUNDDUP</code>
CHECKCOMPOUNDREP	(Hunspell) Something about using REP items and compound words. Not supported.	<code>spell-CHECKCOMPOUNDREP</code>
CHECKCOMPOUNDTRIPLE	(Hunspell) Forbid three identical characters when compounding. Not supported.	<code>spell-CHECKCOMPOUNDTRIPLE</code>
CHECKSHARPS	(Hunspell) SS letter pair in uppercased (German) words may be upper case sharp s (ß). Not supported.	<code>spell-CHECKSHARPS</code>
COMPLEXPREFIXES	(Hunspell) Enables using two prefixes. Not supported.	<code>spell-COMPLEXPREFIXES</code>

COMPOUND	(Hunspell)	<a href="#">spell-COMPOUND</a>
	This is one line with the count of COMPOUND items, followed by that many COMPOUND lines with a pattern. Remove the first line with the count and rename the other items to COMPOUNDRULE <a href="#">spell-COMPOUNDRULE</a>	
COMPOUNDFIRST	(Hunspell)	<a href="#">spell-COMPOUNDFIRST</a>
	Use COMPOUNDRULE instead. <a href="#">spell-COMPOUNDRULE</a>	
COMPOUNDBEGIN	(Hunspell)	<a href="#">spell-COMPOUNDBEGIN</a>
	Words signed with COMPOUNDBEGIN may be first elements in compound words. Use COMPOUNDRULE instead. <a href="#">spell-COMPOUNDRULE</a>	
COMPOUNDLAST	(Hunspell)	<a href="#">spell-COMPOUNDLAST</a>
	Words signed with COMPOUNDLAST may be last elements in compound words. Use COMPOUNDRULE instead. <a href="#">spell-COMPOUNDRULE</a>	
COMPOUNDEND	(Hunspell)	<a href="#">spell-COMPOUNDEND</a>
	Probably the same as COMPOUNDLAST	
COMPOUNDMIDDLE	(Hunspell)	<a href="#">spell-COMPOUNDMIDDLE</a>
	Words signed with COMPOUNDMIDDLE may be middle elements in compound words. Use COMPOUNDRULE instead. <a href="#">spell-COMPOUNDRULE</a>	
COMPOUNDRULES	(Hunspell)	<a href="#">spell-COMPOUNDRULES</a>
	Number of COMPOUNDRULE lines following. Ignored, but the argument must be a number.	
COMPOUNDSYLLABLE	(Hunspell)	<a href="#">spell-COMPOUNDSYLLABLE</a>
	Use SYLLABLE and COMPOUNDSYLLMAX instead. <a href="#">spell-SYLLABLE</a> <a href="#">spell-COMPOUNDSYLLMAX</a>	
KEY	(Hunspell)	<a href="#">spell-KEY</a>
	Define characters that are close together on the keyboard. Used to give better suggestions. Not supported.	
LANG	(Hunspell)	<a href="#">spell-LANG</a>
	This specifies language-specific behavior. This actually moves part of the language knowledge into the program, therefore Vim does not support it. Each language property must be specified separately.	
LEMMA_PRESENT	(Hunspell)	<a href="#">spell-LEMMA_PRESENT</a>
	Only needed for morphological analysis.	
MAXNGRAMSUGS	(Hunspell)	<a href="#">spell-MAXNGRAMSUGS</a>
	Set number of n-gram suggestions. Not supported.	
PSEUDOROOT	(Hunspell)	<a href="#">spell-PSEUDOROOT</a>
	Use NEEDAFFIX instead. <a href="#">spell-NEEDAFFIX</a>	

SUGSWITHDOTS	(Hunspell) Adds dots to suggestions. Vim doesn't need this.	<a href="#">spell-SUGSWITHDOTS</a>
SYLLABLENUM	(Hunspell) Not supported.	<a href="#">spell-SYLLABLENUM</a>
TRY	(Myspell, Hunspell, others) Vim does not use the TRY item, it is ignored. For making suggestions the actual characters in the words are used, that is much more efficient.	<a href="#">spell-TRY</a>
WORDCHARS	(Hunspell) Used to recognize words. Vim doesn't need it, because there is no need to separate words before checking them (using a trie instead of a hashtable).	<a href="#">spell-WORDCHARS</a>

## VIM REFERENCE MANUAL by Bram Moolenaar

diff vimdiff gvimdiff diff-mode

This file describes the `+diff` feature: Showing differences between two to eight versions of the same file.

The basics are explained in section [08.7](#) of the user manual.

- |                       |                            |
|-----------------------|----------------------------|
| 1. Starting diff mode | <code>start-vimdiff</code> |
| 2. Viewing diffs      | <code>view-diffs</code>    |
| 3. Jumping to diffs   | <code>jumpto-diffs</code>  |
| 4. Copying diffs      | <code>copy-diffs</code>    |
| 5. Diff options       | <code>diff-options</code>  |

=====
  
1. Starting diff mode`start-vimdiff`

The easiest way to start editing in diff mode is with the `"vimdiff"` command. This starts Vim as usual, and additionally sets up for viewing the differences between the arguments.

```
vimdiff file1 file2 [file3 [file4]]
```

This is equivalent to:

```
vim -d file1 file2 [file3 [file4]]
```

You may also use `"gvimdiff"` or `"vim -d -g"`. The GUI is started then. You may also use `"viewdiff"` or `"gviewdiff"`. Vim starts in readonly mode then. `"r"` may be prepended for restricted mode (see [-Z](#)).

The second and following arguments may also be a directory name. Vim will then append the file name of the first argument to the directory name to find the file.

By default an internal diff library will be used. When `'diffopt'` or `'diffexpr'` has been set an external `"diff"` command will be used. This only works when such a diff program is available.

Diffs are local to the current tab page [tab-page](#). You can't see diffs with a window in another tab page. This does make it possible to have several diffs at the same time, each in their own tab page.

What happens is that Vim opens a window for each of the files. This is like using the `-O` argument. This uses vertical splits. If you prefer horizontal splits add the `-o` argument:

```
vimdiff -o file1 file2 [file3 [file4]]
```

If you always prefer horizontal splits include `"horizontal"` in `'diffopt'`.

In each of the edited files these options are set:

```
'diff' on
'scrollbind' on
'cursorbind' on
'scrollopt' includes "hor"
'wrap' off, or leave as-is if 'diffopt' includes "followwrap"
'foldmethod' "diff"
'foldcolumn' value from 'diffopt', default is 2
```

These options are set local to the window. When editing another file they are reset to the global value.

The options can still be overruled from a modeline when re-editing the file. However, **'foldmethod'** and **'wrap'** won't be set from a modeline when **'diff'** is set.

See `:diffoff` for an easy way to revert the options.

The differences shown are actually the differences in the buffer. Thus if you make changes after loading a file, these will be included in the displayed diffs. You might have to do `:diffupdate` now and then, not all changes are immediately taken into account, especially when using an external diff command.

In your `.vimrc` file you could do something special when Vim was started in diff mode. You could use a construct like this:

```
if &diff
 setup for diff mode
else
 setup for non-diff mode
endif
```

While already in Vim you can start diff mode in three ways.

```
:diffs[plit] {filename} E98
:diffs :diffsplit
Open a new window on the file {filename}. The options are set
as for "vimdiff" for the current and the newly opened window.
Also see 'diffexpr'.
```

```
:diff[his] :diff :diffthis
Make the current window part of the diff windows. This sets
the options like for "vimdiff".
```

```
:diffp[at]ch {patchfile} E816 :diffp :diffpatch
Use the current buffer, patch it with the diff found in
{patchfile} and open a buffer on the result. The options are
set as for "vimdiff".
{patchfile} can be in any format that the "patch" program
understands or 'patchexpr' can handle.
Note that {patchfile} should only contain a diff for one file,
the current file. If {patchfile} contains diffs for other
files as well, the results are unpredictable. Vim changes
directory to /tmp to avoid files in the current directory
```

accidentally being patched. But it may still result in various ".rej" files to be created. And when absolute path names are present these files may get patched anyway. Using the "patch" command is not allowed in `restricted-mode` .

To make these commands use a vertical split, prepend `:vertical` . Examples:

```
:vert diffsplit main.c~
:vert diffpatch /tmp/diff
```

If you always prefer a vertical split include "vertical" in `'diffopt'` .

E96

There can be up to eight buffers with `'diff'` set.

Since the option values are remembered with the buffer, you can edit another file for a moment and come back to the same file and be in diff mode again.

```
:diff[ff] :diffo :diffoff
Switch off diff mode for the current window. Resets related
options also when 'diff' was not set.

:diff[ff]! Switch off diff mode for the current window and in all windows
in the current tab page where 'diff' is set. Resetting
related options only happens in a window that has 'diff' set,
if the current window does not have 'diff' set then no options
in it are changed.
Hidden buffers are also removed from the list of diff'ed
buffers.
```

The `:`diffoff`` command resets the relevant options to the values they had when using `:`diffsplit``, `:`diffpatch``, `:`diffthis``. or starting Vim in diff mode. When using `:`diffoff`` twice the last saved values are restored. Otherwise they are set to their default value:

```
'diff' off
'scrollbind' off
'cursorbind' off
'scrollopt' without "hor"
'wrap' on, or leave as-is if 'diffopt' includes "followwrap"
'foldmethod' "manual"
'foldcolumn' 0
```

`'foldenable'` will most-likely be reset to off. That is when `'foldmethod'` is restored to "manual". The folds themselves are not cleared but they should not show up, resetting `'foldenable'` is the best way to do that.

---

## 2. Viewing diffs view-diffs

The effect is that the diff windows show the same text, with the differences highlighted. When scrolling the text, the `'scrollbind'` option will make the text in other windows to be scrolled as well. With vertical splits the text should be aligned properly.

The alignment of text will go wrong when:

- **'wrap'** is on, some lines will be wrapped and occupy two or more screen lines
- folds are open in one window but not another
- **'scrollbind'** is off
- changes have been made to the text
- "filler" is not present in **'diffopt'**, deleted/inserted lines makes the alignment go wrong

All the buffers edited in a window where the **'diff'** option is set will join in the diff. This is also possible for hidden buffers. They must have been edited in a window first for this to be possible. To get rid of the hidden buffers use `:diffoff!`.

`:DiffOrig diff-original-file`

Since **'diff'** is a window-local option, it's possible to view the same buffer in diff mode in one window and "normal" in another window. It is also possible to view the changes you have made to a buffer since the file was loaded. Since Vim doesn't allow having two buffers for the same file, you need another buffer. This command is useful:

```
command DiffOrig vert new | set bt=nofile | r ++edit # | 0d_
\ | diffthis | wincmd p | diffthis
```

(this is in `defaults.vim`). Use `:DiffOrig` to see the differences between the current buffer and the file it was loaded from.

A buffer that is unloaded cannot be used for the diff. But it does work for hidden buffers. You can use `:hide` to close a window without unloading the buffer. If you don't want a buffer to remain used for the diff do `:set nodiff` before hiding it.

`:dif :diff :diffupdate`

`:dif[fupdate][!]` Update the diff highlighting and folds.

Vim attempts to keep the differences updated when you make changes to the text. This mostly takes care of inserted and deleted lines. Changes within a line and more complicated changes do not cause the differences to be updated. To force the differences to be updated use:

`:diffupdate`

If the `!` is included Vim will check if the file was changed externally and needs to be reloaded. It will prompt for each changed file, like `:checktime` was used.

Vim will show filler lines for lines that are missing in one window but are present in another. These lines were inserted in another file or deleted in this file. Removing "filler" from the **'diffopt'** option will make Vim not display these filler lines.

Folds are used to hide the text that wasn't changed. See `folding` for all the commands that can be used with folds.

The context of lines above a difference that are not included in the fold can be set with the **'diffopt'** option. For example, to set the context to three lines:

```
:set diffopt=filler,context:3
```

The diffs are highlighted with these groups:

hl-DiffAdd	DiffAdd	Added (inserted) lines. These lines exist in this buffer but not in another.
hl-DiffChange	DiffChange	Changed lines.
hl-DiffText	DiffText	Changed text inside a Changed line. Vim finds the first character that is different, and the last character that is different (searching from the end of the line). The text in between is highlighted. This means that parts in the middle that are still the same are highlighted anyway. The <b>'diffopt'</b> flags "iwhite" and "icase" are used here.
hl-DiffDelete	DiffDelete	Deleted lines. Also called filler lines, because they don't really exist in this buffer.

---

### 3. Jumping to diffs

jumpto-diffs

Two commands can be used to jump to diffs:

[c	Jump backwards to the previous start of a change. When a count is used, do it that many times.	[c
]c	Jump forwards to the next start of a change. When a count is used, do it that many times.	]c

It is an error if there is no change for the cursor to move to.

---

### 4. Diff copying

copy-diffs E99 E100 E101 E102 E103  
merge

There are two commands to copy text from one buffer to another. The result is that the buffers will be equal within the specified range.

```
:[range]diffg[et] [bufspec] :diffg :diffget
```

Modify the current buffer to undo difference with another buffer. If [bufspec] is given, that buffer is used. If [bufspec] refers to the current buffer then nothing happens. Otherwise this only works if there is one other buffer in diff mode.  
See below for [range].

```
:[range]diffpu[t] [bufspec] :diffpu :diffput E793
```

Modify another buffer to undo difference with the current buffer. Just like `:diffget` but the other buffer is modified instead of the current one.

When `[bufspec]` is omitted and there is more than one other buffer in diff mode where `'modifiable'` is set this fails. See below for `[range]`.

`[count]``do` Same as `:diffget` without range. The "o" stands for "obtain" ("dg" can't be used, it could be the start of "dgg!"). **Note:** this doesn't work in Visual mode. If you give a `[count]`, it is used as the `[bufspec]` argument for `:diffget`.

`[count]``dp` Same as `:diffput` without range. **Note:** this doesn't work in Visual mode. If you give a `[count]`, it is used as the `[bufspec]` argument for `:diffput`.

When no `[range]` is given, the diff at the cursor position or just above it is affected. When `[range]` is used, Vim tries to only put or get the specified lines. When there are deleted lines, this may not always be possible.

There can be deleted lines below the last line of the buffer. When the cursor is on the last line in the buffer and there is no diff above this line, the `:diffget` and `do` commands will obtain lines from the other buffer.

To be able to get those lines from another buffer in a `[range]` it's allowed to use the last line number plus one. This command gets all diffs from the other buffer:

```
:1,$+1diffget
```

**Note** that deleted lines are displayed, but not counted as text lines. You can't move the cursor into them. To fill the deleted lines with the lines from another buffer use `:diffget` on the line below them.

E787

When the buffer that is about to be modified is read-only and the autocommand that is triggered by `FileChangedRO` changes buffers the command will fail. The autocommand must not change buffers.

The `[bufspec]` argument above can be a buffer number, a pattern for a buffer name or a part of a buffer name. Examples:

```
:diffget Use the other buffer which is in diff mode
:diffget 3 Use buffer 3
:diffget v2 Use the buffer which matches "v2" and is in
 diff mode (e.g., "file.c.v2")
```

=====

5. Diff options diff-options

Also see `'diffopt'` and the "diff" item of `'fillchars'` .

`diff-slow` `diff_translations`

For very long lines, the diff syntax highlighting might be slow, especially since it tries to match all different kind of localisations. To disable localisations and speed up the syntax highlighting, set the global variable `g:diff_translations` to zero:

```
let g:diff_translations = 0
```

After setting this variable, reload the syntax script:

```
set syntax=diff
```

## FINDING THE DIFFERENCES

`diff-diffexpr`

The `'diffexpr'` option can be set to use something else than the internal diff support or the standard "diff" program to compare two files and find the differences. [E959](#)

When `'diffexpr'` is empty, Vim uses this command to find the differences between file1 and file2:

```
diff file1 file2 > outfile
```

The ">" is replaced with the value of `'shellredir'`.

The output of "diff" must be a normal "ed" style diff or a unified diff. A context diff will NOT work. For a unified diff no context lines can be used. Using "diff -u" will NOT work, use "diff -U0".

This example explains the format that Vim expects for the "ed" style diff:

```
1a2
> bbb
4d4
< 111
7c7
< GGG

> ggg
```

The "1a2" item appends the line "bbb".

The "4d4" item deletes the line "111".

The "7c7" item replaces the line "GGG" with "ggg".

When `'diffexpr'` is not empty, Vim evaluates it to obtain a diff file in the format mentioned. These variables are set to the file names used:

<code>v:fname_in</code>	original file
<code>v:fname_new</code>	new version of the same file
<code>v:fname_out</code>	where to write the resulting diff file

Additionally, **'diffexpr'** should take care of "icase" and "iwhite" in the **'diffopt'** option. **'diffexpr'** cannot change the value of **'lines'** and **'columns'**.

The advantage of using a function call without arguments is that it is faster, see [expr-option-function](#) .

Example (this does almost the same as **'diffexpr'** being empty):

```
set diffexpr=MyDiff()
function MyDiff()
 let opt = ""
 if &diffopt =~ "icase"
 let opt = opt .. "-i "
 endif
 if &diffopt =~ "iwhite"
 let opt = opt .. "-b "
 endif
 silent execute "!diff -a --binary " .. opt .. v:fname_in .. " " .. v:fname_new
 \ " > " .. v:fname_out
 redraw!
endfunction
```

The "-a" argument is used to force comparing the files as text, comparing as binaries isn't useful. The "--binary" argument makes the files read in binary mode, so that a **CTRL-Z** doesn't end the text on DOS.

The ``redraw!`` command may not be needed, depending on whether executing a shell command shows something on the display or not.

If the **'diffexpr'** expression starts with s: or `<SID>` , then it is replaced with the script ID ( [local-function](#) ). Example:

```
set diffexpr=s:MyDiffExpr()
set diffexpr=<SID>SomeDiffExpr()
```

Otherwise, the expression is evaluated in the context of the script where the option was set, thus script-local items are available.

E810 E97

Vim will do a test if the diff output looks alright. If it doesn't, you will get an error message. Possible causes:

- The "diff" program cannot be executed.
- The "diff" program doesn't produce normal "ed" style diffs (see above).
- The **'shell'** and associated options are not set correctly. Try if filtering works with a command like `":!sort"`.
- You are using **'diffexpr'** and it doesn't work.

If it's not clear what the problem is set the **'verbose'** option to one or more to see more messages.

The self-installing Vim for MS-Windows includes a diff program. If you don't have it you might want to download a diff.exe. For example from <http://gnuwin32.sourceforge.net/packages/diffutils.htm>.

## USING PATCHES

diff-patchexpr

The **'patchexpr'** option can be set to use something else than the standard "patch" program.

When **'patchexpr'** is empty, Vim will call the "patch" program like this:

```
patch -o outfile origfile < patchfile
```

This should work fine with most versions of the "patch" program. **Note** that a CR in the middle of a line may cause problems, it is seen as a line break.

If the default doesn't work for you, set the **'patchexpr'** to an expression that will have the same effect. These variables are set to the file names used:

```
v:fname_in original file
v:fname_diff patch file
v:fname_out resulting patched file
```

The advantage of using a function call without arguments is that it is faster, see [expr-option-function](#) .

Example (this does the same as **'patchexpr'** being empty):

```
set patchexpr=MyPatch()
function MyPatch()
 :call system("patch -o " .. v:fname_out .. " " .. v:fname_in ..
 \ " < " .. v:fname_diff)
endfunction
```

Make sure that using the "patch" program doesn't have unwanted side effects. For example, watch out for additionally generated files, which should be deleted. It should just patch the file and nothing else.

Vim will change directory to "/tmp" or another temp directory before evaluating **'patchexpr'**. This hopefully avoids that files in the current directory are accidentally patched. Vim will also delete files starting with v:fname\_in and ending in ".rej" and ".orig".

If the **'patchexpr'** expression starts with s: or **<SID>** , then it is replaced with the script ID ( [local-function](#) ). Example:

```
set patchexpr=s:MyPatchExpr()
set patchexpr=<SID>SomePatchExpr()
```

Otherwise, the expression is evaluated in the context of the script where the option was set, thus script-local items are available.

## DIFF FUNCTION EXAMPLES

diff-func-examples

Some examples for using the [diff\(\)](#) function to compute the diff indices between two Lists of strings are below.

```
" some lines are changed
:echo diff(['abc', 'def', 'ghi'], ['abx', 'rrr', 'xhi'], {'output': 'indices'})
[{'from_idx': 0, 'from_count': 3, 'to_idx': 0, 'to_count': 3}]
```

```

" few lines added at the beginning
:echo diff(['ghi'], ['abc', 'def', 'ghi'], {'output': 'indices'})
[{'from_idx': 0, 'from_count': 0, 'to_idx': 0, 'to_count': 2}]

" few lines removed from the beginning
:echo diff(['abc', 'def', 'ghi'], ['ghi'], {'output': 'indices'})
[{'from_idx': 0, 'from_count': 2, 'to_idx': 0, 'to_count': 0}]

" few lines added in the middle
:echo diff(['abc', 'jkl'], ['abc', 'def', 'ghi', 'jkl'], {'output': 'indices'})
[{'from_idx': 1, 'from_count': 0, 'to_idx': 1, 'to_count': 2}]

" few lines removed in the middle
:echo diff(['abc', 'def', 'ghi', 'jkl'], ['abc', 'jkl'], {'output': 'indices'})
[{'from_idx': 1, 'from_count': 2, 'to_idx': 1, 'to_count': 0}]

" few lines added at the end
:echo diff(['abc'], ['abc', 'def', 'ghi'], {'output': 'indices'})
[{'from_idx': 1, 'from_count': 0, 'to_idx': 1, 'to_count': 2}]

" few lines removed from the end
:echo diff(['abc', 'def', 'ghi'], ['abc'], {'output': 'indices'})
[{'from_idx': 1, 'from_count': 2, 'to_idx': 1, 'to_count': 0}]

" disjointed changes
:echo diff(['ab', 'def', 'ghi', 'jkl'], ['abc', 'def', 'ghi', 'jk'], {'output': 'indices'})
[{'from_idx': 0, 'from_count': 1, 'to_idx': 0, 'to_count': 1},
 {'from_idx': 3, 'from_count': 1, 'to_idx': 3, 'to_count': 1}]

" disjointed changes with context length 1
:echo diff(['ab', 'def', 'ghi', 'jkl'], ['abc', 'def', 'ghi', 'jk'], {'output': 'indices'})
[{'from_idx': 0, 'from_count': 4, 'to_idx': 0, 'to_count': 4}]

```

## 1. Introduction

[autocmd-intro](#)

You can specify commands to be executed automatically when reading or writing a file, when entering or leaving a buffer or window, and when exiting Vim. For example, you can create an autocommand to set the **'cindent'** option for files matching \*.c. You can also use autocommands to implement advanced features, such as editing compressed files (see [gzip-example](#)). The usual place to put autocommands is in your .vimrc or .exrc file.

[E203](#) [E204](#) [E143](#) [E855](#) [E937](#) [E952](#)

WARNING: Using autocommands is very powerful, and may lead to unexpected side effects. Be careful not to destroy your text.

- It's a good idea to do some testing on an expendable copy of a file first. For example: If you use autocommands to decompress a file when starting to edit it, make sure that the autocommands for compressing when writing work correctly.
- Be prepared for an error halfway through (e.g., disk full). Vim will mostly be able to undo the changes to the buffer, but you may have to clean up the changes to other files by hand (e.g., compress a file that has been decompressed).
- If the BufRead\* events allow you to edit a compressed file, the FileRead\* events should do the same (this makes recovery possible in some rare cases). It's a good idea to use the same autocommands for the File\* and Buf\* events when possible.

Recommended use:

- Always use a group, so that it's easy to delete the autocommand.
- Keep the command itself short, call a function to do more work.
- Make it so that the script it is defined in can be sourced several times without the autocommand being repeated.

Example in Vim9 script:

```
autocmd_add([{\replace: true,
 group: 'DemoGroup',
 event: 'BufEnter',
 pattern: '*.txt',
 cmd: 'call DemoBufEnter()'
 }]])
```

In legacy script:

```
call autocmd_add([#\replace: v:true,
 \ group: 'DemoGroup',
 \ event: 'BufEnter',
 \ pattern: '*.txt',
 \ cmd: 'call DemoBufEnter()'
 \]])
```

---

## 2. Defining autocommands

[autocmd-define](#)

```
:au[tocmd] [group] {event} {aupat} [++once] [++nested] {cmd}
 :au :autocmd
Add {cmd} to the list of commands that Vim will
execute automatically on {event} for a file matching
{aupat} autocmd-patterns .
Here {event} cannot be "*". E1155
Note: A quote character is seen as argument to the
:autocmd and won't start a comment.
Vim always adds the {cmd} after existing autocommands,
so that the autocommands execute in the order in which
they were given.
See autocmd-nested for [++nested]. "nested"
(without the ++) can also be used, for backwards
compatibility, but not in Vim9 script. E1078
autocmd-once
If [++once] is supplied the command is executed once,
then removed ("one shot").
```

The special pattern `<buffer>` or `<buffer=N>` defines a buffer-local autocommand. See [autocmd-buflocal](#) .

If the `:autocmd` is in Vim9 script (a script that starts with `:vim9script` and in a `:def` function) then {cmd} will be executed as in Vim9 script. Thus this depends on where the autocmd is defined, not where it is triggered.

[autocmd-block](#)  
{cmd} can be a block, like with `:command`, see [:command-repl](#) . Example:

```
au BufReadPost *.xml {
 setlocal matchpairs+=<:>
 /<start
}
```

The `autocmd_add()` function can be used to add a list of autocmds and autocmd groups from a Vim script. It is preferred if you have anything that would

require using `:execute` with `:autocmd`.

**Note:** The `:autocmd` command can only be followed by another command when the `'|'` appears where the pattern is expected. This works:

```
:augroup mine | au! BufRead | augroup END
```

But this sees "augroup" as part of the defined command:

```
:augroup mine | au! BufRead * | augroup END
:augroup mine | au BufRead * set tw=70 | augroup END
```

Instead you can put the group name into the command:

```
:au! mine BufRead *
:au mine BufRead * set tw=70
```

Or use `:execute`:

```
:augroup mine | exe "au! BufRead *" | augroup END
:augroup mine | exe "au BufRead * set tw=70" | augroup END
```

#### autocmd-expand

**Note** that special characters (e.g., "%", "<cword>") in the `:autocmd` arguments are not expanded when the autocommand is defined. These will be expanded when the Event is recognized, and the `{cmd}` is executed. The only exception is that `<sfile>` is expanded when the `autocmd` is defined. Example:

```
:au BufNewFile,BufRead *.html so <sfile>:h/html.vim
```

Here Vim expands `<sfile>` to the name of the file containing this line.

`:autocmd` adds to the list of autocommands regardless of whether they are already present. When your `.vimrc` file is sourced twice, the autocommands will appear twice. To avoid this, define your autocommands in a group, so that you can easily clear them:

```
augroup vimrc
 " Remove all vimrc autocommands
 autocmd!
 au BufNewFile,BufRead *.html so <sfile>:h/html.vim
augroup END
```

If you don't want to remove all autocommands, you can instead use a variable to ensure that Vim includes the autocommands only once:

```
:if !exists("autocommands_loaded")
: let autocommands_loaded = 1
: au ...
:endif
```

When the `[group]` argument is not given, Vim uses the current group (as defined with `:augroup`); otherwise, Vim uses the group defined with `[group]`. **Note** that `[group]` must have been defined before. You cannot define a new group with `:au group ...`; use `:augroup` for that.

While testing autocommands, you might find the **'verbose'** option to be useful:

```
:set verbose=9
```

This setting makes Vim echo the autocommands as it executes them.

When defining an autocommand in a script, it will be able to call functions

local to the script and use mappings local to the script. When the event is triggered and the command executed, it will run in the context of the script it was defined in. This matters if `<SID>` is used in a command.

When executing the commands, the message from one command overwrites a previous message. This is different from when executing the commands manually. Mostly the screen will not scroll up, thus there is no hit-enter prompt. When one command outputs two messages this can happen anyway.

---

### 3. Removing autocommands

`autocmd-remove`

In addition to the below described commands, the `autocmd_delete()` function can be used to remove a list of autocmds and autocmd groups from a Vim script.

```
:au[tocmd]! [group] {event} {aupat} [++once] [++nested] {cmd}
 Remove all autocommands associated with {event} and
 {aupat}, and add the command {cmd}.
 See autocmd-once for [++once].
 See autocmd-nested for [++nested].
```

```
:au[tocmd]! [group] {event} {aupat}
 Remove all autocommands associated with {event} and
 {aupat}.
```

```
:au[tocmd]! [group] * {aupat}
 Remove all autocommands associated with {aupat} for
 all events.
```

```
:au[tocmd]! [group] {event}
 Remove ALL autocommands for {event}.
 Warning: You should not do this without a group for
 BufRead and other common events, it can break
 plugins, syntax highlighting, etc.
```

```
:au[tocmd]! [group]
 Remove ALL autocommands.
 Note: a quote will be seen as argument to the :autocmd
 and won't start a comment.
 Warning: You should normally not do this without a
 group, it breaks plugins, syntax highlighting, etc.
```

When the `[group]` argument is not given, Vim uses the current group (as defined with `":augroup"`); otherwise, Vim uses the group defined with `[group]`.

---

### 4. Listing autocommands

`autocmd-list`

```
:au[tocmd] [group] {event} {aupat}
 Show the autocommands associated with {event} and
 {aupat}.
```

```
:au[tocmd] [group] * {aupat}
 Show the autocommands associated with {aupat} for all
 events.
```

```
:au[tocmd] [group] {event}
 Show all autocmds for {event}.
```

```
:au[tocmd] [group] Show all autocmds.
```

If you provide the `[group]` argument, Vim lists only the autocmds for `[group]`; otherwise, Vim lists the autocmds for ALL groups. **Note** that this argument behavior differs from that for defining and removing autocmds.

In order to list buffer-local autocmds, use a pattern in the form `<buffer>` or `<buffer=N>`. See `autocmd-buflocal`.

The `autocmd_get()` function can be used from a Vim script to get a list of autocmds.

`:autocmd-verbose`

When **'verbose'** is non-zero, listing an autocmd will also display where it was last defined. Example:

```
:verbose autocmd BufEnter
FileExplorer BufEnter
* call s:LocalBrowse(expand("<amatch>"))
 Last set from /usr/share/vim/vim-7.0/plugin/NetrwPlugin.vim
```

See `:verbose-cmd` for more information.

---

## 5. Events

`autocmd-events` `E215` `E216`

You can specify a comma-separated list of event names. No white space can be used in this list. The command applies to all the events in the list.

For READING FILES there are four kinds of events possible:

BufNewFile		starting to edit a non-existent file
BufReadPre	BufReadPost	starting to edit an existing file
FilterReadPre	FilterReadPost	read the temp file with filter output
FileReadPre	FileReadPost	any other file read

Vim uses only one of these four kinds when reading a file. The "Pre" and "Post" events are both triggered, before and after reading the file.

**Note** that the autocmds for the `*ReadPre` events and all the Filter events are not allowed to change the current buffer (you will get an error message if this happens). This is to prevent the file to be read into the wrong buffer.

**Note** that the **'modified'** flag is reset AFTER executing the `BufReadPost` and `BufNewFile` autocmds. But when the **'modified'** option was set by the autocmds, this doesn't happen.

You can use the **'eventignore'** option to ignore a number of events or all events.

`autocommand-events` `{event}`

Vim recognizes the following events. Vim ignores the case of event names (e.g., you can use "BURead" or "bufread" instead of "BufRead").

First an overview by function with a short explanation. Then the list alphabetically with full explanations [autocmd-events-abc](#) .

Name	triggered by
Reading	
BufNewFile	starting to edit a file that doesn't exist
BufReadPre	starting to edit a new buffer, before reading the file
BufRead	starting to edit a new buffer, after reading the file
BufReadPost	starting to edit a new buffer, after reading the file
BufReadCmd	before starting to edit a new buffer <a href="#">Cmd-event</a>
FileReadPre	before reading a file with a ":read" command
FileReadPost	after reading a file with a ":read" command
FileReadCmd	before reading a file with a ":read" command <a href="#">Cmd-event</a>
FilterReadPre	before reading a file from a filter command
FilterReadPost	after reading a file from a filter command
StdinReadPre	before reading from stdin into the buffer
StdinReadPost	After reading from the stdin into the buffer
Writing	
BufWrite	starting to write the whole buffer to a file
BufWritePre	starting to write the whole buffer to a file
BufWritePost	after writing the whole buffer to a file
BufWriteCmd	before writing the whole buffer to a file <a href="#">Cmd-event</a>
FileWritePre	starting to write part of a buffer to a file
FileWritePost	after writing part of a buffer to a file
FileWriteCmd	before writing part of a buffer to a file <a href="#">Cmd-event</a>
FileAppendPre	starting to append to a file
FileAppendPost	after appending to a file
FileAppendCmd	before appending to a file <a href="#">Cmd-event</a>
FilterWritePre	starting to write a file for a filter command or diff
FilterWritePost	after writing a file for a filter command or diff
Buffers	
BufAdd	just after adding a buffer to the buffer list
BufCreate	just after adding a buffer to the buffer list
BufDelete	before deleting a buffer from the buffer list
BufWipeout	before completely deleting a buffer
BufFilePre	before changing the name of the current buffer
BufFilePost	after changing the name of the current buffer
BufEnter	after entering a buffer
BufLeave	before leaving to another buffer
BufWinEnter	after a buffer is displayed in a window
BufWinLeave	before a buffer is removed from a window

BufUnload	before unloading a buffer
BufHidden	just before a buffer becomes hidden
BufNew	just after creating a new buffer
SwapExists	detected an existing swap file
Options	
FileType	when the <b>'filetype'</b> option has been set
Syntax	when the <b>'syntax'</b> option has been set
EncodingChanged	after the <b>'encoding'</b> option has been changed
TermChanged	after the value of <b>'term'</b> has changed
OptionSet	after setting any option
Startup and exit	
VimEnter	after doing all the startup stuff
GUIEnter	after starting the GUI successfully
GUIFailed	after starting the GUI failed
TermResponse	after the terminal response to <code>t_RV</code> is received
TermResponseAll	after the terminal response to <code>t_RV</code> and others is received
QuitPre	when using <code>:quit</code> , before deciding whether to exit
ExitPre	when using a command that may make Vim exit
VimLeavePre	before exiting Vim, before writing the viminfo file
VimLeave	before exiting Vim, after writing the viminfo file
VimSuspend	when suspending Vim
VimResume	when Vim is resumed after being suspended
Terminal	
TerminalOpen	after a terminal buffer was created
TerminalWinOpen	after a terminal buffer was created in a new window
Various	
FileChangedShell	Vim notices that a file changed since editing started
FileChangedShellPost	After handling a file changed since editing started
FileChangedRO	before making the first change to a read-only file
DiffUpdated	after diffs have been updated
DirChangedPre	before the working directory will change
DirChanged	after the working directory has changed
ShellCmdPost	after executing a shell command
ShellFilterPost	after filtering with a shell command
CmdUndefined	a user command is used but it isn't defined
FuncUndefined	a user function is used but it isn't defined
SpellFileMissing	a spell file is used but it can't be found
SourcePre	before sourcing a Vim script
SourcePost	after sourcing a Vim script
SourceCmd	before sourcing a Vim script <a href="#">Cmd-event</a>
VimResized	after the Vim window size changed
FocusGained	Vim got input focus
FocusLost	Vim lost input focus

CursorHold	the user doesn't press a key for a while
CursorHoldI	the user doesn't press a key for a while in Insert mode
CursorMoved	the cursor was moved in Normal mode
CursorMovedC	the cursor was moved in the <a href="#">Command-line</a>
CursorMovedI	the cursor was moved in Insert mode
WinNewPre	before creating a new window
WinNew	after creating a new window
TabNew	after creating a new tab page
WinClosed	after closing a window
TabClosed	after closing a tab page
TabClosedPre	before closing a tab page
WinEnter	after entering another window
WinLeave	before leaving a window
TabEnter	after entering another tab page
TabLeave	before leaving a tab page
CmdwinEnter	after entering the command-line window
CmdwinLeave	before leaving the command-line window
CmdlineChanged	after a change was made to the command-line text
CmdlineEnter	after the cursor moves to the command line
CmdlineLeave	before the cursor leaves the command line
InsertEnter	starting Insert mode
InsertChange	when typing <a href="#">&lt;Insert&gt;</a> while in Insert or Replace mode
InsertLeave	when leaving Insert mode
InsertLeavePre	just before leaving Insert mode
InsertCharPre	when a character was typed in Insert mode, before inserting it
ModeChanged	after changing the mode
TextChanged	after a change was made to the text in Normal mode
TextChangedI	after a change was made to the text in Insert mode when popup menu is not visible
TextChangedP	after a change was made to the text in Insert mode when popup menu visible
TextChangedT	after a change was made to the text in Terminal mode
TextYankPost	after text has been yanked or deleted
SafeState	nothing pending, going to wait for the user to type a character
SafeStateAgain	repeated SafeState
ColorSchemePre	before loading a color scheme
ColorScheme	after loading a color scheme
RemoteReply	a reply from a server Vim was received
QuickFixCmdPre	before a quickfix command is run
QuickFixCmdPost	after a quickfix command is run
SessionLoadPost	after loading a session file

SessionWritePost	after writing the session file using the <code>:mksession</code> command
MenuPopup	just before showing the popup menu
CompleteChanged	after Insert mode completion menu changed
CompleteDonePre	after Insert mode completion is done, before clearing info
CompleteDone	after Insert mode completion is done, after clearing info
KeyInputPre	just before a key is processed
User	to be used in combination with <code>":doautocmd"</code>
SigUSR1	after the SIGUSR1 signal has been detected
WinScrolled	after scrolling or resizing a window

The alphabetical list of autocommand events: [autocmd-events-abc](#)

	<a href="#">BufCreate</a> <a href="#">BufAdd</a>
BufAdd or BufCreate	Just after creating a new buffer which is added to the buffer list, or adding a buffer to the buffer list. Also used just after a buffer in the buffer list has been renamed. Not triggered for the initial buffers created during startup. The BufCreate event is for historic reasons. <b>NOTE:</b> When this autocommand is executed, the current buffer "%" may be different from the buffer being created "<afile>".
	<a href="#">BufDelete</a>
BufDelete	Before deleting a buffer from the buffer list. The BufUnload may be called first (if the buffer was loaded). Also used just before a buffer in the buffer list is renamed. <b>NOTE:</b> When this autocommand is executed, the current buffer "%" may be different from the buffer being deleted "<afile>" and "<abuf>". Don't change to another buffer, it will cause problems.
	<a href="#">BufEnter</a>
BufEnter	After entering a buffer. Useful for setting options for a file type. Also executed when starting to edit a buffer, after the BufReadPost autocommands.
	<a href="#">BufFilePost</a>
BufFilePost	After changing the name of the current buffer with the <code>":file"</code> or <code>":saveas"</code> command.
	<a href="#">BufFilePre</a>
BufFilePre	Before changing the name of the current buffer with the <code>":file"</code> or <code>":saveas"</code> command.

BufHidden	<p style="text-align: right;"><b>BufHidden</b></p> <p>Just before a buffer becomes hidden. That is, when there are no longer windows that show the buffer, but the buffer is not unloaded or deleted. Not used for ":qa" or ":q" when exiting Vim.</p> <p><b>NOTE:</b> When this autocommand is executed, the current buffer "%" may be different from the buffer being unloaded "&lt;afile&gt;".</p>
BufLeave	<p style="text-align: right;"><b>BufLeave</b></p> <p>Before leaving to another buffer. Also when leaving or closing the current window and the new current window is not for the same buffer. Not used for ":qa" or ":q" when exiting Vim.</p>
BufNew	<p style="text-align: right;"><b>BufNew</b></p> <p>Just after creating a new buffer. Also used just after a buffer has been renamed. When the buffer is added to the buffer list BufAdd will be triggered too.</p> <p><b>NOTE:</b> When this autocommand is executed, the current buffer "%" may be different from the buffer being created "&lt;afile&gt;".</p>
BufNewFile	<p style="text-align: right;"><b>BufNewFile</b></p> <p>When starting to edit a file that doesn't exist. Can be used to read in a skeleton file.</p>
BufRead or BufReadPost	<p style="text-align: right;"><b>BufRead    BufReadPost</b></p> <p>When starting to edit a new buffer, after reading the file into the buffer, before executing the modelines. See <a href="#">BufWinEnter</a> for when you need to do something after processing the modelines.</p> <p>Also triggered:</p> <ul style="list-style-type: none"> <li>- when writing an unnamed buffer in a way that the buffer gets a name</li> <li>- after successfully recovering a file</li> <li>- for the filetypedetect group when executing ":filetype detect"</li> </ul> <p>Not triggered:</p> <ul style="list-style-type: none"> <li>- for the `:read file` command</li> <li>- when the file doesn't exist</li> </ul>
BufReadCmd	<p style="text-align: right;"><b>BufReadCmd</b></p> <p>Before starting to edit a new buffer. Should read the file into the buffer. <a href="#">Cmd-event</a></p>
BufReadPre	<p style="text-align: right;"><b>BufReadPre    E200    E201</b></p> <p>When starting to edit a new buffer, before reading the file into the buffer. Not used if the file doesn't exist.</p>
BufUnload	<p style="text-align: right;"><b>BufUnload</b></p> <p>Before unloading a buffer. This is when the text in the buffer is going to be freed. This may be after a BufWritePost and before a BufDelete. Also used for all buffers that are loaded when Vim is going to exit.</p>

**NOTE:** When this autocommand is executed, the current buffer "%" may be different from the buffer being unloaded "<afile>".

Don't change to another buffer or window, it will cause problems!

When exiting and v:dying is 2 or more this event is not triggered.

BufWinEnter

BufWinEnter

After a buffer is displayed in a window. This can be when the buffer is loaded (after processing the modelines) or when a hidden buffer is displayed in a window (and is no longer hidden).

Does not happen for :split without arguments, since you keep editing the same buffer, or ":split" with a file that's already open in a window, because it re-uses an existing buffer. But it does happen for a ":split" with the name of the current buffer, since it reloads that buffer.

Does not happen for a terminal window, because it starts in Terminal-Job mode and Normal mode commands won't work. Use TerminalOpen instead.

BufWinLeave

BufWinLeave

Before a buffer is removed from a window.

Not when it's still visible in another window. Also triggered when exiting. It's triggered before BufUnload or BufHidden.

**NOTE:** When this autocommand is executed, the current buffer "%" may be different from the buffer being unloaded "<afile>".

When exiting and v:dying is 2 or more this event is not triggered.

BufWipeout

BufWipeout

Before completely deleting a buffer. The BufUnload and BufDelete events may be called first (if the buffer was loaded and was in the buffer list). Also used just before a buffer is renamed (also when it's not in the buffer list).

**NOTE:** When this autocommand is executed, the current buffer "%" may be different from the buffer being deleted "<afile>".

Don't change to another buffer, it will cause problems.

BufWrite or BufWritePre

BufWrite BufWritePre

Before writing the whole buffer to a file.

BufWriteCmd

BufWriteCmd

Before writing the whole buffer to a file. Should do the writing of the file and reset 'modified' if successful, unless '+' is in 'cpo' and writing to another file cpo-+ . The buffer contents should not be changed. When the command resets 'modified' the undo

information is adjusted to mark older undo states as **'modified'**, like `:write` does.

`Cmd-event`

`BufWritePost`

BufWritePost

After writing the whole buffer to a file (should undo the commands for BufWritePre).

`CmdUndefined`

CmdUndefined

When a user command is used but it isn't defined. Useful for defining a command only when it's used. The pattern is matched against the command name. Both `<amatch>` and `<afile>` are set to the name of the command. This is triggered even when inside an autocommand defined without `autocmd-nested`.  
**NOTE:** Autocompletion won't work until the command is defined. An alternative is to always define the user command and have it invoke an autoloading function. See `autoload`.

`CmdlineChanged`

CmdlineChanged

After a change was made to the text in the command line. Be careful not to mess up the command line, it may cause Vim to lock up. `<afile>` is set to a single character, indicating the type of command-line.

`cmdwin-char`

`CmdlineEnter`

CmdlineEnter

After moving the cursor to the command line, where the user can type a command or search string; including non-interactive use of ":" in a mapping, but not when using `<Cmd>`. The pattern is matched against the character representing the type of command-line.

`cmdwin-char`

`<afile>` is set to a single character, indicating the type of command-line.

`CmdlineLeave`

CmdlineLeave

Before leaving the command line; including non-interactive use of ":" in a mapping, but not when using `<Cmd>`.

Also when abandoning the command line, after typing **CTRL-C** or `<Esc>`.

When the commands result in an error the command line is still executed.

`<afile>` is set to a single character, indicating the type of command-line.

`cmdwin-char`

`CmdwinEnter`

CmdwinEnter

After entering the command-line window. Useful for setting options specifically for this special type of window.

`<afile>` is set to a single character, indicating the type of command-line.

`cmdwin-char`

`CmdwinLeave`

CmdwinLeave	<p>Before leaving the command-line window. Useful to clean up any global setting done with CmdwinEnter.</p> <p><code>&lt;afile&gt;</code> is set to a single character, indicating the type of command-line.</p> <p><code>cmdwin-char</code></p>														
ColorScheme	<p><b>ColorScheme</b></p> <p>After loading a color scheme. <code>:colorscheme</code></p> <p>Not triggered if the color scheme is not found.</p> <p>The pattern is matched against the colorscheme name. <code>&lt;afile&gt;</code> can be used for the name of the actual file where this option was set, and <code>&lt;amatch&gt;</code> for the new colorscheme name.</p>														
ColorSchemePre	<p><b>ColorSchemePre</b></p> <p>Before loading a color scheme. <code>:colorscheme</code></p> <p>Useful to setup removing things added by a color scheme, before another one is loaded.</p>														
CompleteChanged	<p><b>CompleteChanged</b></p> <p>After each time the Insert mode completion menu changed. Not fired on popup menu hide, use <code>CompleteDonePre</code> or <code>CompleteDone</code> for that. Never triggered recursively.</p> <p>Sets these <code>v:event</code> keys:</p> <table> <tr> <td><code>completed_item</code></td> <td>See <code>complete-items</code> .</td> </tr> <tr> <td><code>height</code></td> <td>nr of items visible</td> </tr> <tr> <td><code>width</code></td> <td>screen cells</td> </tr> <tr> <td><code>row</code></td> <td>top screen row</td> </tr> <tr> <td><code>col</code></td> <td>leftmost screen column</td> </tr> <tr> <td><code>size</code></td> <td>total nr of items</td> </tr> <tr> <td><code>scrollbar</code></td> <td>TRUE if visible</td> </tr> </table> <p>It is not allowed to change the text <code>textlock</code> .</p> <p>The size and position of the popup are also available by calling <code>pum_getpos()</code> .</p>	<code>completed_item</code>	See <code>complete-items</code> .	<code>height</code>	nr of items visible	<code>width</code>	screen cells	<code>row</code>	top screen row	<code>col</code>	leftmost screen column	<code>size</code>	total nr of items	<code>scrollbar</code>	TRUE if visible
<code>completed_item</code>	See <code>complete-items</code> .														
<code>height</code>	nr of items visible														
<code>width</code>	screen cells														
<code>row</code>	top screen row														
<code>col</code>	leftmost screen column														
<code>size</code>	total nr of items														
<code>scrollbar</code>	TRUE if visible														
CompleteDonePre	<p><b>CompleteDonePre</b></p> <p>After Insert mode completion is done. Either when something was completed or abandoning completion. <code>ins-completion</code></p> <p><code>complete_info()</code> can be used, the info is cleared after triggering CompleteDonePre. The <code>v:completed_item</code> variable contains information about the completed item.</p>														
CompleteDone	<p><b>CompleteDone</b></p> <p>After Insert mode completion is done. Either when something was completed or abandoning completion. <code>ins-completion</code></p> <p><code>complete_info()</code> cannot be used, the info is</p>														

cleared before triggering CompleteDone. Use CompleteDonePre if you need it. The `v:completed_item` variable contains information about the completed item.

Sets these `v:event` keys:

<code>complete_word</code>	The word that was selected, empty if abandoned complete.
<code>complete_type</code>	<code>complete_info_mode</code>

### CursorHold

CursorHold

When the user doesn't press a key for the time specified with `'updatetime'`. Not triggered until the user has pressed a key (i.e. doesn't fire every `'updatetime'` ms if you leave Vim to make some coffee. :) See [CursorHold-example](#) for previewing tags.

This event is only triggered in Normal mode. It is not triggered when waiting for a command argument to be typed, or a movement after an operator.

While recording the CursorHold event is not triggered. `q`

### <CursorHold>

Internally the autocommand is triggered by the `<CursorHold>` key. In an expression mapping `getchar()` may see this character.

**Note:** Interactive commands cannot be used for this event. There is no hit-enter prompt, the screen is updated directly (when needed).

**Note:** In the future there will probably be another option to set the time.

**Hint:** to force an update of the status lines use:

```
:let &ro = &ro
```

{only on Amiga, Unix, Win32 and all GUI versions}

### CursorHoldI

CursorHoldI

Just like CursorHold, but in Insert mode.

Not triggered when waiting for another key, e.g. after **CTRL-V**, and not when in **CTRL-X** mode `insert_expand`.

### CursorMoved

CursorMoved

After the cursor was moved in Normal or Visual mode. Also when the text of the cursor line has been changed, e.g., with "x", "rx" or "p". Not always triggered when there is typeahead, while executing commands in a script file, when an operator is pending or when moving to another window while remaining at the same cursor position.

For an example see [match-parens](#) .  
**Note:** This can not be skipped with  
``:noautocmd``.

Careful: This is triggered very often, don't do anything that the user does not expect or that is slow.

CursorMovedC	<p style="text-align: right;"><b>CursorMovedC</b></p> After the cursor was moved in the command line. Be careful not to mess up the command line, it may cause Vim to lock up. <code>&lt;afile&gt;</code> is set to a single character, indicating the type of command-line. <a href="#">cmdwin-char</a>
CursorMovedI	<p style="text-align: right;"><b>CursorMovedI</b></p> After the cursor was moved in Insert mode. Not triggered when the popup menu is visible. Otherwise the same as CursorMoved.
DiffUpdated	<p style="text-align: right;"><b>DiffUpdated</b></p> After diffs have been updated. Depending on what kind of diff is being used (internal or external) this can be triggered on every change or when doing <code>:diffupdate</code> .
DirChangedPre	<p style="text-align: right;"><b>DirChangedPre</b></p> The working directory is going to be changed, as with <a href="#">DirChanged</a> . The pattern is like with <a href="#">DirChanged</a> . The new directory can be found in <code>v:event.directory</code> .
DirChanged	<p style="text-align: right;"><b>DirChanged</b></p> The working directory has changed in response to the <code>:cd</code> or <code>:tcd</code> or <code>:lcd</code> commands, or as a result of the <code>'autochdir'</code> option. The pattern can be: "window" to trigger on <code>`:lcd`</code> "tabpage" to trigger on <code>`:tcd`</code> "global" to trigger on <code>`:cd`</code> "auto" to trigger on <code>'autochdir'</code> . "drop" to trigger on editing a file <code>&lt;afile&gt;</code> is set to the new directory name.
EncodingChanged	<p style="text-align: right;"><b>EncodingChanged</b></p> Fires off after the <code>'encoding'</code> option has been changed. Useful to set up fonts, for example.
ExitPre	<p style="text-align: right;"><b>ExitPre</b></p> When using <code>:quit`</code> , <code>:wq`</code> in a way it makes Vim exit, or using <code>:qall`</code> , just after <a href="#">QuitPre</a> . Can be used to close any non-essential window. Exiting may still be cancelled if there is a modified buffer that isn't automatically saved, use <a href="#">VimLeavePre</a> for really exiting.
FileAppendCmd	<p style="text-align: right;"><b>FileAppendCmd</b></p> Before appending to a file. Should do the appending to the file. Use the <code>'[</code> and <code>']</code> marks for the range of lines. <a href="#">Cmd-event</a> <p style="text-align: right;"><b>FileAppendPost</b></p>

FileAppendPost	After appending to a file. <a href="#">FileAppendPre</a>
FileAppendPre	Before appending to a file. Use the '[' and ']' marks for the range of lines. <a href="#">FileChangedRO</a>
FileChangedRO	Before making the first change to a read-only file. Can be used to check-out the file from a source control system. Not triggered when the change was caused by an autocommand. This event is triggered when making the first change in a buffer or the first change after <b>'readonly'</b> was set, just before the change is applied to the text. WARNING: If the autocommand moves the cursor the effect of the change is undefined. <a href="#">E788</a> It is not allowed to change to another buffer here. You can reload the buffer but not edit another one. <a href="#">E881</a> If the number of lines changes saving for undo may fail and the change will be aborted. <a href="#">FileChangedShell</a>
FileChangedShell	When Vim notices that the modification time of a file has changed since editing started. Also when the file attributes of the file change or when the size of the file changes. <a href="#">timestamp</a> Mostly triggered after executing a shell command, but also with a <a href="#">:checktime</a> command or when gvim regains input focus. This autocommand is triggered for each changed file. It is not used when <b>'autoread'</b> is set and the buffer was not changed. If a FileChangedShell autocommand is present the warning message and prompt is not given. The <a href="#">v:fcs_reason</a> variable is set to indicate what happened and <a href="#">v:fcs_choice</a> can be used to tell Vim what to do next. <b>NOTE:</b> When this autocommand is executed, the current buffer "%" may be different from the buffer that was changed, which is in "<afile>". <b>NOTE:</b> The commands must not change the current buffer, jump to another buffer or delete a buffer. <a href="#">E246</a> <a href="#">E811</a> <b>NOTE:</b> This event never nests, to avoid an endless loop. This means that while executing commands for the FileChangedShell event no other FileChangedShell event will be triggered. <a href="#">FileChangedShellPost</a>
FileChangedShellPost	After handling a file that was changed outside of Vim. Can be used to update the statusline. <a href="#">FileEncoding</a>

FileEncoding	Obsolete. It still works and is equivalent to <a href="#">EncodingChanged</a> .
FileReadCmd	Before reading a file with a <code>":read"</code> command. Should do the reading of the file. <a href="#">Cmd-event</a> <a href="#">FileReadCmd</a>
FileReadPost	After reading a file with a <code>":read"</code> command. <a href="#">Note</a> that Vim sets the <code>'[</code> and <code>']</code> marks to the first and last line of the read. This can be used to operate on the lines just read. <a href="#">FileReadPost</a>
FileReadPre	Before reading a file with a <code>":read"</code> command. <a href="#">FileReadPre</a>
FileType	When the <code>'filetype'</code> option has been set. The pattern is matched against the filetype. <code>&lt;afile&gt;</code> can be used for the name of the file where this option was set, and <code>&lt;amatch&gt;</code> for the new value of <code>'filetype'</code> . Navigating to another window or buffer is not allowed. See <a href="#">filetypes</a> . <a href="#">FileType</a>
FileWriteCmd	Before writing to a file, when not writing the whole buffer. Should do the writing to the file. Should not change the buffer. Use the <code>'[</code> and <code>']</code> marks for the range of lines. <a href="#">Cmd-event</a> <a href="#">FileWriteCmd</a>
FileWritePost	After writing to a file, when not writing the whole buffer. <a href="#">FileWritePost</a>
FileWritePre	Before writing to a file, when not writing the whole buffer. Use the <code>'[</code> and <code>']</code> marks for the range of lines. <a href="#">FileWritePre</a>
FilterReadPost	After reading a file from a filter command. Vim checks the pattern against the name of the current buffer as with <code>FilterReadPre</code> . Not triggered when <code>'shelltemp'</code> is off. <a href="#">FilterReadPost</a>
FilterReadPre	Before reading a file from a filter command. Vim checks the pattern against the name of the current buffer, not the name of the temporary file that is the output of the filter command. Not triggered when <code>'shelltemp'</code> is off. <a href="#">FilterReadPre</a> <a href="#">E135</a>
FilterWritePost	After writing a file for a filter command or making a diff with an external diff (see <a href="#">DiffUpdated</a> for internal diff). Vim checks the pattern against the name of the current buffer as with <code>FilterWritePre</code> . Not triggered when <code>'shelltemp'</code> is off. <a href="#">FilterWritePost</a>
FilterWritePre	Before writing a file for a filter command or <a href="#">FilterWritePre</a>

making a diff with an external diff. Vim checks the pattern against the name of the current buffer, not the name of the temporary file that is the output of the filter command.

Not triggered when `'shelltemp'` is off.

#### FocusGained

FocusGained

When Vim got input focus. Only for the GUI version and a few console versions where this can be detected. `xterm-focus-event`

#### FocusLost

FocusLost

When Vim lost input focus. Only for the GUI version and a few console versions where this can be detected. `xterm-focus-event`

May also happen when a dialog pops up.

#### FuncUndefined

FuncUndefined

When a user function is used but it isn't defined. Useful for defining a function only when it's used. The pattern is matched against the function name. Both `<amatch>` and `<afile>` are set to the name of the function. This is triggered even when inside an autocommand defined without `autocmd-nested`, but not triggered when compiling a Vim9 function.

**NOTE:** When writing Vim scripts a better alternative is to use an autoloading function. See `autoload-functions`.

#### GUIEnter

GUIEnter

After starting the GUI successfully, and after opening the window. It is triggered before `VimEnter` when using `gvim`. Can be used to position the window from a `.gvimrc` file:

```
:autocmd GUIEnter * winpos 100 50
```

#### GUIFailed

GUIFailed

After starting the GUI failed. Vim may continue to run in the terminal, if possible (only on Unix and alikes, when connecting the X server fails). You may want to quit Vim:

```
:autocmd GUIFailed * qall
```

#### InsertChange

InsertChange

When typing `<Insert>` while in Insert or Replace mode. The `v:insertmode` variable indicates the new mode.

Be careful not to move the cursor or do anything else that the user does not expect.

#### InsertCharPre

InsertCharPre

When a character is typed in Insert mode, before inserting the char.

The `v:char` variable indicates the char typed and can be changed during the event to insert a different character. When `v:char` is set to more than one character this text is inserted literally.

It is not allowed to change the text `textlock` .  
The event is not triggered when `'paste'` is  
set. {only with the +eval feature}

#### InsertEnter

InsertEnter

Just before starting Insert mode. Also for  
Replace mode and Virtual Replace mode. The  
`v:insertmode` variable indicates the mode.  
Be careful not to do anything else that the  
user does not expect.  
The cursor is restored afterwards. If you do  
not want that set `v:char` to a non-empty  
string.

#### InsertLeavePre

InsertLeavePre

Just before leaving Insert mode. Also when  
using `CTRL-O i_CTRL-O` . Be careful not to  
change mode or use `:normal``, it will likely  
cause trouble.

#### InsertLeave

InsertLeave

Just after leaving Insert mode. Also when  
using `CTRL-O i_CTRL-O` . But not for `i_CTRL-C` .

#### KeyInputPre

KeyInputPre

Just before a key is processed after mappings  
have been applied. The pattern is matched  
against a string that indicates the current  
mode, which is the same as what is returned by  
``mode(1)``.

The `v:char` variable indicates the key typed  
and can be changed during the event to process  
a different key. When `v:char` is not a  
single character or a special key, the first  
character is used.

The following values of `v:event` are set:

<code>typed</code>	The key is typed or not.
<code>typedchar</code>	The (actual) typed key since the last <code>KeyInputPre</code> call.

**Note:** "typedchar" may be empty if successive  
`KeyInputPre` autocmds are processed.

It is not allowed to change the text  
`textlock` or the current mode.

{only with the +eval feature}

#### MenuPopup

MenuPopup

Just before showing the popup menu (under the  
right mouse button). Useful for adjusting the  
menu for what is under the cursor or mouse  
pointer.

The pattern is matched against one or two  
characters representing the mode:

<code>n</code>	Normal
<code>v</code>	Visual
<code>o</code>	Operator-pending
<code>i</code>	Insert
<code>c</code>	Command line
<code>t\</code>	Terminal

#### ModeChanged

## ModeChanged

After changing the mode. The pattern is matched against `'old_mode:new_mode'`, for example match against `':c*` to simulate `CmdlineEnter` .

The following values of `v:event` are set:

<code>old_mode</code>	The mode before it changed.
<code>new_mode</code>	The new mode as also returned by <code>mode()</code> called with a non-zero argument.

When `ModeChanged` is triggered, `old_mode` will have the value of `new_mode` when the event was last triggered.

This will be triggered on every minor mode change.

Usage example to use relative line numbers when entering Visual mode:

```
:au ModeChanged [vV\x16]*:* let &l:rnu = mode() =~# '^[\v\x16]'
:au ModeChanged *:[vV\x16]* let &l:rnu = mode() =~# '^[\v\x16]'
:au WinEnter,WinLeave * let &l:rnu = mode() =~# '^[\v\x16]'
```

## OptionSet

## OptionSet

After setting an option. The pattern is matched against the long option name. `<amatch>` indicates what option has been set.

`v:option_type` indicates whether it's global or local scoped.

`v:option_command` indicates what type of set/let command was used (follow the tag to see the table).

`v:option_new` indicates the newly set value.

`v:option_oldlocal` has the old local value.

`v:option_oldglobal` has the old global value.

`v:option_old` indicates the old option value.

`v:option_oldlocal` is only set when `:set` or `:setlocal` or a `modeline` was used to set the option. Similarly `v:option_oldglobal` is only set when `:set` or `:setglobal` was used.

This does not set `<abuf>` , you could use `bufnr()` .

**Note** that when setting a `global-local` string option with `:set` , then `v:option_old` is the old global value. However, for all other kinds of options (local string options, global-local number options, ...) it is the old local value.

`OptionSet` is not triggered on startup and for the `'key'` option for obvious reasons.

Usage example: Check for the existence of the directory in the `'backupdir'` and `'undodir'`

options, create the directory if it doesn't exist yet.

**Note:** It's a bad idea to reset an option during this autocommand, this may break a plugin. You can always use ``:noa`` to prevent triggering this autocommand.

When using `:set` in the autocommand the event is not triggered again.

QuickFixCmdPre	<p style="text-align: right;"><b>QuickFixCmdPre</b></p> <p>Before a quickfix command is run ( <code>:make</code> , <code>:lmake</code> , <code>:grep</code> , <code>:lgrep</code> , <code>:grepadd</code> , <code>:lgrepadd</code> , <code>:vimgrep</code> , <code>:lvimgrep</code> , <code>:vimgrepadd</code> , <code>:lvimgrepadd</code> , <code>:cscope</code> , <code>:cfile</code> , <code>:cgetfile</code> , <code>:caddfile</code> , <code>:lfile</code> , <code>:lgetfile</code> , <code>:laddfile</code> , <code>:helpgrep</code> , <code>:lhelpgrep</code> , <code>:cexpr</code> , <code>:cgetexpr</code> , <code>:caddexpr</code> , <code>:cbuffer</code> , <code>:cgetbuffer</code> , <code>:caddbuffer</code> ).</p> <p>The pattern is matched against the command being run. When <code>:grep</code> is used but <code>'grepvprg'</code> is set to "internal" it still matches "grep". This command cannot be used to set the <code>'makeprg'</code> and <code>'grepvprg'</code> variables.</p> <p>If this command causes an error, the quickfix command is not executed.</p>
QuickFixCmdPost	<p style="text-align: right;"><b>QuickFixCmdPost</b></p> <p>Like QuickFixCmdPre, but after a quickfix command is run, before jumping to the first location. For <code>:cfile</code> and <code>:lfile</code> commands it is run after the error file is read and before moving to the first error. See <a href="#">QuickFixCmdPost-example</a> .</p>
QuitPre	<p style="text-align: right;"><b>QuitPre</b></p> <p>When using <code>`:quit`</code> , <code>`:wq`</code> or <code>`:qall`</code> , before deciding whether it closes the current window or quits Vim. For <code>`:wq`</code> the buffer is written before QuitPre is triggered. Can be used to close any non-essential window if the current window is the last ordinary window. Also see <a href="#">ExitPre</a> .</p>
RemoteReply	<p style="text-align: right;"><b>RemoteReply</b></p> <p>When a reply from a Vim that functions as server was received <code>server2client()</code> . The pattern is matched against the <code>{serverid}</code> . <code>&lt;amatch&gt;</code> is equal to the <code>{serverid}</code> from which the reply was sent, and <code>&lt;afile&gt;</code> is the actual reply string.</p> <p><b>Note</b> that even if an autocommand is defined, the reply should be read with <code>remote_read()</code> to consume it.</p>
SafeState	<p style="text-align: right;"><b>SafeState</b></p> <p>When nothing is pending, going to wait for the</p>

user to type a character.  
This will not be triggered when:

- an operator is pending
- a register was entered with "r
- halfway executing a command
- executing a mapping
- there is typeahead
- Insert mode completion is active
- Command line completion is active

You can use ``mode()`` to find out what state Vim is in. That may be:

- Visual mode
- Normal mode
- Insert mode
- Command-line mode

Depending on what you want to do, you may also check more with ``state()``, e.g. whether the screen was scrolled for messages.

#### SafeStateAgain

SafeStateAgain

Like SafeState but after processing any messages and invoking callbacks. This may be triggered often, don't do something that takes time.

#### SessionLoadPost

SessionLoadPost

After loading the session file created using the `:mksession` command.

#### SessionWritePost

SessionWritePost

After writing a session file by calling the `:mksession` command.

#### ShellCmdPost

ShellCmdPost

After executing a shell command with `!:cmd`, `:shell`, `:make` and `:grep`. Can be used to check for any changed files.

#### ShellFilterPost

ShellFilterPost

After executing a shell command with `:{range}!cmd`, `:w !cmd` or `:r !cmd`. Can be used to check for any changed files.

#### SourcePre

SourcePre

Before sourcing a Vim script. `:source <file>` is the name of the file being sourced.

#### SourcePost

SourcePost

After sourcing a Vim script. `:source <file>` is the name of the file being sourced. Not triggered when sourcing was interrupted. Also triggered after a SourceCmd autocommand was triggered.

#### SourceCmd

SourceCmd

When sourcing a Vim script. `:source <file>` is the name of the file being sourced. The autocommand must source this file.  
`Cmd-event`

#### SpellFileMissing

SpellFileMissing

When trying to load a spell checking file and

it can't be found. The pattern is matched against the language. `<amatch>` is the language, **'encoding'** also matters. See [spell-SpellFileMissing](#) .

	<b>StdinReadPost</b>	After reading from the stdin into the buffer, before executing the modelines. Only used when the "-" argument was used when Vim was started -- .
	<b>StdinReadPre</b>	Before reading from stdin into the buffer. Only used when the "-" argument was used when Vim was started -- .
	<b>SwapExists</b>	<p>Detected an existing swap file when starting to edit a file. Only when it is possible to select a way to handle the situation, when Vim would ask the user what to do.</p> <p>The <code>v:swapname</code> variable holds the name of the swap file found, <code>&lt;afile&gt;</code> the file being edited. <code>v:swapcommand</code> may contain a command to be executed in the opened file.</p> <p>The commands should set the <code>v:swapchoice</code> variable to a string with one character to tell Vim what should be done next:</p> <ul style="list-style-type: none"><li>'o' open read-only</li><li>'e' edit the file anyway</li><li>'r' recover</li><li>'d' delete the swap file</li><li>'q' quit, don't edit the file</li><li>'a' abort, like hitting <b>CTRL-C</b></li></ul> <p>When set to an empty string the user will be asked, as if there was no SwapExists autocmd.</p> <p><b>E812</b></p> <p>It is not allowed to change to another buffer, change a buffer name or change directory here.</p> <p>{only available with the +eval feature}</p>
	<b>Syntax</b>	<p>When the <b>'syntax'</b> option has been set. The pattern is matched against the syntax name. <code>&lt;afile&gt;</code> can be used for the name of the file where this option was set, and <code>&lt;amatch&gt;</code> for the new value of <b>'syntax'</b>.</p> <p>See <a href="#">:syn-on</a> .</p>
	<b>TabClosed</b>	After closing a tab page.
	<b>TabClosedPre</b>	Before closing a tab page. The window layout is locked, thus opening and closing of windows is prohibited.
	<b>TabEnter</b>	Just after entering a tab page. <code>tab-page</code> After triggering the WinEnter and before

	triggering the BufEnter event.
	<b>TabLeave</b>
TabLeave	Just before leaving a tab page. <code>tab-page</code> A WinLeave event will have been triggered first.
	<b>TabNew</b>
TabNew	When a tab page was created. <code>tab-page</code> A WinEnter event will have been triggered first, TabEnter follows.
	<b>TermChanged</b>
TermChanged	After the value of <code>'term'</code> has changed. Useful for re-loading the syntax file to update the colors, fonts and other terminal-dependent settings. Executed for all loaded buffers.
	<b>TerminalOpen</b>
TerminalOpen	Just after a terminal buffer was created, with <code>:terminal</code> or <code>term_start()</code> . This event is triggered even if the buffer is created without a window, with the <code>++hidden</code> option.
	<b>TerminalWinOpen</b>
TerminalWinOpen	Just after a terminal buffer was created, with <code>:terminal</code> or <code>term_start()</code> . This event is triggered only if the buffer is created with a window. Can be used to set window local options for the terminal window.
	<b>TermResponse</b>
TermResponse	After the response to <code>t_RV</code> is received from the terminal. The value of <code>v:termresponse</code> can be used to do things depending on the terminal version. This is used in <code>defaults.vim</code> to detect putty terminal and set a dark background:
	<pre>au TermResponse * \ if v:termresponse == "\e[&gt;0;136;0c" \   set bg=dark \ endif</pre>
	<b>Note:</b> that this event may be triggered halfway executing another event, especially if file I/O, a shell command or anything else that takes time is involved.
	<b>TermResponseAll</b>
TermResponseAll	After the response to <code>t_RV</code> , <code>t_RC</code> , <code>t_RS</code> , <code>t_RB</code> , <code>t_RF</code> , or <code>t_u7</code> are received from the terminal. The value of <code>v:termresponse</code> , <code>v:termblinkresp</code> , <code>v:termstyleresp</code> , <code>v:termrbgresp</code> , <code>v:termrfgresp</code> , and <code>v:termu7resp</code> , correspondingly, can be used. <code>&lt;amatch&gt;</code> will be set to any of: "version", "cursorblink", "cursorshape", "background",

```
"foreground",
"ambiguouswidth"
```

Note that this event may be triggered halfway executing another event, especially if file I/O, a shell command or anything else that takes time is involved.

TextChanged	<p style="text-align: center;"><b>TextChanged</b></p> <p>After a change was made to the text in the current buffer in Normal mode. That is after <code>b:changedtick</code> has changed (also when that happened before the TextChanged autocmd was defined).</p> <p>Not triggered when there is typeahead or when an operator is pending.</p> <p><b>Note:</b> This can not be skipped with <code>`:noautocmd`</code>.</p> <p>Careful: This is triggered very often, don't do anything that the user does not expect or that is slow.</p>												
TextChangedI	<p style="text-align: center;"><b>TextChangedI</b></p> <p>After a change was made to the text in the current buffer in Insert mode.</p> <p>Not triggered when the popup menu is visible. Otherwise the same as TextChanged.</p>												
TextChangedP	<p style="text-align: center;"><b>TextChangedP</b></p> <p>After a change was made to the text in the current buffer in Insert mode, only when the popup menu is visible. Otherwise the same as TextChanged.</p>												
TextChangedT	<p style="text-align: center;"><b>TextChangedT</b></p> <p>After a change was made to the text in the current buffer in Terminal mode.</p> <p>Otherwise the same as TextChanged.</p>												
TextYankPost	<p style="text-align: center;"><b>TextYankPost</b></p> <p>After text has been yanked or deleted in the current buffer. The following values of <code>v:event</code> can be used to determine the operation that triggered this autocmd:</p> <table><tr><td>inclusive</td><td>TRUE if the motion is <code>inclusive</code> else the motion is <code>exclusive</code> .</td></tr><tr><td>operator</td><td>The operation performed.</td></tr><tr><td>regcontents</td><td>Text that was stored in the register, as a list of lines, like with: <code>getreg(r, 1, 1)</code></td></tr><tr><td>regname</td><td>Name of the register or empty string for the unnamed register, see <code>registers</code> .</td></tr><tr><td>regtype</td><td>Type of the register, see <code>getregtype()</code> .</td></tr><tr><td>visual</td><td>True if the operation is performed on a <code>Visual</code> area.</td></tr></table> <p>Not triggered when <code>quote_</code> is used nor when</p>	inclusive	TRUE if the motion is <code>inclusive</code> else the motion is <code>exclusive</code> .	operator	The operation performed.	regcontents	Text that was stored in the register, as a list of lines, like with: <code>getreg(r, 1, 1)</code>	regname	Name of the register or empty string for the unnamed register, see <code>registers</code> .	regtype	Type of the register, see <code>getregtype()</code> .	visual	True if the operation is performed on a <code>Visual</code> area.
inclusive	TRUE if the motion is <code>inclusive</code> else the motion is <code>exclusive</code> .												
operator	The operation performed.												
regcontents	Text that was stored in the register, as a list of lines, like with: <code>getreg(r, 1, 1)</code>												
regname	Name of the register or empty string for the unnamed register, see <code>registers</code> .												
regtype	Type of the register, see <code>getregtype()</code> .												
visual	True if the operation is performed on a <code>Visual</code> area.												

called recursively.  
It is not allowed to change the buffer text, see `textlock` . `E1064`  
Also triggered indirectly when Vim tries to become owner of the Visual selection because of setting "autoselect" for '`guioptions`' or '`clipboard`'.  
{only when compiled with the +eval feature}

User	<p style="text-align: center;"><code>User</code></p> <p>Never executed automatically. To be used for autocommands that are only executed with <code>":doautocmd"</code>.</p> <p><b>Note</b> that when <code>`:doautocmd User MyEvent`</code> is used while there are no matching autocommands, you will get an error. If you don't want that, either check whether an autocommand is defined using <code>`exists('#User#MyEvent')`</code> or define a dummy autocommand yourself.</p> <p>Example:</p> <pre>if exists('#User#MyEvent')   doautocmd User MyEvent endif</pre>
SigUSR1	<p style="text-align: center;"><code>SigUSR1</code></p> <p>After the SIGUSR1 signal has been detected. Could be used if other ways of notifying Vim are not feasible. E.g. to check for the result of a build that takes a long time, or when a motion sensor is triggered. {only on Unix}</p>
UserGettingBored	<p style="text-align: center;"><code>UserGettingBored</code></p> <p>When the user presses the same key 42 times. Just kidding! :-)</p>
VimEnter	<p style="text-align: center;"><code>VimEnter</code></p> <p>After doing all the startup stuff, including loading <code>.vimrc</code> files, executing the <code>"-c cmd"</code> arguments, creating all windows and loading the buffers in them. Just before this event is triggered the <code>v:vim_did_enter</code> variable is set, so that you can do:</p> <pre>if v:vim_did_enter   call s:init() else   au VimEnter * call s:init() endif</pre>
VimLeave	<p style="text-align: center;"><code>VimLeave</code></p> <p>Before exiting Vim, just after writing the <code>.viminfo</code> file. Executed only once, like <code>VimLeavePre</code>. To detect an abnormal exit use <code>v:dying</code> . When <code>v:dying</code> is 2 or more this event is not</p>

	<p>triggered. To get the exit code use <code>v:exiting</code> .</p>
VimLeavePre	<p><code>VimLeavePre</code> Before exiting Vim, just before writing the <code>.viminfo</code> file. This is executed only once, if there is a match with the name of what happens to be the current buffer when exiting. Mostly useful with a "*" pattern.</p> <p><code>:autocmd VimLeavePre * call CleanupStuff()</code></p> <p>To detect an abnormal exit use <code>v:dying</code> . When <code>v:dying</code> is 2 or more this event is not triggered. To get the exit code use <code>v:exiting</code> .</p>
VimResized	<p><code>VimResized</code> After the Vim window was resized, thus <code>'lines'</code> and/or <code>'columns'</code> changed. Not when starting up though.</p>
VimResume	<p><code>VimResume</code> When the Vim instance is resumed after being suspended and <code>VimSuspend</code> was triggered. Useful for triggering <code>:checktime</code> and ensure the buffers content did not change while Vim was suspended:</p> <p><code>:autocmd VimResume * checktime</code></p>
VimSuspend	<p><code>VimSuspend</code> When the Vim instance is suspended. Only when <b>CTRL-Z</b> was typed inside Vim, or when the SIGTSTP signal was sent to Vim, but not for SIGSTOP.</p>
WinClosed	<p><code>WinClosed</code> When closing a window, just before it is removed from the window layout. The pattern is matched against the <code>window-ID</code> . Both <code>&lt;amatch&gt;</code> and <code>&lt;afile&gt;</code> are set to the <code>window-ID</code> . Non-recursive (event cannot trigger itself).</p>
WinEnter	<p><code>WinEnter</code> After entering another window. Not done for the first window, when Vim has just started. Useful for setting the window height. If the window is for another buffer, Vim executes the BufEnter autocommands after the WinEnter autocommands. <b>Note:</b> For split and tabpage commands the WinEnter event is triggered after the split or tab command but before the file is loaded.</p>
WinLeave	<p><code>WinLeave</code> Before leaving a window. If the window to be entered next is for a different buffer, Vim executes the BufLeave autocommands before the WinLeave autocommands (but not for <code>:"new"</code>). Not used for <code>:"qa"</code> or <code>:"q"</code> when exiting Vim.</p>
	<p><code>WinNewPre</code></p>

WinNewPre	<p>Before creating a new window. Triggered before commands that modify window layout by creating a split.</p> <p>Not done when creating tab pages and for the first window, as the window structure is not initialized yet and so is generally not safe. It is not allowed to modify window layout while executing commands for the WinNewPre event.</p> <p>Most useful to store current window layout and compare it with the new layout after the Window has been created.</p>
WinNew	<p style="text-align: right;"><b>WinNew</b></p> <p>When a new window was created. Not done for the first window, when Vim has just started. Before a WinEnter event.</p>
WinScrolled	<p style="text-align: right;"><b>WinScrolled</b></p> <p>After any window in the current tab page scrolled the text (horizontally or vertically) or changed width or height. See <a href="#">win-scrolled-resized</a> .</p> <p>The pattern is matched against the <a href="#">window-ID</a> of the first window that scrolled or resized. Both <a href="#">&lt;amatch&gt;</a> and <a href="#">&lt;afile&gt;</a> are set to the <a href="#">window-ID</a> .</p> <p><a href="#">v:event</a> is set with information about size and scroll changes. <a href="#">WinScrolled-event</a></p> <p>Only starts triggering after startup finished and the first screen redraw was done. Does not trigger when defining the first WinScrolled or WinResized event, but may trigger when adding more.</p> <p>Non-recursive: the event will not trigger while executing commands for the WinScrolled event. However, if the command causes a window to scroll or change size, then another WinScrolled event will be triggered later.</p>
WinResized	<p style="text-align: right;"><b>WinResized</b></p> <p>After a window in the current tab page changed width or height. See <a href="#">win-scrolled-resized</a> .</p> <p><a href="#">v:event</a> is set with information about size changes. <a href="#">WinResized-event</a></p> <p>Same behavior as <a href="#">WinScrolled</a> for the</p>

pattern, triggering and recursiveness.

---

## 6. Patterns

autocmd-patterns {aupat}

The {aupat} argument of `:autocmd` can be a comma-separated list. This works as if the command was given with each pattern separately. Thus this command:

```
:autocmd BufRead *.txt,*.info set et
```

Is equivalent to:

```
:autocmd BufRead *.txt set et
:autocmd BufRead *.info set et
```

The file pattern {aupat} is tested for a match against the file name in one of two ways:

1. When there is no '/' in the pattern, Vim checks for a match against only the tail part of the file name (without its leading directory path).
2. When there is a '/' in the pattern, Vim checks for a match against both the short file name (as you typed it) and the full file name (after expanding it to a full path and resolving symbolic links).

The special pattern <buffer> or <buffer=N> is used for buffer-local autocommands `autocmd-buflocal`. This pattern is not matched against the name of a buffer.

Examples:

```
:autocmd BufRead *.txt set et
```

Set the **'et'** option for all text files.

```
:autocmd BufRead /vim/src/*.c set cindent
```

Set the **'cindent'** option for C files in the /vim/src directory.

```
:autocmd BufRead /tmp/*.c set ts=5
```

If you have a link from "/tmp/test.c" to "/home/nobody/vim/src/test.c", and you start editing "/tmp/test.c", this autocommand will match.

**Note:** To match part of a path, but not from the root directory, use a '\*' as the first character. Example:

```
:autocmd BufRead */doc/*.txt set tw=78
```

This autocommand will for example be executed for "/tmp/doc/xx.txt" and "/usr/home/piet/doc/yy.txt". The number of directories does not matter here.

The file name that the pattern is matched against is after expanding wildcards. Thus if you issue this command:

```
:e $ROOTDIR/main.$EXT
```

The argument is first expanded to:

```
/usr/root/main.py
```

Before it's matched with the pattern of the autocommand. Careful with this when using events like FileReadCmd, the value of <amatch> may not be what you expect.

Environment variables can be used in a pattern:

```
:autocmd BufRead $VIMRUNTIME/doc/*.txt set expandtab
```

And ~ can be used for the home directory (if \$HOME is defined):

```
:autocmd BufWritePost ~/.vimrc so ~/.vimrc
:autocmd BufRead ~archive/* set readonly
```

The environment variable is expanded when the autocommand is defined, not when the autocommand is executed. This is different from the command!

### file-pattern

The pattern is interpreted like mostly used in file names:

```
* matches any sequence of characters; Unusual: includes path
 separators
? matches any single character
\? matches a '?'
. matches a '.'
~ matches a '~'
, separates patterns
\, matches a ','
{ } like \(\) in a pattern
, inside { }: like \| in a pattern
\} literal }
\{ literal {
\\{n,m} like \{n,m} in a pattern
\ special meaning like in a pattern
[ch] matches 'c' or 'h'
[^ch] match any character but 'c' and 'h'
```

**Note** that for all systems the '/' character is used for path separator (even for MS-Windows). This was done because the backslash is difficult to use in a pattern and to make the autocommands portable across different systems.

It is possible to use `pattern` items, but they may not work as expected, because of the translation done for the above.

### autocmd-changes

Matching with the pattern is done when an event is triggered. Changing the buffer name in one of the autocommands, or even deleting the buffer, does not change which autocommands will be executed. Example:

```
au BufEnter *.foo bdel
au BufEnter *.foo set modified
```

This will delete the current buffer and then set **'modified'** in what has become the current buffer instead. Vim doesn't take into account that "\*.foo" doesn't match with that buffer name. It matches "\*.foo" with the name of the buffer at the moment the event was triggered.

However, buffer-local autocommands will not be executed for a buffer that has been wiped out with `:bwipe`. After deleting the buffer with `:bdel` the buffer actually still exists (it becomes unlisted), thus the autocommands are still executed.

```
=====
7. Buffer-local autocommands autocmd-buflocal autocmd-buffer-local
 <buffer=N> <buffer=abuf> E680
```

Buffer-local autocommands are attached to a specific buffer. They are useful if the buffer does not have a name and when the name does not match a specific pattern. But it also means they must be explicitly added to each buffer.

Instead of a pattern buffer-local autocommands use one of these forms:

```
<buffer> current buffer
<buffer=99> buffer number 99
<buffer=abuf> using <abuf> (only when executing autocommands)
 <abuf>
```

Examples:

```
:au CursorHold <buffer> echo 'hold'
:au CursorHold <buffer=33> echo 'hold'
:au BufNewFile * au CursorHold <buffer=abuf> echo 'hold'
```

All the commands for autocommands also work with buffer-local autocommands, simply use the special string instead of the pattern. Examples:

```
:au! * <buffer> " remove buffer-local autocommands for
 " current buffer
:au! * <buffer=33> " remove buffer-local autocommands for
 " buffer #33
:bufdo :au! CursorHold <buffer> " remove autocmd for given event for all
 " buffers
:au * <buffer> " list buffer-local autocommands for
 " current buffer
```

**Note** that when an autocommand is defined for the current buffer, it is stored with the buffer number. Thus it uses the form "`<buffer=12>`", where 12 is the number of the current buffer. You will see this when listing autocommands, for example.

To test for presence of buffer-local autocommands use the `exists()` function as follows:

```
:if exists("#CursorHold#<buffer=12>") | ... | endif
:if exists("#CursorHold#<buffer>") | ... | endif " for current buffer
```

When a buffer is wiped out its buffer-local autocommands are also gone, of course. **Note** that when deleting a buffer, e.g., with `:bdel`, it is only unlisted, the autocommands are still present. In order to see the removal of buffer-local autocommands:

```
:set verbose=6
```

It is not possible to define buffer-local autocommands for a non-existent buffer.

---

## 8. Groups autocmd-groups

Autocommands can be put together in a group. This is useful for removing or executing a group of autocommands. For example, all the autocommands for syntax highlighting are put in the "highlight" group, to be able to execute `:doautoall highlight BufRead` when the GUI starts.

When no specific group is selected, Vim uses the default group. The default

group does not have a name. You cannot execute the autocommands from the default group separately; you can execute them only by executing autocommands for all groups.

Normally, when executing autocommands automatically, Vim uses the autocommands for all groups. The group only matters when executing autocommands with `":doautocmd"` or `":doautoall"`, or when defining or deleting autocommands.

The group name can contain any characters except white space. The group name "end" is reserved (also in uppercase).

The group name is case sensitive. **Note** that this is different from the event name!

```
 :aug :augroup
:aug[roup] {name} Define the autocmd group name for the
 following ":autocmd" commands. The name "end"
 or "END" selects the default group.
 To avoid confusion, the name should be
 different from existing {event} names, as this
 most likely will not do what you intended.
```

```
 :augroup-delete E367 W19 E936
:aug[roup]! {name} Delete the autocmd group {name}. Don't use
 this if there is still an autocommand using
 this group! You will get a warning if doing
 it anyway. When the group is the current
 group you will get error E936.
```

To enter autocommands for a specific group, use this method:

1. Select the group with `":augroup {name}"`.
2. Delete any old autocommands with `":au!"`.
3. Define the autocommands.
4. Go back to the default group with `"augroup END"`.

Example:

```
:augroup uncompress
: au!
: au BufEnter *.gz %!gunzip
:augroup END
```

This prevents having the autocommands defined twice (e.g., after sourcing the `.vimrc` file again).

### FileExplorer

There is one group that is recognized by Vim: FileExplorer. If this group exists Vim assumes that editing a directory is possible and will trigger a plugin that lists the files in that directory. This is used by the `netrw` plugin. This allows you to do:

`browse edit`

```
=====
9. Executing autocommands autocmd-execute
```

Vim can also execute Autocommands non-automatically. This is useful if you have changed autocommands, or when Vim has executed the wrong autocommands (e.g., the file pattern match was wrong).

**Note** that the **'eventignore'** option applies here too. Events listed in this option will not cause any commands to be executed.

```
 :do :doau :doaut :doautcmd E217
:do[autocmd] [<nomodeline>] [group] {event} [fname]
 Apply the autocommands matching [fname] (default:
 current file name) for {event} to the current buffer.
 You can use this when the current file name does not
 match the right pattern, after changing settings, or
 to execute autocommands for a certain event.
 It's possible to use this inside an autocommand too,
 so you can base the autocommands for one extension on
 another extension. Example:
 :au BufEnter *.cpp so ~/.vimrc_cpp
 :au BufEnter *.cpp doau BufEnter x.c
Be careful to avoid endless loops. See
 autocmd-nested .
```

When the [group] argument is not given, Vim executes the autocommands for all groups. When the [group] argument is included, Vim executes only the matching autocommands for that group. **Note:** if you use an undefined group name, Vim gives you an error message.

After applying the autocommands the modelines are processed, so that their settings overrule the settings from autocommands, like what happens when editing a file. This is skipped when the <nomodeline> argument is present. You probably want to use <nomodeline> for events that are not used when loading a buffer, such as **User** . Processing modelines is also skipped when no matching autocommands were executed.

```
 :doautoa :doautoall
:doautoa[ll] [<nomodeline>] [group] {event} [fname]
 Like ":doautocmd", but apply the autocommands to each
 loaded buffer. The current buffer is done last.
```

**Note** that [fname] is used to select the autocommands, not the buffers to which they are applied. Example:

```
 augroup mine
 autocmd!
 autocmd FileType * echo expand('<amatch>')
 augroup END
 doautoall mine FileType Loaded-Buffer
Sourcing this script, you'll see as many
"Loaded-Buffer" echoed as there are loaded buffers.
```

Careful: Don't use this for autocommands that delete a

buffer, change to another buffer or change the contents of a buffer; the result is unpredictable. This command is intended for autocommands that set options, change highlighting, and things like that.

---

## 10. Using autocommands

autocmd-use

For WRITING FILES there are four possible sets of events. Vim uses only one of these sets for a write command:

BufWriteCmd	BufWritePre	BufWritePost	writing the whole buffer
	FilterWritePre	FilterWritePost	writing to filter temp file
FileAppendCmd	FileAppendPre	FileAppendPost	appending to a file
FileWriteCmd	FileWritePre	FileWritePost	any other file write

When there is a matching "\*Cmd" autocommand, it is assumed it will do the writing. No further writing is done and the other events are not triggered.

Cmd-event

**Note** that the \*WritePost commands should undo any changes to the buffer that were caused by the \*WritePre commands; otherwise, writing the file will have the side effect of changing the buffer.

Before executing the autocommands, the buffer from which the lines are to be written temporarily becomes the current buffer. Unless the autocommands change the current buffer or delete the previously current buffer, the previously current buffer is made the current buffer again.

The \*WritePre and \*AppendPre autocommands must not delete the buffer from which the lines are to be written.

The '[' and ']' marks have a special position:

- Before the \*ReadPre event the '[' mark is set to the line just above where the new lines will be inserted.
- Before the \*ReadPost event the '[' mark is set to the first line that was just read, the ']' mark to the last line.
- Before executing the \*WriteCmd, \*WritePre and \*AppendPre autocommands the '[' mark is set to the first line that will be written, the ']' mark to the last line.

Careful: '[' and ']' change when using commands that change the buffer.

In commands which expect a file name, you can use "<file>" for the file name that is being read :<file> (you can also use "%" for the current file name). "<abuf>" can be used for the buffer number of the currently effective buffer. This also works for buffers that don't have a name. But it doesn't work for files without a buffer (e.g., with ":r file").

gzip-example

Examples for reading and writing compressed files:

```
:augroup gzip
: autocmd!
: autocmd BufReadPre,FileReadPre *.gz set bin
: autocmd BufReadPost,FileReadPost *.gz '[,']!gunzip
```

```

: autocmd BufReadPost,FileReadPost *.gz set nobin
: autocmd BufReadPost,FileReadPost *.gz execute ":doautocmd BufReadPost " .. expand("%
: autocmd BufWritePost,FileWritePost *.gz !mv <afile> <afile>:r
: autocmd BufWritePost,FileWritePost *.gz !gzip <afile>:r

: autocmd FileAppendPre *.gz !gunzip <afile>
: autocmd FileAppendPre *.gz !mv <afile>:r <afile>
: autocmd FileAppendPost *.gz !mv <afile> <afile>:r
: autocmd FileAppendPost *.gz !gzip <afile>:r
:augroup END

```

The "gzip" group is used to be able to delete any existing autocommands with ":autocmd!", for when the file is sourced twice.

("<afile>:r" is the file name without the extension, see [:\\_%:](#) )

The commands executed for the BufNewFile, BufRead/BufReadPost, BufWritePost, FileAppendPost and VimLeave events do not set or reset the changed flag of the buffer. When you decompress the buffer with the BufReadPost autocommands, you can still exit with ":q". When you use ":undo" in BufWritePost to undo the changes made by BufWritePre commands, you can still do ":q" (this also makes "ZZ" work). If you do want the buffer to be marked as modified, set the **'modified'** option.

To execute Normal mode commands from an autocommand, use the ":normal" command. Use with care! If the Normal mode command is not finished, the user needs to type characters (e.g., after ":normal m" you need to type a mark name).

If you want the buffer to be unmodified after changing it, reset the **'modified'** option. This makes it possible to exit the buffer with ":q" instead of ":q!".

#### autocmd-nested E218

By default, autocommands do not nest. For example, if you use ":e" or ":w" in an autocommand, Vim does not execute the BufRead and BufWrite autocommands for those commands. If you do want this, use the "nested" flag for those commands in which you want nesting. For example:

```
:autocmd FileChangedShell *.c ++nested e!
```

The nesting is limited to 10 levels to get out of recursive loops.

It's possible to use the ":au" command in an autocommand. This can be a self-modifying command! This can be useful for an autocommand that should execute only once.

If you want to skip autocommands for one command, use the [:noautocmd](#) command modifier or the **'eventignore'** option.

**Note:** When reading a file (with ":read file" or with a filter command) and the last line in the file does not have an `<EOL>`, Vim remembers this. At the next write (with ":write file" or with a filter command), if the same line is written again as the last line in a file AND **'binary'** is set, Vim does not supply an `<EOL>`. This makes a filter command on the just read lines write the same file as was read, and makes a write command on just filtered lines write

the same file as was read from the filter. For example, another way to write a compressed file:

```
:autocmd FileWritePre *.gz set bin|'|,']!gzip
:autocmd FileWritePost *.gz undo|set nobin
```

autocommand-pattern

You can specify multiple patterns, separated by commas. Here are some examples:

```
:autocmd BufRead * set tw=79 nocin ic infercase fo=2croq
:autocmd BufRead .letter set tw=72 fo=2tcrg
:autocmd BufEnter .letter set dict=/usr/lib/dict/words
:autocmd BufLeave .letter set dict=
:autocmd BufRead,BufNewFile *.c,*.h set tw=0 cin noic
:autocmd BufEnter *.c,*.h abbr FOR for (i = 0; i < 3; ++i)<CR>{<CR>}<Esc>O
:autocmd BufLeave *.c,*.h unabbr FOR
```

For makefiles (makefile, Makefile, imakefile, makefile.unix, etc.):

```
:autocmd BufEnter ?akefile* set include=^s\=include
:autocmd BufLeave ?akefile* set include&
```

To always start editing C files at the first function:

```
:autocmd BufRead *.c,*.h 1;/^{
```

Without the "1;" above, the search would start from wherever the file was entered, rather than from the start of the file.

skeleton template

To read a skeleton (template) file when opening a new file:

```
:autocmd BufNewFile *.c 0r ~/vim/skeleton.c
:autocmd BufNewFile *.h 0r ~/vim/skeleton.h
:autocmd BufNewFile *.java 0r ~/vim/skeleton.java
```

To insert the current date and time in a \*.html file when writing it:

```
:autocmd BufWritePre,FileWritePre *.html ks|call LastMod()|'s
:fun LastMod()
: if line("$") > 20
: let l = 20
: else
: let l = line("$")
: endif
: exe "1," .. l .. "g/Last modified: /s/Last modified: ./Last modified: " ..
: \ strftime("%Y %b %d")
: endfun
```

You need to have a line "Last modified: <date time>" in the first 20 lines of the file for this to work. Vim replaces <date time> (and anything in the same line after it) with the current date and time. Explanation:

ks mark current position with mark 's'

```
 call LastMod() call the LastMod() function to do the work
 's return the cursor to the old position
```

The LastMod() function checks if the file is shorter than 20 lines, and then uses the ":g" command to find lines that contain "Last modified: ". For those lines the ":s" command is executed to replace the existing date with the current one. The ":execute" command is used to be able to use an expression for the ":g" and ":s" commands. The date is obtained with the strftime() function. You can change its argument to get another date string.

When entering :autocmd on the command-line, completion of events and command names may be done (with <Tab>, CTRL-D, etc.) where appropriate.

Vim executes all matching autocommands in the order that you specify them. It is recommended that your first autocommand be used for all files by using "\*" as the file pattern. This means that you can define defaults you like here for any settings, and if there is another matching autocommand it will override these. But if there is no other matching autocommand, then at least your default settings are recovered (if entering this file from another for which autocommands did match). Note that "\*" will also match files starting with ".", unlike Unix shells.

#### autocmd-searchpat

Autocommands do not change the current search patterns. Vim saves the current search patterns before executing autocommands then restores them after the autocommands finish. This means that autocommands do not affect the strings highlighted with the 'hlsearch' option. Within autocommands, you can still use search patterns normally, e.g., with the "n" command. If you want an autocommand to set the search pattern, such that it is used after the autocommand finishes, use the ":let @/ =" command. The search-highlighting cannot be switched off with ":nohlsearch" in an autocommand. Use the 'h' flag in the 'viminfo' option to disable search-highlighting when starting Vim.

#### Cmd-event

When using one of the "\*Cmd" events, the matching autocommands are expected to do the file reading, writing or sourcing. This can be used when working with a special kind of file, for example on a remote system.

CAREFUL: If you use these events in a wrong way, it may have the effect of making it impossible to read or write the matching files! Make sure you test your autocommands properly. Best is to use a pattern that will never match a normal file name, for example "ftp://\*".

When defining a BufReadCmd it will be difficult for Vim to recover a crashed editing session. When recovering from the original file, Vim reads only those parts of a file that are not found in the swap file. Since that is not possible with a BufReadCmd, use the :preserve command to make sure the original file isn't needed for recovery. You might want to do this only when you expect the file to be modified.

For file read and write commands the v:cmdarg variable holds the "++enc=" and "++ff=" argument that are effective. These should be used for the command that reads/writes the file. The v:cmdbang variable is one when "!" was used, zero otherwise.

See the \$VIMRUNTIME/plugin/netrwPlugin.vim for examples.

---

## 11. Disabling autocommands

autocmd-disable

To disable autocommands for some time use the **'eventignore'** option. **Note** that this may cause unexpected behavior, make sure you restore **'eventignore'** afterwards, using a **:try** block with **:finally** .

To disable autocmds indefinitely in a specific window use the **'eventignorewin'** option. This can only be used to ignore window and buffer related events.

:noautocmd :noa

To disable autocommands for just one command use the **":noautocmd"** command modifier. This will set **'eventignore'** to "all" for the duration of the following command. Example:

```
:noautocmd w fname.gz
```

This will write the file without triggering the autocommands defined by the gzip plugin.

**Note** that some autocommands are not triggered right away, but only later. This specifically applies to **CursorMoved** and **TextChanged** .

VIM REFERENCE MANUAL by Bram Moolenaar

Expression evaluation [expression](#) [expr](#) [E15](#) [eval](#)  
[E1002](#)

Using expressions is introduced in chapter 41 of the user manual [usr\\_41.txt](#) .

**Note:** Expression evaluation can be disabled at compile time. If this has been done, the features in this document are not available. See [+eval](#) and [no-eval-feature](#) .

This file is mainly about the backwards compatible (legacy) Vim script. For specifics of Vim9 script, which can execute much faster, supports type checking and much more, see [vim9.txt](#) . Where the syntax or semantics differ a remark is given.

=====

- 1. Variables [variables](#)
  - 1.1 Variable types
    - [E712](#) [E896](#) [E897](#) [E899](#) [E1098](#)
    - [E1107](#) [E1135](#) [E1138](#)

There are ten types of variables:

		<a href="#">Number</a> <a href="#">Integer</a>
Number	A 32 or 64 bit signed number. <a href="#">expr-number</a>	
	The number of bits is available in <a href="#">v:numbersize</a> .	

Examples: -123 0x10 0177 0o177 0b1011

Float	A floating point number. <a href="#">floating-point-format</a> <a href="#">Float</a> Examples: 123.456 1.15e-6 -1.1e3
String	A NUL terminated string of 8-bit unsigned characters (bytes). <a href="#">expr-string</a> Examples: "ab\txx\\"" 'x-z''a,c'
List	An ordered sequence of items, see <a href="#">List</a> for details. Example: [1, 2, ['a', 'b']]
Dictionary	An associative, unordered array: Each entry has a key and a value. <a href="#">Dictionary</a> Examples: <pre>{'blue': "#0000ff", 'red': "#ff0000"} #{blue: "#0000ff", red: "#ff0000"}</pre>
Funcref	A reference to a function <a href="#">Funcref</a> . Example: function("strlen") It can be bound to a dictionary and arguments, it then works like a Partial. Example: function("Callback", [arg], myDict)
Special	<a href="#">v:false</a> , <a href="#">v:true</a> , <a href="#">v:none</a> and <a href="#">v:null</a> . <a href="#">Special</a>
Job	Used for a job, see <a href="#">job_start()</a> . <a href="#">Job</a> <a href="#">Jobs</a>
Channel	Used for a channel, see <a href="#">ch_open()</a> . <a href="#">Channel</a> <a href="#">Channels</a>
Blob	Binary Large Object. Stores any sequence of bytes. See <a href="#">Blob</a> for details Example: 0zFF00ED015DAF 0z is an empty Blob.

The Number and String types are converted automatically, depending on how they are used.

Conversion from a Number to a String is by making the ASCII representation of the Number. Examples:

```
Number 123 --> String "123"
Number 0 --> String "0"
Number -1 --> String "-1"
```

[octal](#)

Conversion from a String to a Number only happens in legacy Vim script, not in Vim9 script. It is done by converting the first digits to a number.

Hexadecimal "0xf9", Octal "017" or "0o17", and Binary "0b10" numbers are recognized

**NOTE:** when using [Vim9](#) script or [scriptversion-4](#) octal with a leading "0" is not recognized. The 0o notation requires patch 8.2.0886.

If the String doesn't start with digits, the result is zero.

Examples:

```
String "456" --> Number 456
String "6bar" --> Number 6
String "foo" --> Number 0
```

```
String "0xf1" --> Number 241
String "0100" --> Number 64
String "0o100" --> Number 64
String "0b101" --> Number 5
String "-8" --> Number -8
String "+8" --> Number 0
```

To force conversion from String to Number, add zero to it:

```
:echo "0100" + 0
64
```

To avoid a leading zero to cause octal conversion, or for using a different base, use `str2nr()` .

**TRUE FALSE Boolean**

For boolean operators Numbers are used. Zero is FALSE, non-zero is TRUE. You can also use `v:false` and `v:true` , in Vim9 script `false` and `true` . When TRUE is returned from a function it is the Number one, FALSE is the number zero.

Note that in the command:

```
:if "foo"
:" NOT executed
```

"foo" is converted to 0, which means FALSE. If the string starts with a non-zero number it means TRUE:

```
:if "8foo"
:" executed
```

To test for a non-empty string, use `empty()`:

```
:if !empty("foo")
```

**falsy truthy**

An expression can be used as a condition, ignoring the type and only using whether the value is "sort of true" or "sort of false". Falsy is:

```
the number zero
empty string, blob, list or dictionary
```

Other values are truthy. Examples:

```
0 falsy
1 truthy
-1 truthy
0.0 falsy
0.1 truthy
'' falsy
'x' truthy
[] falsy
[0] truthy
{} falsy
#{x: 1} truthy
0z falsy
0z00 truthy
```

**non-zero-arg**

Function arguments often behave slightly different from **TRUE** : If the argument is present and it evaluates to a non-zero Number, `v:true` or a non-empty String, then the value is considered to be TRUE.

Note that " " and "0" are also non-empty strings, thus considered to be TRUE. A List, Dictionary or Float is not a Number or String, thus evaluate to FALSE.

E611 E745 E728 E703 E729 E730 E731 E908 E910  
E913 E974 E975 E976 E1319 E1320 E1321 E1322  
E1323 E1324

List , Dictionary , Funcref , Job , Channel , Blob , Class and object types are not automatically converted.

E805 E806 E808  
When mixing Number and Float the Number is converted to Float. Otherwise there is no automatic conversion of Float. You can use str2float() for String to Float, printf() for Float to String and float2nr() for Float to Number.

E362 E891 E892 E893 E894 E907 E911 E914  
When expecting a Float a Number can also be used, but nothing else.

no-type-checking  
You will not get an error if you try to change the type of a variable.

## 1.2 Function references

E695 E718 E1192  
A Funcref variable is obtained with the function() function, the funcref() function, (in Vim9 script) the name of a function, or created with the lambda expression expr-lambda . It can be used in an expression in the place of a function name, before the parenthesis around the arguments, to invoke the function it refers to. Example in Vim9 script:

```
:var Fn = MyFunc
:echo Fn()
```

Legacy script:

```
:let Fn = function("MyFunc")
:echo Fn()
```

E704 E705 E707  
A Funcref variable must start with a capital, "s:", "w:", "t:" or "b:". You can use "g:" but the following name must still start with a capital. You cannot have both a Funcref variable and a function with the same name.

A special case is defining a function and directly assigning its Funcref to a Dictionary entry. Example:

```
:function dict.init() dict
: let self.val = 0
:endfunction
```

The key of the Dictionary can start with a lower case letter. The actual function name is not used here. Also see numbered-function .

A Funcref can also be used with the :call command:

```
:call Fn()
:call dict.init()
```

The name of the referenced function can be obtained with string() .

```
:let func = string(Fn)
```

You can use `call()` to invoke a Funcref and use a list variable for the arguments:

```
:let r = call(Fn, mylist)
```

### Partial

A Funcref optionally binds a Dictionary and/or arguments. This is also called a Partial. This is created by passing the Dictionary and/or arguments to `function()` or `funcref()`. When calling the function the Dictionary and/or arguments will be passed to the function. Example:

```
let Cb = function('Callback', ['foo'], myDict)
call Cb('bar')
```

This will invoke the function as if using:

```
call myDict.Callback('foo', 'bar')
```

This is very useful when passing a function around, e.g. in the arguments of `ch_open()`.

**Note** that binding a function to a Dictionary also happens when the function is a member of the Dictionary:

```
let myDict.myFunction = MyFunction
call myDict.myFunction()
```

Here `MyFunction()` will get `myDict` passed as "self". This happens when the "myFunction" member is accessed. When making assigning "myFunction" to `otherDict` and calling it, it will be bound to `otherDict`:

```
let otherDict.myFunction = myDict.myFunction
call otherDict.myFunction()
```

Now "self" will be "otherDict". But when the dictionary was bound explicitly this won't happen:

```
let myDict.myFunction = function(MyFunction, myDict)
let otherDict.myFunction = myDict.myFunction
call otherDict.myFunction()
```

Here "self" will be "myDict", because it was bound explicitly.

## 1.3 Lists

[list](#) [List](#) [Lists](#) [E686](#)

A List is an ordered sequence of items. An item can be of any type. Items can be accessed by their index number. Items can be added and removed at any position in the sequence.

### List creation

[E696](#) [E697](#)

A List is created with a comma-separated list of items in square brackets.

Examples:

```
:let mylist = [1, two, 3, "four"]
:let emptylist = []
```

An item can be any expression. Using a List for an item creates a List of Lists:

```
:let nestlist = [[11, 12], [21, 22], [31, 32]]
```

An extra comma after the last item is ignored.

## List index

[list-index](#) E684

An item in the List can be accessed by putting the index in square brackets after the List. Indexes are zero-based, thus the first item has index zero.

```
:let item = mylist[0] " get the first item: 1
:let item = mylist[2] " get the third item: 3
```

When the resulting item is a list this can be repeated:

```
:let item = nestlist[0][1] " get the first list, second item: 12
```

A negative index is counted from the end. Index -1 refers to the last item in the List, -2 to the last but one item, etc.

```
:let last = mylist[-1] " get the last item: "four"
```

To avoid an error for an invalid index use the `get()` function. When an item is not available it returns zero or the default value you specify:

```
:echo get(mylist, idx)
:echo get(mylist, idx, "NONE")
```

## List concatenation

[list-concatenation](#)

Two lists can be concatenated with the "+" operator:

```
:let longlist = mylist + [5, 6]
:let longlist = [5, 6] + mylist
```

To prepend or append an item, turn it into a list by putting [] around it.

A list can be concatenated with another one in-place using `:let+=` or `extend()` :

```
:let mylist += [7, 8]
:call extend(mylist, [7, 8])
```

See [list-modification](#) below for more about changing a list in-place.

## Sublist

[sublist](#)

A part of the List can be obtained by specifying the first and last index, separated by a colon in square brackets:

```
:let shortlist = mylist[2:-1] " get List [3, "four"]
```

Omitting the first index is similar to zero. Omitting the last index is similar to -1.

```

:let endlis = mylist[2:] " from item 2 to the end: [3, "four"]
:let shortlist = mylist[2:2] " List with one item: [3]
:let otherlist = mylist[:] " make a copy of the List

```

Notice that the last index is inclusive. If you prefer using an exclusive index use the `slice()` method.

If the first index is beyond the last item of the List or the second item is before the first item, the result is an empty list. There is no error message.

If the second index is equal to or greater than the length of the list the length minus one is used:

```

:let mylist = [0, 1, 2, 3]
:echo mylist[2:8] " result: [2, 3]

```

**NOTE:** `mylist[s:e]` means using the variable "s:e" as index. Watch out for using a single letter variable before the ":". Insert a space when needed: `mylist[s : e]`.

## List identity

### list-identity

When variable "aa" is a list and you assign it to another variable "bb", both variables refer to the same list. Thus changing the list "aa" will also change "bb":

```

:let aa = [1, 2, 3]
:let bb = aa
:call add(aa, 4)
:echo bb
[1, 2, 3, 4]

```

Making a copy of a list is done with the `copy()` function. Using `[:]` also works, as explained above. This creates a shallow copy of the list: Changing a list item in the list will also change the item in the copied list:

```

:let aa = [[1, 'a'], 2, 3]
:let bb = copy(aa)
:call add(aa, 4)
:let aa[0][1] = 'aaa'
:echo aa
[[1, aaa], 2, 3, 4]
:echo bb
[[1, aaa], 2, 3]

```

To make a completely independent list use `deepcopy()`. This also makes a copy of the values in the list, recursively. Up to a hundred levels deep.

The operator "is" can be used to check if two variables refer to the same List. "isnot" does the opposite. In contrast "==" compares if two lists have the same value.

```

:let alist = [1, 2, 3]
:let blist = [1, 2, 3]
:echo alist is blist

```

0

```
:echo alist == blist
1
```

**Note** about comparing lists: Two lists are considered equal if they have the same length and all items compare equal, as with using "==". There is one exception: When comparing a number with a string they are considered different. There is no automatic type conversion, as with using "==" on variables. Example:

```
echo 4 == "4"
1
echo [4] == ["4"]
0
```

Thus comparing Lists is more strict than comparing numbers and strings. You can compare simple values this way too by putting them in a list:

```
:let a = 5
:let b = "5"
:echo a == b
1
:echo [a] == [b]
0
```

### List unpack

To unpack the items in a list to individual variables, put the variables in square brackets, like list items:

```
:let [var1, var2] = mylist
```

When the number of variables does not match the number of items in the list this produces an error. To handle any extra items from the list append ";" and a variable name:

```
:let [var1, var2; rest] = mylist
```

This works like:

```
:let var1 = mylist[0]
:let var2 = mylist[1]
:let rest = mylist[2:]
```

Except that there is no error if there are only two items. "rest" will be an empty list then.

### List modification

#### list-modification

To change a specific item of a list use `:let` this way:

```
:let list[4] = "four"
:let listlist[0][3] = item
```

To change part of a list you can specify the first and last item to be modified. The value must at least have the number of items in the range:

```
:let list[3:5] = [3, 4, 5]
```

To add items to a List in-place, you can use `:let+=` ( `list-concatenation` ):

```
:let listA = [1, 2]
:let listA += [3, 4]
```

When two variables refer to the same List, changing one List in-place will cause the referenced List to be changed in-place:

```
:let listA = [1, 2]
:let listB = listA
:let listB += [3, 4]
:echo listA
[1, 2, 3, 4]
```

Adding and removing items from a list is done with functions. Here are a few examples:

```
:call insert(list, 'a') " prepend item 'a'
:call insert(list, 'a', 3) " insert item 'a' before list[3]
:call add(list, "new") " append String item
:call add(list, [1, 2]) " append a List as one new item
:call extend(list, [1, 2]) " extend the list with two more items
:let i = remove(list, 3) " remove item 3
:unset list[3] " idem
:let l = remove(list, 3, -1) " remove items 3 to last item
:unset list[3 :] " idem
:call filter(list, 'v:val !~ "x"') " remove items with an 'x'
```

Changing the order of items in a list:

```
:call sort(list) " sort a list alphabetically
:call reverse(list) " reverse the order of items
:call uniq(sort(list)) " sort and remove duplicates
```

## For loop

The `:for` loop executes commands for each item in a List, String or Blob. A variable is set to each item in sequence. Example with a List:

```
:for item in mylist
: call Doit(item)
:endfor
```

This works like:

```
:let index = 0
:while index < len(mylist)
: let item = mylist[index]
: :call Doit(item)
: let index = index + 1
:endwhile
```

If all you want to do is modify each item in the list then the `map()` function will be a simpler method than a for loop.

Just like the `:let` command, `:for` also accepts a list of variables. This requires the argument to be a List of Lists.

```
:for [lnum, col] in [[1, 3], [2, 8], [3, 0]]
: call Doit(lnum, col)
```

```
:endfor
```

This works like a `:let` command is done for each list item. Again, the types must remain the same to avoid an error.

It is also possible to put remaining items in a List variable:

```
:for [i, j; rest] in listlist
: call Doit(i, j)
: if !empty(rest)
: echo "remainder: " .. string(rest)
: endif
:endif
:endif
```

For a Blob one byte at a time is used.

For a String one character, including any composing characters, is used as a String. Example:

```
for c in text
 echo 'This character is ' .. c
endif
```

## List functions

E714

Functions that are useful with a List:

```
:let r = call(funcname, list) " call a function with an argument list
:if empty(list) " check if list is empty
:let l = len(list) " number of items in list
:let big = max(list) " maximum value in list
:let small = min(list) " minimum value in list
:let xs = count(list, 'x') " count nr of times 'x' appears in list
:let i = index(list, 'x') " index of first 'x' in list
:let lines = getline(1, 10) " get ten text lines from buffer
:call append('$', lines) " append text lines in buffer
:let list = split("a b c") " create list from items in a string
:let string = join(list, ', ') " create string from list items
:let s = string(list) " String representation of list
:call map(list, "'>> " .. v:val') " prepend ">> " to each item
```

Don't forget that a combination of features can make things simple. For example, to add up all the numbers in a list:

```
:exe 'let sum = ' .. join(nrlist, '+')
```

## 1.4 Dictionaries

dict Dict Dictionaries Dictionary

A Dictionary is an associative array: Each entry has a key and a value. The entry can be located with the key. The entries are stored without a specific ordering.

### Dictionary creation

E720 E721 E722 E723

A Dictionary is created with a comma-separated list of entries in curly

braces. Each entry has a key and a value, separated by a colon. Each key can only appear once. Examples:

```
:let mydict = {1: 'one', 2: 'two', 3: 'three'}
:let emptydict = {}
```

E713 E716 E717

A key is always a String. You can use a Number, it will be converted to a String automatically. Thus the String '4' and the number 4 will find the same entry. **Note** that the String '04' and the Number 04 are different, since the Number will be converted to the String '4', leading zeros are dropped. The empty string can also be used as a key.

In **Vim9** script a literal key can be used if it consists only of alphanumeric characters, underscore and dash, see [vim9-literal-dict](#).

literal-Dict #{}

To avoid having to put quotes around every key the #{} form can be used in legacy script. This does require the key to consist only of ASCII letters, digits, '-' and '\_'. Example:

```
:let mydict = #{zero: 0, one_key: 1, two-key: 2, 333: 3}
```

**Note** that 333 here is the string "333". Empty keys are not possible with #{}. In **Vim9** script the #{} form cannot be used because it can be confused with the start of a comment.

A value can be any expression. Using a Dictionary for a value creates a nested Dictionary:

```
:let nestdict = {1: {11: 'a', 12: 'b'}, 2: {21: 'c'}}
```

An extra comma after the last entry is ignored.

## Accessing entries

The normal way to access an entry is by putting the key in square brackets:

```
:let val = mydict["one"]
:let mydict["four"] = 4
```

You can add new entries to an existing Dictionary this way, unlike Lists.

For keys that consist entirely of letters, digits and underscore the following form can be used [expr-entry](#) :

```
:let val = mydict.one
:let mydict.four = 4
```

Since an entry can be any type, also a List and a Dictionary, the indexing and key lookup can be repeated:

```
:echo dict.key[idx].key
```

## Dictionary to List conversion

You may want to loop over the entries in a dictionary. For this you need to turn the Dictionary into a List and pass it to [:for](#).

Most often you want to loop over the keys, using the [keys\(\)](#) function:

```
:for key in keys(mydict)
```

```
: echo key .. ': ' .. mydict[key]
:endifor
```

The List of keys is unsorted. You may want to sort them first:

```
:for key in sort(keys(mydict))
```

To loop over the values use the `values()` function:

```
:for v in values(mydict)
: echo "value: " .. v
:endifor
```

If you want both the key and the value use the `items()` function. It returns a List in which each item is a List with two items, the key and the value:

```
:for [key, value] in items(mydict)
: echo key .. ': ' .. value
:endifor
```

## Dictionary identity

### dict-identity

Just like Lists you need to use `copy()` and `deepcopy()` to make a copy of a Dictionary. Otherwise, assignment results in referring to the same Dictionary:

```
:let onedict = {'a': 1, 'b': 2}
:let adict = onedict
:let adict['a'] = 11
:echo onedict['a']
11
```

Two Dictionaries compare equal if all the key-value pairs compare equal. For more info see `list-identity`.

## Dictionary modification

### dict-modification

To change an already existing entry of a Dictionary, or to add a new entry, use `:let` this way:

```
:let dict[4] = "four"
:let dict['one'] = item
```

Removing an entry from a Dictionary is done with `remove()` or `:unlet`.

Three ways to remove the entry with key "aaa" from dict:

```
:let i = remove(dict, 'aaa')
:unlet dict.aaa
:unlet dict['aaa']
```

Merging a Dictionary with another is done with `extend()`:

```
:call extend(adict, bdict)
```

This extends `adict` with all entries from `bdict`. Duplicate keys cause entries in `adict` to be overwritten. An optional third argument can change this.

**Note** that the order of entries in a Dictionary is irrelevant, thus don't expect `:echo adict` to show the items from `bdict` after the older entries in `adict`.

Weeding out entries from a Dictionary can be done with `filter()` :

```
:call filter(dict, 'v:val =~ "x"')
```

This removes all entries from "dict" with a value not matching 'x'.

This can also be used to remove all entries:

```
call filter(dict, 0)
```

In some situations it is not allowed to remove or add entries to a Dictionary. Especially when iterating over all the entries. You will get [E1313](#) or another error in that case.

## Dictionary function

[Dictionary-function](#) [self](#) [E725](#) [E862](#)

When a function is defined with the "dict" attribute it can be used in a special way with a dictionary. Example:

```
:function Mylen() dict
: return len(self.data)
:endifunction
:let mydict = {'data': [0, 1, 2, 3], 'len': function("Myleen")}
:echo mydict.len()
```

This is like a method in object oriented programming. The entry in the Dictionary is a [Funcref](#) . The local variable "self" refers to the dictionary the function was invoked from. When using [Vim9](#) script you can use classes and objects, see `:class``.

It is also possible to add a function without the "dict" attribute as a [Funcref](#) to a Dictionary, but the "self" variable is not available then.

[numbered-function](#) [anonymous-function](#)

To avoid the extra name for the function it can be defined and directly assigned to a Dictionary in this way:

```
:let mydict = {'data': [0, 1, 2, 3]}
:function mydict.len()
: return len(self.data)
:endifunction
:echo mydict.len()
```

The function will then get a number and the value of `dict.len` is a [Funcref](#) that references this function. The function can only be used through a [Funcref](#) . It will automatically be deleted when there is no [Funcref](#) remaining that refers to it.

It is not necessary to use the "dict" attribute for a numbered function.

If you get an error for a numbered function, you can find out what it is with a trick. Assuming the function is 42, the command is:

```
:function g:42
```

## Functions for Dictionaries

[E715](#)

Functions that can be used with a Dictionary:

```
:if has_key(dict, 'foo') " TRUE if dict has entry with key "foo"
```

```

:if empty(dict) " TRUE if dict is empty
:let l = len(dict) " number of items in dict
:let big = max(dict) " maximum value in dict
:let small = min(dict) " minimum value in dict
:let xs = count(dict, 'x') " count nr of times 'x' appears in dict
:let s = string(dict) " String representation of dict
:call map(dict, '">> " .. v:val') " prepend ">> " to each item

```

## 1.5 Blobs

[blob](#) [Blob](#) [Blobs](#) [E978](#)

A Blob is a binary object. It can be used to read an image from a file and send it over a channel, for example.

A Blob mostly behaves like a [List](#) of numbers, where each number has the value of an 8-bit byte, from 0 to 255.

### Blob creation

A Blob can be created with a [blob-literal](#) :

```
:let b = 0zFF00ED015DAF
```

Dots can be inserted between bytes (pair of hex characters) for readability, they don't change the value:

```
:let b = 0zFF00.ED01.5DAF
```

A blob can be read from a file with [readfile\(\)](#) passing the `{type}` argument set to "B", for example:

```
:let b = readfile('image.png', 'B')
```

A blob can be read from a channel with the [ch\\_readblob\(\)](#) function.

### Blob index

[blob-index](#) [E979](#)

A byte in the Blob can be accessed by putting the index in square brackets after the Blob. Indexes are zero-based, thus the first byte has index zero.

```

:let myblob = 0z00112233
:let byte = myblob[0] " get the first byte: 0x00
:let byte = myblob[2] " get the third byte: 0x22

```

A negative index is counted from the end. Index -1 refers to the last byte in the Blob, -2 to the last but one byte, etc.

```
:let last = myblob[-1] " get the last byte: 0x33
```

To avoid an error for an invalid index use the [get\(\)](#) function. When an item is not available it returns -1 or the default value you specify:

```

:echo get(myblob, idx)
:echo get(myblob, idx, 999)

```

### Blob iteration

The `:for` loop executes commands for each byte of a Blob. The loop variable is

set to each byte in the Blob. Example:

```
:for byte in 0z112233
: call Doit(byte)
:endifor
```

This calls Doit() with 0x11, 0x22 and 0x33.

## Blob concatenation

[blob-concatenation](#)

Two blobs can be concatenated with the "+" operator:

```
:let longblob = myblob + 0z4455
:let longblob = 0z4455 + myblob
```

A blob can be concatenated with another one in-place using `:let+=` :

```
:let myblob += 0z6677
```

See [blob-modification](#) below for more about changing a blob in-place.

## Part of a blob

A part of the Blob can be obtained by specifying the first and last index, separated by a colon in square brackets:

```
:let myblob = 0z00112233
:let shortblob = myblob[1:2] " get 0z1122
:let shortblob = myblob[2:-1] " get 0z2233
```

Omitting the first index is similar to zero. Omitting the last index is similar to -1.

```
:let endblob = myblob[2:] " from item 2 to the end: 0z2233
:let shortblob = myblob[2:2] " Blob with one byte: 0z22
:let otherblob = myblob[:] " make a copy of the Blob
```

If the first index is beyond the last byte of the Blob or the second index is before the first index, the result is an empty Blob. There is no error message.

If the second index is equal to or greater than the length of the list the length minus one is used:

```
:echo myblob[2:8] " result: 0z2233
```

## Blob modification

[blob-modification](#) [E1184](#)

To change a specific byte of a blob use `:let` this way:

```
:let blob[4] = 0x44
```

When the index is just one beyond the end of the Blob, it is appended. Any higher index is an error.

To change a sequence of bytes the `[:]` notation can be used:

```
let blob[1:3] = 0z445566
```

The length of the replaced bytes must be exactly the same as the value provided. [E972](#)

To change part of a blob you can specify the first and last byte to be modified. The value must have the same number of bytes in the range:

```
:let blob[3:5] = 0z334455
```

To add items to a Blob in-place, you can use `:let+=` ( `blob-concatenation` ):

```
:let blobA = 0z1122
:let blobA += 0z3344
```

When two variables refer to the same Blob, changing one Blob in-place will cause the referenced Blob to be changed in-place:

```
:let blobA = 0z1122
:let blobB = blobA
:let blobB += 0z3344
:echo blobA
0z11223344
```

You can also use the functions `add()` , `remove()` and `insert()` .

## Blob identity

Blobs can be compared for equality:

```
if blob == 0z001122
```

And for equal identity:

```
if blob is otherblob
```

`blob-identity` E977

When variable "aa" is a Blob and you assign it to another variable "bb", both variables refer to the same Blob. Then the "is" operator returns true.

When making a copy using `[:]` or `copy()` the values are the same, but the identity is different:

```
:let blob = 0z112233
:let blob2 = blob
:echo blob == blob2
1
:echo blob is blob2
1
:let blob3 = blob[:]
:echo blob == blob3
1
:echo blob is blob3
0
```

Making a copy of a Blob is done with the `copy()` function. Using `[:]` also works, as explained above.

## 1.6 More about variables

`more-variables`

If you need to know the type of a variable or expression, use the `type()` function.

When the '!' flag is included in the '`viminfo`' option, global variables that

start with an uppercase letter, and don't contain a lowercase letter, are stored in the viminfo file `viminfo-file` .

When the `'sessionoptions'` option contains "global", global variables that start with an uppercase letter and contain at least one lowercase letter are stored in the session file `session-file` .

variable name	can be stored where
<code>my_var_6</code>	not
<code>My_Var_6</code>	session file
<code>MY_VAR_6</code>	viminfo file

In legacy script it is possible to form a variable name with curly braces, see `curly-braces-names` .

---

## 2. Expression syntax

`expression-syntax`  
E1143

Expression syntax summary, from least to most significant:

<code>expr1</code>	<code>expr2</code> <code>expr2 ? expr1 : expr1</code>	if-then-else
<code>expr2</code>	<code>expr3</code> <code>expr3    expr3 ...</code>	logical OR
<code>expr3</code>	<code>expr4</code> <code>expr4 &amp;&amp; expr4 ...</code>	logical AND
<code>expr4</code>	<code>expr5</code> <code>expr5 == expr5</code> <code>expr5 != expr5</code> <code>expr5 &gt; expr5</code> <code>expr5 &gt;= expr5</code> <code>expr5 &lt; expr5</code> <code>expr5 &lt;= expr5</code> <code>expr5 =~ expr5</code> <code>expr5 !~ expr5</code>  <code>expr5 ==? expr5</code> <code>expr5 ==# expr5</code> etc.	equal not equal greater than greater than or equal smaller than smaller than or equal regex matches regex doesn't match  equal, ignoring case equal, match case As above, append ? for ignoring case, # for matching case
	<code>expr5 is expr5</code> <code>expr5 isnot expr5</code>	same <code>List</code> , <code>Dictionary</code> or <code>Blob</code> instance different <code>List</code> , <code>Dictionary</code> or <code>Blob</code> instance
<code>expr5</code>	<code>expr6</code> <code>expr6 &lt;&lt; expr6</code> <code>expr6 &gt;&gt; expr6</code>	bitwise left shift bitwise right shift
<code>expr6</code>	<code>expr7</code>	

	expr7 + expr7 ...	number addition, list or blob concatenation
	expr7 - expr7 ...	number subtraction
	expr7 . expr7 ...	string concatenation
	expr7 .. expr7 ...	string concatenation
expr7	expr8	
	expr8 * expr8 ...	number multiplication
	expr8 / expr8 ...	number division
	expr8 % expr8 ...	number modulo
expr8	expr9	
	<type>expr9	type check and conversion ( Vim9 only)
expr9	expr10	
	! expr9	logical NOT
	- expr9	unary minus
	+ expr9	unary plus
expr10	expr11	
	expr10[expr1]	byte of a String or item of a List
	expr10[expr1 : expr1]	substring of a String or sublist of a List
	expr10.name	entry in a Dictionary
	expr10(expr1, ...)	function call with Funcref variable
	expr10->name(expr1, ...)	method call
expr11	number	number constant
	"string"	string constant, backslash is special
	'string'	string constant, ' is doubled
	[expr1, ...]	List
	{expr1: expr1, ...}	Dictionary
	#{key: expr1, ...}	legacy Dictionary
	&option	option value
	(expr1)	nested expression
	variable	internal variable
	va{ria}ble	internal variable with curly braces
	\$VAR	environment variable
	@r	contents of register 'r'
	function(expr1, ...)	function call
	func{ti}on(expr1, ...)	function call with curly braces
	{args -> expr1}	legacy lambda expression
	(args) => expr1	Vim9 lambda expression

"..." indicates that the operations in this level can be concatenated.

Example:

```
&nu || &list && &shell == "csh"
```

All expressions within one level are parsed from left to right.

Expression nesting is limited to 1000 levels deep (300 when build with MSVC) to avoid running out of stack and crashing. E1169

expr1 expr1 ternary falsy-operator ?? E109

-----

The ternary operator: `expr2 ? expr1 : expr1`  
The falsy operator: `expr2 ?? expr1`

### Ternary operator

In legacy script the expression before the '?' is evaluated to a number. If it evaluates to `TRUE`, the result is the value of the expression between the '?' and ':', otherwise the result is the value of the expression after the ':':.

In `Vim9` script the first expression must evaluate to a boolean, see `vim9-boolean`.

Example:

```
:echo lnum == 1 ? "top" : lnum
```

Since the first expression is an "expr2", it cannot contain another `?:`. The other two expressions can, thus allow for recursive use of `?:`.

Example:

```
:echo lnum == 1 ? "top" : lnum == 1000 ? "last" : lnum
```

To keep this readable, using `line-continuation` is suggested:

```
:echo lnum == 1
:\ ? "top"
:\ : lnum == 1000
:\ ? "last"
:\ : lnum
```

You should always put a space before the ':', otherwise it can be mistaken for use in a variable such as `"a:1"`.

### Falsy operator

This is also known as the "null coalescing operator", but that's too complicated, thus we just call it the falsy operator.

The expression before the '??' is evaluated. If it evaluates to `truthy`, this is used as the result. Otherwise the expression after the '??' is evaluated and used as the result. This is most useful to have a default value for an expression that may result in zero or empty:

```
echo theList ?? 'list is empty'
echo GetName() ?? 'unknown'
```

These are similar, but not equal:

```
expr2 ?? expr1
expr2 ? expr2 : expr1
```

In the second line "expr2" is evaluated twice. And in `Vim9` script the type of `expr2` before "?" must be a boolean.

expr2 and expr3

expr2 expr3

-----

```
expr3 || expr3 .. logical OR expr-barbar
expr4 && expr4 .. logical AND expr-&&
```

The "||" and "&&" operators take one argument on each side.

In legacy script the arguments are (converted to) Numbers.

In Vim9 script the values must be boolean, see vim9-boolean . Use "!!" to convert any type to a boolean.

The result is:

input		output	
n1	n2	n1    n2	n1 && n2
FALSE	FALSE	FALSE	FALSE
FALSE	TRUE	TRUE	FALSE
TRUE	FALSE	TRUE	FALSE
TRUE	TRUE	TRUE	TRUE

The operators can be concatenated, for example:

```
&nu || &list && &shell == "csh"
```

Note that "&&" takes precedence over "||", so this has the meaning of:

```
&nu || (&list && &shell == "csh")
```

Once the result is known, the expression "short-circuits", that is, further arguments are not evaluated. This is like what happens in C. For example:

```
let a = 1
echo a || b
```

This is valid even if there is no variable called "b" because "a" is TRUE , so the result must be TRUE . Similarly below:

```
echo exists("b") && b == "yes"
```

This is valid whether "b" has been defined or not. The second clause will only be evaluated if "b" has been defined.

```
expr4 expr4 E1153

```

```
expr5 {cmp} expr5
```

Compare two expr5 expressions. In legacy script the result is a 0 if it evaluates to false, or 1 if it evaluates to true. In Vim9 script the result is true or false .

```
expr== expr!= expr-> expr->=
expr-< expr-<= expr==~ expr-!~
expr==# expr-!=# expr-># expr->=#
```

	<code>expr-&lt;#</code>	<code>expr-&lt;=#</code>	<code>expr==~#</code>	<code>expr-!~#</code>
	<code>expr==#?</code>	<code>expr-!#?</code>	<code>expr-&gt;?</code>	<code>expr-&gt;=?</code>
	<code>expr-&lt;?</code>	<code>expr-&lt;=?</code>	<code>expr==~?</code>	<code>expr-!~?</code>
	<code>expr-is</code>	<code>expr-isnot</code>	<code>expr-is#</code>	<code>expr-isnot#</code>
	<code>expr-is?</code>	<code>expr-isnot?</code>	E1072	
	use 'ignorecase'	match case	ignore case	
equal	<code>==</code>	<code>==#</code>	<code>==?</code>	
not equal	<code>!=</code>	<code>!=#</code>	<code>!=?</code>	
greater than	<code>&gt;</code>	<code>&gt;#</code>	<code>&gt;?</code>	
greater than or equal	<code>&gt;=</code>	<code>&gt;=#</code>	<code>&gt;=?</code>	
smaller than	<code>&lt;</code>	<code>&lt;#</code>	<code>&lt;?</code>	
smaller than or equal	<code>&lt;=</code>	<code>&lt;=#</code>	<code>&lt;=?</code>	
regexp matches	<code>==~</code>	<code>==~#</code>	<code>==~?</code>	
regexp doesn't match	<code>!~</code>	<code>!~#</code>	<code>!~?</code>	
same instance	<code>is</code>	<code>is#</code>	<code>is?</code>	
different instance	<code>isnot</code>	<code>isnot#</code>	<code>isnot?</code>	

Examples:

`"abc" ==# "Abc"` evaluates to 0

`"abc" ==? "Abc"` evaluates to 1

`"abc" == "Abc"` evaluates to 1 if 'ignorecase' is set, 0 otherwise

NOTE: In Vim9 script 'ignorecase' is not used.

E691 E692

A **List** can only be compared with a **List** and only "equal", "not equal", "is" and "isnot" can be used. This compares the values of the list, recursively. Ignoring case means case is ignored when comparing item values.

E735 E736

A **Dictionary** can only be compared with a **Dictionary** and only "equal", "not equal", "is" and "isnot" can be used. This compares the key/values of the **Dictionary** recursively. Ignoring case means case is ignored when comparing item values.

E694

A **Funcref** can only be compared with a **Funcref** and only "equal", "not equal", "is" and "isnot" can be used. Case is never ignored. Whether arguments or a Dictionary are bound (with a partial) matters. The Dictionaries must also be equal (or the same, in case of "is") and the arguments must be equal (or the same).

To compare Funcrefs to see if they refer to the same function, ignoring bound Dictionary and arguments, use `get()` to get the function name:

```
if get(Part1, 'name') == get(Part2, 'name')
 " Part1 and Part2 refer to the same function
```

E1037

Using "is" or "isnot" with a **List**, **Dictionary** or **Blob** checks whether the expressions are referring to the same **List**, **Dictionary** or **Blob** instance. A copy of a **List** is different from the original **List**. When using "is" without a **List**, **Dictionary** or **Blob**, it is equivalent to using "equal", using "isnot" equivalent to using "not equal". Except that a different type means the values are different:

```
echo 4 == '4'
1
```

```

echo 4 is '4'
0
echo 0 is []
0

```

"is#" / "isnot#" and "is?" / "isnot?" can be used to match and ignore case. In Vim9 script this doesn't work, two strings are never identical.

In legacy script, when comparing a String with a Number, the String is converted to a Number, and the comparison is done on Numbers. This means that:

```

echo 0 == 'x'
1

```

because 'x' converted to a Number is zero. However:

```

echo [0] == ['x']
0

```

Inside a List or Dictionary this conversion is not used.

In Vim9 script the types must match.

When comparing two Strings, this is done with strcmp() or stricmp(). This results in the mathematical difference (comparing byte values), not necessarily the alphabetical difference in the local language.

When using the operators with a trailing '#', or the short version and 'ignorecase' is off, the comparing is done with strcmp(): case matters.

When using the operators with a trailing '?', or the short version and 'ignorecase' is set, the comparing is done with stricmp(): case is ignored.

'smartcase' is not used.

The "=~" and "!~" operators match the lefthand argument with the righthand argument, which is used as a pattern. See [pattern](#) for what a pattern is. This matching is always done like 'magic' was set and 'coptions' is empty, no matter what the actual value of 'magic' or 'coptions' is. This makes scripts portable. To avoid backslashes in the regexp pattern to be doubled, use a single-quote string, see [literal-string](#).

Since a string is considered to be a single line, a multi-line pattern (containing \n, backslash-n) will not match. However, a literal NL character can be matched like an ordinary character. Examples:

```

"foo\nbar" =~ "\n" evaluates to 1
"foo\nbar" =~ "\\n" evaluates to 0

```

expr5

expr5 bitwise-shift

-----

expr6 << expr6 bitwise left shift  
expr6 >> expr6 bitwise right shift

expr-<<  
expr->>

E1282 E1283

The "<<" and ">>" operators can be used to perform bitwise left or right shift of the left operand by the number of bits specified by the right operand. The operands are used as positive numbers. When shifting right with ">>" the topmost bit (sometimes called the sign bit) is cleared. If the right operand (shift amount) is more than the maximum number of bits in a number

( `v:numbersize` ) the result is zero.

<code>expr6</code> and <code>expr7</code>	<code>expr6</code>	<code>expr7</code>	E1036	E1051
<code>expr7 + expr7</code>	Number addition,	<code>List</code> or <code>Blob</code>	concatenation	<code>expr++</code>
<code>expr7 - expr7</code>	Number subtraction			<code>expr--</code>
<code>expr7 . expr7</code>	String concatenation			<code>expr-.</code>
<code>expr7 .. expr7</code>	String concatenation			<code>expr-..</code>

For `Lists` only "+" is possible and then both `expr7` must be a list. The result is a new list with the two lists Concatenated.

For String concatenation `".."` is preferred, since `"."` is ambiguous, it is also used for `Dict` member access and floating point numbers.

In `Vim9` script and when `vimscript-version` is 2 or higher, using `"."` is not allowed.

In `Vim9` script the arguments of `".."` are converted to String for simple types: Number, Float, Special and Bool. For other types `string()` should be used.

<code>expr8 * expr8</code>	Number multiplication	<code>expr-star</code>
<code>expr8 / expr8</code>	Number division	<code>expr-/</code>
<code>expr8 % expr8</code>	Number modulo	<code>expr-%</code>

In legacy script, for all operators except `"."` and `".."`, Strings are converted to Numbers.

For bitwise operators see `and()` , `or()` and `xor()` .

**Note** the difference between "+" and `".."` in legacy script:

```
"123" + "456" = 579
"123" .. "456" = "123456"
```

Since `'..'` has the same precedence as '+' and '-', you need to read:

```
1 .. 90 + 90.0
```

As:

```
(1 .. 90) + 90.0
```

That works in legacy script, since the String "190" is automatically converted to the Number 190, which can be added to the Float 90.0. However:

```
1 .. 90 * 90.0
```

Should be read as:

```
1 .. (90 * 90.0)
```

Since `'..'` has lower precedence than '\*'. This does NOT work, since this attempts to concatenate a Float and a String.

When dividing a Number by zero the result depends on the value:

```
0 / 0 = -0x80000000 (like NaN for Float)
>0 / 0 = 0x7fffffff (like positive infinity)
<0 / 0 = -0x7fffffff (like negative infinity)
(before Vim 7.2 it was always 0x7fffffff)
```

In `Vim9` script dividing a number by zero is an error. `E1154`

When 64-bit Number support is enabled:

```
0 / 0 = -0x8000000000000000 (like NaN for Float)
>0 / 0 = 0x7fffffffffffffff (like positive infinity)
<0 / 0 = -0x7fffffffffffffff (like negative infinity)
```

When the righthand side of '%' is zero, the result is 0.

None of these work for [Funcrefs](#).

(".", ".." and "%") do not work for Float. [E804](#) [E1035](#)

```
expr8 expr8

<type>expr9
```

This is only available in [Vim9](#) script, see [type-casting](#).

```
expr9 expr9

! expr9 logical NOT expr-!
- expr9 unary minus expr-unary--
+ expr9 unary plus expr-unary-+
```

For '!' [TRUE](#) becomes [FALSE](#), [FALSE](#) becomes [TRUE](#) (one).  
For '-' the sign of the number is changed.  
For '+' the number is unchanged. [Note](#): "++" has no effect.

In legacy script a String will be converted to a Number first. [Note](#) that if the string does not start with a digit you likely don't get what you expect.

In [Vim9](#) script an error is given when "-" or "+" is used and the type is not a number.

In [Vim9](#) script "!" can be used for any type and the result is always a boolean. Use "!!" to convert any type to a boolean, according to whether the value is [falsy](#).

These three can be repeated and mixed. Examples:

```
!-1 == 0
!!8 == 1
--9 == 9
```

```
expr10 expr10

```

This expression is either [expr11](#) or a sequence of the alternatives below, in any order. E.g., these are all possible:

```
expr10[expr1].name
expr10.name[expr1]
expr10(expr1, ...)[expr1].name
expr10->(expr1, ...)[expr1]
```

Evaluation is always from left to right.

expr10[expr1]                    item of String or List                    expr-[]                    E111  
E909                    subscript                    E1062

In legacy Vim script:

If expr10 is a Number or String this results in a String that contains the expr1'th single byte from expr10. expr10 is used as a String (a number is automatically converted to a String), expr1 as a Number. This doesn't recognize multibyte encodings, see `byteidx()` for an alternative, or use `split()` to turn the string into a list of characters. Example, to get the byte under the cursor:

```
:let c = getline(".")[col(".") - 1]
```

In Vim9 script:

E1147                    E1148

If expr10 is a String this results in a String that contains the expr1'th single character (including any composing characters) from expr10. To use byte indexes use `strpart()`.

Index zero gives the first byte or character. Careful: text column numbers start with one!

If the length of the String is less than the index, the result is an empty String. A negative index always results in an empty string (reason: backward compatibility). Use `[-1:]` to get the last byte or character.

In Vim9 script a negative index is used like with a list: count from the end.

If expr10 is a List then it results the item at index expr1. See [list-index](#) for possible index values. If the index is out of range this results in an error. Example:

```
:let item = mylist[-1] " get last item
```

Generally, if a List index is equal to or higher than the length of the List, or more negative than the length of the List, this results in an error.

expr10[expr1a : expr1b] substring or sublist                    expr-[:]                    substring

If expr10 is a String this results in the substring with the bytes or characters from expr1a to and including expr1b. expr10 is used as a String, expr1a and expr1b are used as a Number.

In legacy Vim script the indexes are byte indexes. This doesn't recognize multibyte encodings, see `byteidx()` for computing the indexes. If expr10 is a Number it is first converted to a String.

In Vim9 script the indexes are character indexes and include composing characters. To use byte indexes use `strpart()`. To use character indexes without including composing characters use `strcharpart()`.

The item at index expr1b is included, it is inclusive. For an exclusive index use the `slice()` function.

If expr1a is omitted zero is used. If expr1b is omitted the length of the string minus one is used.

A negative number can be used to measure from the end of the string. -1 is the last character, -2 the last but one, etc.

If an index goes out of range for the string characters are omitted. If `expr1b` is smaller than `expr1a` the result is an empty string.

Examples:

```
:let c = name[-1:] " last byte of a string
:let c = name[0:-1] " the whole string
:let c = name[-2:-2] " last but one byte of a string
:let s = line(".")[4:] " from the fifth byte to the end
:let s = s[:-3] " remove last two bytes
```

**slice**

If `expr10` is a **List** this results in a new **List** with the items indicated by the indexes `expr1a` and `expr1b`. This works like with a **String**, as explained just above. Also see **sublist** below. Examples:

```
:let l = mylist[:3] " first four items
:let l = mylist[4:4] " List with one item
:let l = mylist[:] " shallow copy of a List
```

If `expr10` is a **Blob** this results in a new **Blob** with the bytes in the indexes `expr1a` and `expr1b`, inclusive. Examples:

```
:let b = 0zDEADBEEF
:let bs = b[1:2] " 0zADBE
:let bs = b[:] " copy of 0zDEADBEEF
```

Using `expr10[expr1]` or `expr10[expr1a : expr1b]` on a **Funcref** results in an error.

Watch out for confusion between a namespace and a variable followed by a colon for a **sublist**:

```
mylist[n:] " uses variable n
mylist[s:] " uses namespace s:, error!
```

`expr10.name` entry in a **Dictionary** **expr-entry**  
E1203 E1229

If `expr10` is a **Dictionary** and it is followed by a dot, then the following name will be used as a key in the **Dictionary**. This is just like: `expr10[name]`.

The name must consist of alphanumeric characters, just like a variable name, but it may start with a number. Curly braces cannot be used.

There must not be white space before or after the dot.

Examples:

```
:let dict = {"one": 1, 2: "two"}
:echo dict.one " shows "1"
:echo dict.2 " shows "two"
:echo dict .2 " error because of space before the dot
```

**Note** that the dot is also used for String concatenation. To avoid confusion always put spaces around the dot for String concatenation.

`expr10(expr1, ...)`      **Funcref** function call      **E1085**

When `expr10` is a **Funcref** type variable, invoke the function it refers to.

`expr10->name([args])`      method call      **method**      **->**  
`expr10->{lambda}([args])`      **E260**      **E276**      **E1265**

For methods that are also available as global functions this is the same as:  
`name(expr10 [, args])`

There can also be methods specifically for the type of "expr10".

This allows for chaining, passing the value that one method returns to the next method:

```
mylist->filter(filterexpr)->map(mapexpr)->sort()->join()
```

Example of using a lambda:

```
GetPercentage()->{x -> x * 100}()->printf('%d%%')
```

When using `->` the **expr9** operators will be applied first, thus:

```
-1.234->string()
```

Is equivalent to:

```
(-1.234)->string()
```

And NOT:

```
-(1.234->string())
```

What comes after `"->"` can be a name, a simple expression (not containing any parenthesis), or any expression in parentheses:

```
base->name(args)
base->some.name(args)
base->alist[idx](args)
base->(getFuncRef())(args)
```

**Note** that in the last call the base is passed to the function resulting from `"(getFuncRef())"`, inserted before "args".      **E1275**

**E274**

`"->name("` must not contain white space. There can be white space before the `"->"` and after the `"("`, thus you can split the lines like this:

```
mylist
 \ ->filter(filterexpr)
 \ ->map(mapexpr)
 \ ->sort()
 \ ->join()
```

When using the lambda form there must be no white space between the `}` and the `(`.

**expr11**

number

-----  
number

number constant

expr-number

0x hex-number 0o octal-number binary-number  
Decimal, Hexadecimal (starting with 0x or 0X), Binary (starting with 0b or 0B)  
and Octal (starting with 0, 0o or 0O).

Assuming 64 bit numbers are used (see `v:numbersize`) an unsigned number is truncated to 0x7fffffffffffffff or 9223372036854775807. You can use -1 to get 0xffffffffffffffff.

floating-point-format

Floating point numbers can be written in two forms:

```
[+]{N}.{M}
[+]{N}.{M}[eE][+]{exp}
```

{N} and {M} are numbers. Both {N} and {M} must be present and can only contain digits, except that in Vim9 script in {N} single quotes between digits are ignored.

[+] means there is an optional plus or minus sign.

{exp} is the exponent, power of 10.

Only a decimal point is accepted, not a comma. No matter what the current locale is.

Examples:

```
123.456
+0.0001
55.0
-0.123
1.234e03
1.0E-6
-3.1416e+88
```

These are INVALID:

```
3. empty {M}
1e40 missing .{M}
```

Rationale:

Before floating point was introduced, the text "123.456" was interpreted as the two numbers "123" and "456", both converted to a string and concatenated, resulting in the string "123456". Since this was considered pointless, and we could not find it intentionally being used in Vim scripts, this backwards incompatibility was accepted in favor of being able to use the normal notation for floating point numbers.

float-pi float-e

A few useful values to copy&paste:

```
:let pi = 3.14159265359
:let e = 2.71828182846
```

Or, if you don't want to write them in as floating-point literals, you can also use functions, like the following:

```
:let pi = acos(-1.0)
:let e = exp(1.0)
```

## floating-point-precision

The precision and range of floating points numbers depends on what "double" means in the library Vim was compiled with. There is no way to change this at runtime.

The default for displaying a `Float` is to use 6 decimal places, like using `printf("%g", f)`. You can select something else when using the `printf()` function. Example:

```
:echo printf('%.15e', atan(1))
7.853981633974483e-01
```

<code>string</code>	<code>string</code>	<code>String</code>	<code>expr-string</code>	<code>E114</code>
<code>"string"</code>	string constant	<code>expr-quote</code>		

**Note** that double quotes are used.

A string constant accepts these special characters:

- `\...` three-digit octal number (e.g., `"\316"`)
- `\..` two-digit octal number (must be followed by non-digit)
- `\.` one-digit octal number (must be followed by non-digit)
- `\x..` byte specified with two hex numbers (e.g., `"\x1f"`)
- `\x.` byte specified with one hex number (must be followed by non-hex char)
- `\X..` same as `\x..`
- `\X.` same as `\x.`
- `\u....` character specified with up to 4 hex numbers, stored according to the current value of `'encoding'` (e.g., `"\u02a4"`)
- `\U....` same as `\u` but allows up to 8 hex numbers.
- `\b` backspace `<BS>`
- `\e` escape `<Esc>`
- `\f` formfeed `0x0C`
- `\n` newline `<NL>`
- `\r` return `<CR>`
- `\t` tab `<Tab>`
- `\\` backslash
- `\"` double quote
- `\<xxx>` Special key named "xxx". e.g. `"\<C-W>"` for **CTRL-W**. This is for use in mappings, the `0x80` byte is escaped. To use the double quote character it must be escaped: `"<M-\>"`. Don't use `<Char-xxxx>` to get a UTF-8 character, use `\uxxxx` as mentioned above.
- `\<*xxx>` Like `\<xxx>` but prepends a modifier instead of including it in the character. E.g. `"\<C-w>"` is one character `0x17` while `"\<*C-w>"` is four bytes: 3 for the CTRL modifier and then character "W".

**Note** that `"\xff"` is stored as the byte 255, which may be invalid in some encodings. Use `"\u00ff"` to store character 255 according to the current value of `'encoding'`.

**Note** that `"\000"` and `"\x00"` force the end of the string.

## blob-literal

---

blob-literal E973

Hexadecimal starting with 0z or 0Z, with an arbitrary number of bytes. The sequence must be an even number of hex characters. Example:

```
:let b = 0zFF00ED015DAF
```

## literal-string

---

literal-string E115

'string' string constant

expr-'

Note that single quotes are used.

This string is taken as it is. No backslashes are removed or have a special meaning. The only exception is that two quotes stand for one quote.

Single quoted strings are useful for patterns, so that backslashes do not need to be doubled. These two commands are equivalent:

```
if a =~ "\\s*"
if a =~ '\s'
```

## interpolated-string

---

\$quote interpolated-string

\$"string" interpolated string constant expr-\$quote  
\$'string' interpolated literal string constant expr-\$'

Interpolated strings are an extension of the `string` and `literal-string`, allowing the inclusion of Vim script expressions (see `expr1`). Any expression returning a value can be enclosed between curly braces. The value is converted to a string. All the text and results of the expressions are concatenated to make a new string.

E1278 E1279

To include an opening brace '{' or closing brace '}' in the string content double it. For double quoted strings using a backslash also works. A single closing brace '}' will result in an error.

Examples:

```
let your_name = input("What's your name? ")
What's your name? Peter

echo
echo $"Hello, {your_name}!"
Hello, Peter!

echo $"The square root of {{9}} is {sqrt(9)}"
The square root of {9} is 3.0
```

string-offset-encoding

A string consists of multiple characters. How the characters are stored depends on 'encoding'. Most common is UTF-8, which uses one byte for ASCII characters, two bytes for other latin characters and more bytes for other

characters.

A string offset can count characters or bytes. Other programs may use UTF-16 encoding (16-bit words) and an offset of UTF-16 words. Some functions use byte offsets, usually for UTF-8 encoding. Other functions use character offsets, in which case the encoding doesn't matter.

The different offsets for the string "a☺" are below:

UTF-8 offsets:

[0]: 61, [1]: C2, [2]: A9, [3]: F0, [4]: 9F, [5]: 98, [6]: 8A

UTF-16 offsets:

[0]: 0061, [1]: 00A9, [2]: D83D, [3]: DE0A

UTF-32 (character) offsets:

[0]: 00000061, [1]: 000000A9, [2]: 0001F60A

You can use the "g8" and "ga" commands on a character to see the decimal/hex/octal values.

The functions `byteidx()`, `utf16idx()` and `charidx()` can be used to convert between these indices. The functions `strlen()`, `strutf16len()` and `strcharlen()` return the number of bytes, UTF-16 code units and characters in a string respectively.

option expr-option E112 E113

-----

<code>&amp;option</code>	option value, local value if possible
<code>&amp;g:option</code>	global option value
<code>&amp;l:option</code>	local option value

Examples:

```
echo "tabstop is " .. &tabstop
if &insertmode
```

Any option name can be used here. See [options](#). When using the local value and there is no buffer-local or window-local value, the global value is used anyway.

register expr-register @r

-----

@r contents of register 'r'

The result is the contents of the named register, as a single string. Newlines are inserted where required. To get the contents of the unnamed register use "@" or "@@". See [registers](#) for an explanation of the available registers.

When using the '=' register you get the expression itself, not what it evaluates to. Use `eval()` to evaluate it.

nesting expr-nesting E110

-----

(expr1)                    nested expression

environment variable                    [expr-env](#)

-----  
\$VAR                    environment variable

The String value of any environment variable. When it is not defined, the result is an empty string.

The functions ``getenv()`` and ``setenv()`` can also be used and work for environment variables with non-alphanumeric names. The function ``environ()`` can be used to get a Dict with all environment variables.

[expr-env-expand](#)

**Note** that there is a difference between using \$VAR directly and using `expand("$VAR")`. Using it directly will only expand environment variables that are known inside the current Vim session. Using `expand()` will first try using the environment variables known inside the current Vim session. If that fails, a shell will be used to expand the variable. This can be slow, but it does expand all variables that the shell knows about. Example:

```
:echo $shell
:echo expand("$shell")
```

The first one probably doesn't echo anything, the second echoes the \$shell variable (if your shell supports it).

internal variable                    [expr-variable](#)    [E1015](#)    [E1089](#)

-----  
variable                    internal variable  
See below [internal-variables](#) .

function call                    [expr-function](#)    [E116](#)    [E118](#)    [E119](#)    [E120](#)

-----  
function(expr1, ...)    function call  
See below [functions](#) .

lambda expression                    [expr-lambda](#)    [lambda](#)

-----  
{args -> expr1}                    legacy lambda expression                    [E451](#)  
(args) => expr1                    [Vim9](#) lambda expression

A lambda expression creates a new unnamed function which returns the result of evaluating `expr1` . Lambda expressions differ from [user-functions](#) in the following ways:

1. The body of the lambda expression is an `expr1` and not a sequence of [Ex](#) commands.
2. The prefix "a:" should not be used for arguments. E.g.:  

```
:let F = {arg1, arg2 -> arg1 - arg2}
```

```
:echo F(5, 2)
3
```

The arguments are optional. Example:

```
:let F = {-> 'error function'}
:echo F('ignored')
error function
```

The [Vim9](#) lambda does not only use a different syntax, it also adds type checking and can be split over multiple lines, see [vim9-lambda](#) .

### closure

Lambda expressions can access outer scope variables and arguments. This is often called a closure. Example where "i" and "a:arg" are used in a lambda while they already exist in the function scope. They remain valid even after the function returns:

```
:function Foo(arg)
: let i = 3
: return {x -> x + i - a:arg}
:endfunction
:let Bar = Foo(4)
:echo Bar(6)
5
```

**Note** that the variables must exist in the outer scope before the lambda is defined for this to work. See also [:func-closure](#) .

Lambda and closure support can be checked with:

```
if has('lambda')
```

Examples for using a lambda expression with [sort\(\)](#) , [map\(\)](#) and [filter\(\)](#) :

```
:echo map([1, 2, 3], {idx, val -> val + 1})
[2, 3, 4]
:echo sort([3,7,2,1,4], {a, b -> a - b})
[1, 2, 3, 4, 7]
```

The lambda expression is also useful for Channel, Job and timer:

```
:let timer = timer_start(500,
\ {-> execute("echo 'Handler called'", "")},
\ {'repeat': 3})
```

```
Handler called
Handler called
Handler called
```

**Note** that it is possible to cause memory to be used and not freed if the closure is referenced by the context it depends on:

```
function Function()
let x = 0
let F = {-> x}
endfunction
```

The closure uses "x" from the function scope, and "F" in that same scope refers to the closure. This cycle results in the memory not being freed. Recommendation: don't do this.

Notice how `execute()` is used to execute an Ex command. That's ugly though. In Vim9 script you can use a command block, see [inline-function](#) .

Although you can use the loop variable of a ``for`` command, it must still exist when the closure is called, otherwise you get an error. [E1302](#)

Lambda expressions have internal names like `'<lambda>42'`. If you get an error for a lambda expression, you can find what it is with the following command:

```
:function <lambda>42
```

See also: [numbered-function](#)

---

### 3. Internal variable [internal-variables](#) [E461](#) [E1001](#)

An internal variable name can be made up of letters, digits and `'_'`. But it cannot start with a digit. In legacy script it is also possible to use curly braces, see [curly-braces-names](#) .

In legacy script an internal variable is created with the `":let"` command `:let` . An internal variable is explicitly destroyed with the `":unlet"` command `:unlet` .

Using a name that is not an internal variable or refers to a variable that has been destroyed results in an error.

In Vim9 script ``:let`` is not used and variables work differently, see [:var](#) .

### [variable-scope](#)

There are several name spaces for variables. Which one is to be used is specified by what is prepended:

	(nothing)	In a function: local to the function; in a legacy script: global; in a Vim9 script: local to the script
<a href="#">buffer-variable</a>	b:	Local to the current buffer.
<a href="#">window-variable</a>	w:	Local to the current window.
<a href="#">tabpage-variable</a>	t:	Local to the current tab page.
<a href="#">global-variable</a>	g:	Global.
<a href="#">local-variable</a>	l:	Local to a function (only in a legacy function)
<a href="#">script-variable</a>	s:	Local to a <code>:source</code> 'ed Vim script.
<a href="#">function-argument</a>	a:	Function argument (only in a legacy function).
<a href="#">vim-variable</a>	v:	Global, predefined by Vim.

The scope name by itself can be used as a [Dictionary](#) . For example, to delete all script-local variables:

```
:for k in keys(s:)
: unlet s:[k]
:endfor
```

**Note:** in Vim9 script variables can also be local to a block of commands, see [vim9-scopes](#) .

### [buffer-variable](#) [b:var](#) [b:](#)

A variable name that is preceded with `"b:"` is local to the current buffer.

Thus you can have several `"b:foo"` variables, one for each buffer.

This kind of variable is deleted when the buffer is wiped out or deleted with

`:bdelete .`

One local buffer variable is predefined:

`b:changedtick`     `b:changedtick`     `changetick`  
The total number of changes to the current buffer. It is incremented for each change. An undo command is also a change in this case. Resetting `'modified'` when writing the buffer is also counted. This can be used to perform an action only when the buffer has changed. Example:

```
:if my_changedtick != b:changedtick
: let my_changedtick = b:changedtick
: call My_Update()
:endif
```

You cannot change or delete the `b:changedtick` variable. If you need more information about the change see `listener_add()` .

`w:var`     `w:`  
A variable name that is preceded with "w:" is local to the current window. It is deleted when the window is closed.

`t:var`     `t:`  
A variable name that is preceded with "t:" is local to the current tab page, It is deleted when the tab page is closed. {not available when compiled without the `+windows` feature}

`g:var`     `g:`  
Inside functions and in `Vim9` script global variables are accessed with "g:". Omitting this will access a variable local to a function or script. "g:" can also be used in any other place if you like.

`l:var`     `l:`  
Inside functions local variables are accessed without prepending anything. But you can also prepend "l:" if you like. However, without prepending "l:" you may run into reserved variable names. For example "count". By itself it refers to "v:count". Using "l:count" you can have a local variable with the same name.

`s:var`  
In a legacy Vim script variables starting with "s:" can be used. They cannot be accessed from outside of the scripts, thus are local to the script. In `Vim9` script the "s:" prefix can be omitted, variables are script-local by default.

They can be used in:

- commands executed while the script is sourced
- functions defined in the script
- autocommands defined in the script
- functions and autocommands defined in functions and autocommands which were defined in the script (recursively)
- user defined commands defined in the script

Thus not in:

- other scripts sourced from this one

- mappings
- menus
- etc.

Script variables can be used to avoid conflicts with global variable names. Take this example:

```
let s:counter = 0
function MyCounter()
 let s:counter = s:counter + 1
 echo s:counter
endfunction
command Tick call MyCounter()
```

You can now invoke "Tick" from any script, and the "s:counter" variable in that script will not be changed, only the "s:counter" in the script where "Tick" was defined is used.

Another example that does the same:

```
let s:counter = 0
command Tick let s:counter = s:counter + 1 | echo s:counter
```

When calling a function and invoking a user-defined command, the context for script variables is set to the script where the function or command was defined.

The script variables are also available when a function is defined inside a function that is defined in a script. Example:

```
let s:counter = 0
function StartCounting(incr)
 if a:incr
 function MyCounter()
 let s:counter = s:counter + 1
 endfunction
 else
 function MyCounter()
 let s:counter = s:counter - 1
 endfunction
 endif
endfunction
```

This defines the MyCounter() function either for counting up or counting down when calling StartCounting(). It doesn't matter from where StartCounting() is called, the s:counter variable will be accessible in MyCounter().

When the same script is sourced again it will use the same script variables. They will remain valid as long as Vim is running. This can be used to maintain a counter:

```
if !exists("s:counter")
 let s:counter = 1
 echo "script executed for the first time"
```

```

else
 let s:counter = s:counter + 1
 echo "script executed " .. s:counter .. " times now"
endif

```

**Note** that this means that filetype plugins don't get a different set of script variables for each buffer. Use local buffer variables instead `b:var` .

## PREDEFINED VIM VARIABLES

vim-variable v:var v:  
E963 E1063

Most variables are read-only, when a variable can be set by the user, it will be mentioned at the variable description below. The type cannot be changed.

v:argv	<code>v:argv</code> argv-variable The command line arguments Vim was invoked with. This is a list of strings. The first item is the Vim command. See <code>v:progbath</code> for the command with full path.
v:beval_col	<code>v:beval_col</code> beval_col-variable The number of the column, over which the mouse pointer is. This is the byte index in the <code>v:beval_lnum</code> line. Only valid while evaluating the <code>'balloonexpr'</code> option.
v:beval_bufnr	<code>v:beval_bufnr</code> beval_bufnr-variable The number of the buffer, over which the mouse pointer is. Only valid while evaluating the <code>'balloonexpr'</code> option.
v:beval_lnum	<code>v:beval_lnum</code> beval_lnum-variable The number of the line, over which the mouse pointer is. Only valid while evaluating the <code>'balloonexpr'</code> option.
v:beval_text	<code>v:beval_text</code> beval_text-variable The text under or after the mouse pointer. Usually a word as it is useful for debugging a C program. <code>'iskeyword'</code> applies, but a dot and <code>"-&gt;"</code> before the position is included. When on a <code>']'</code> the text before it is used, including the matching <code>'['</code> and word before it. When on a Visual area within one line the highlighted text is used. Also see <code>&lt;cexpr&gt;</code> . Only valid while evaluating the <code>'balloonexpr'</code> option.
v:beval_winnr	<code>v:beval_winnr</code> beval_winnr-variable The number of the window, over which the mouse pointer is. Only valid while evaluating the <code>'balloonexpr'</code> option. The first window has number zero (unlike most other places where a window gets a number).
v:beval_winid	<code>v:beval_winid</code> beval_winid-variable The <code>window-ID</code> of the window, over which the mouse pointer is. Otherwise like <code>v:beval_winnr</code> .
v:char	<code>v:char</code> char-variable Argument for evaluating <code>'formatexpr'</code> and used for the typed character when using <code>&lt;expr&gt;</code> in an abbreviation <code>:map-&lt;expr&gt;</code> .

It is also used by the `InsertCharPre` , `InsertEnter` and `KeyInputPre` events.

- `v:charconvert_from` `charconvert_from-variable`
- `v:charconvert_from`  
The name of the character encoding of a file to be converted. Only valid while evaluating the `'charconvert'` option.
- `v:charconvert_to` `charconvert_to-variable`
- `v:charconvert_to`  
The name of the character encoding of a file after conversion. Only valid while evaluating the `'charconvert'` option.
- `v:cmdarg` `cmdarg-variable`
- `v:cmdarg`  
This variable is used for two purposes:
1. The extra arguments given to a file read/write command. Currently these are `"++enc="` and `"++ff="`. This variable is set before an autocommand event for a file read/write command is triggered. There is a leading space to make it possible to append this variable directly after the read/write command. **Note:** The `"cmd"` argument isn't included here, because it will be executed anyway.
  2. When printing a PostScript file with `":hardcopy"` this is the argument for the `":hardcopy"` command. This can be used in `'printexpr'`.
- `v:cmbang` `cmbang-variable`
- `v:cmbang`  
Set like `v:cmdarg` for a file read/write command. When a `"!"` was used the value is 1, otherwise it is 0. **Note** that this can only be used in autocommands. For user commands `<bang>` can be used.
- `v:collate` `collate-variable`
- `v:collate`  
The current locale setting for collation order of the runtime environment. This allows Vim scripts to be aware of the current locale encoding. Technical: it's the value of `LC_COLLATE`. When not using a locale the value is `"C"`. This variable can not be set directly, use the `:language` command.  
See `multi-lang` .
- `v:colornames` `colornames`
- `v:colornames`  
A dictionary that maps color names to hex color strings. These color names can be used with the `highlight-guifg` , `highlight-guibg` , and `highlight-guisp` parameters.
- The key values in the dictionary (the color names) should be lower cased, because Vim looks up a color by its lower case name.
- Updating an entry in `v:colornames` has no immediate effect on the syntax highlighting. The highlight commands (probably in a colorscheme script) need to be re-evaluated in order to use the updated color values. For example:

```

:let v:colornames['fuchsia'] = '#cf3ab4'
:let v:colornames['mauve'] = '#915f6d'
:highlight Normal guifg=fuchsia guibg=mauve

```

This cannot be used to override the `cterm-colors` but it can be used to override other colors. For example, the X11 colors defined in the ``colors/lists/default.vim`` (previously defined in `rgb.txt`). When defining new color names in a plugin, the recommended practice is to set a color entry only when it does not already exist. For example:

```

:call extend(v:colornames, {
\ 'fuchsia': '#cf3ab4',
\ 'mauve': '#915f6d',
\ }, 'keep')

```

Using `extend()` with the `'keep'` option updates each color only if it did not exist in `v:colornames`. Doing so allows the user to choose the precise color value for a common name by setting it in their `.vimrc`.

It is possible to remove entries from this dictionary but doing so is NOT recommended, because it is disruptive to other scripts. It is also unlikely to achieve the desired result because the `:colorscheme` and `:highlight` commands will both automatically load all ``colors/lists/default.vim`` color scripts.

You can make changes to that file, but make sure to add new keys instead of updating existing ones, otherwise Vim will skip loading the file (thinking it hasn't been changed).

`v:completed_item`    `completed_item-variable`

`v:completed_item`

`Dictionary` containing the `complete-items` for the most recently completed word after `CompleteDone`. The `Dictionary` is empty if the completion failed.

**Note:** Plugins can modify the value to emulate the builtin `CompleteDone` event behavior.

`v:count`    `count-variable`

`v:count`

The count given for the last Normal mode command. Can be used to get the count before a mapping. Read-only. Example:

```
:map _x :<C-U>echo "the count is " .. v:count<CR>
```

**Note:** The `<C-U>` is required to remove the line range that you get when typing `:'` after a count.

When there are two counts, as in `"3d2w"`, they are multiplied, just like what happens in the command, `"d6w"` for the example. Also used for evaluating the `'formatexpr'` option.

`"count"` also works, for backwards compatibility, unless `scriptversion` is 3 or higher.

`v:count1`    `count1-variable`

`v:count1` Just like "`v:count`", but defaults to one when no count is used.

`v:ctype` `v:ctype` *ctype-variable*  
The current locale setting for characters of the runtime environment. This allows Vim scripts to be aware of the current locale encoding. Technical: it's the value of `LC_CTYPE`. When not using a locale the value is "C". This variable can not be set directly, use the `:language` command.  
See `multi-lang` .

`v:dying` `v:dying` *dying-variable*  
Normally zero. When a deadly signal is caught it's set to one. When multiple signals are caught the number increases. Can be used in an autocommand to check if Vim didn't terminate normally. {only works on Unix}  
Example:  

```
:au VimLeave * if v:dying | echo "\nAAAAaaaarrggghhh!!!\n" | endif
```

Note: if another deadly signal is caught when `v:dying` is one, `VimLeave` autocommands will not be executed.

`v:exiting` `v:exiting` *exiting-variable*  
Vim exit code. Normally zero, non-zero when something went wrong. The value is `v:null` before invoking the `VimLeavePre` and `VimLeave` autocmds. See `:q` , `:x` and `:cquit` .  
Example:  

```
:au VimLeave * echo "Exit value is " .. v:exiting
```

`v:echospace` `v:echospace` *echospace-variable*  
Number of screen cells that can be used for an `:echo` message in the last screen line before causing the `hit-enter-prompt` . Depends on `'showcmd'` , `'ruler'` and `'columns'` . You need to check `'cmdheight'` for whether there are full-width lines available above the last line.

`v:errmsg` `v:errmsg` *errmsg-variable*  
Last given error message. It's allowed to set this variable.  
Example:  

```
:let v:errmsg = ""
:silent! next
:if v:errmsg != ""
: ... handle error
```

`"errmsg"` also works, for backwards compatibility, unless `scriptversion` is 3 or higher.

`v:errors` `v:errors` *errors-variable* *assert-return*  
Errors found by assert functions, such as `assert_true()` . This is a list of strings.  
The assert functions append an item when an assert fails. The return value indicates this: a one is returned if an item was added to `v:errors` , otherwise zero is returned.  
To remove old results make it empty:  

```
:let v:errors = []
```

If `v:errors` is set to anything but a list it is made an empty list by the `assert` function.

`v:event` `v:event` `event-variable`  
Dictionary containing information about the current `autocommand`. See the specific event for what it puts in this dictionary.  
The dictionary is emptied when the `autocommand` finishes, please refer to `dict-identity` for how to get an independent copy of it. Use `deepcopy()` if you want to keep the information after the event triggers. Example:  

```
au TextYankPost * let g:foo = deepcopy(v:event)
```

`v:exception` `v:exception` `exception-variable`  
The value of the exception most recently caught and not finished. See also `v:stacktrace`, `v:throwpoint`, and `throw-variables`.  
Example:

```
:try
: throw "oops"
:catch /.*/
: echo "caught " .. v:exception
:endtry
```

Output: "caught oops".

`v:false` `v:false` `false-variable`  
A Number with value zero. Used to put "false" in JSON. See `json_encode()`.  
When used as a string this evaluates to "v:false".  

```
echo v:false
v:false
```

  
That is so that `eval()` can parse the string back to the same value. Read-only.  
In `Vim9` script "false" can be used which has a boolean type.

`v:fcs_reason` `v:fcs_reason` `fcs_reason-variable`  
The reason why the `FileChangedShell` event was triggered. Can be used in an autocommand to decide what to do and/or what to set `v:fcs_choice` to. Possible values:

deleted	file no longer exists
conflict	file contents, mode or timestamp was changed and buffer is modified
changed	file contents has changed
mode	mode of file changed
time	only file timestamp changed

`v:fcs_choice` `v:fcs_choice` `fcs_choice-variable`  
What should happen after a `FileChangedShell` event was triggered. Can be used in an autocommand to tell Vim what to do with the affected buffer:

reload	Reload the buffer (does not work if the file was deleted).
edit	Reload the buffer and detect the values for options such as

	<p><b>'fileformat', 'fileencoding', 'binary'</b>          (does not work if the file was deleted).</p> <p>ask Ask the user what to do, as if there was no autocommand. Except that when only the timestamp changed nothing will happen.</p> <p>&lt;empty&gt; Nothing, the autocommand should do everything that needs to be done.</p> <p>The default is empty. If another (invalid) value is used then Vim behaves like it is empty, there is no warning message.</p>										
v:fname	<p><b>v:fname</b> <i>fname-variable</i></p> <p>When evaluating <b>'includeexpr'</b>: the file name that was detected. Empty otherwise.</p>										
v:fname_in	<p><b>v:fname_in</b> <i>fname_in-variable</i></p> <p>The name of the input file. Valid while evaluating:</p> <table border="0"> <tr> <td><b>option</b></td> <td><b>used for</b></td> </tr> <tr> <td><b>'charconvert'</b></td> <td>file to be converted</td> </tr> <tr> <td><b>'diffexpr'</b></td> <td>original file</td> </tr> <tr> <td><b>'patchexpr'</b></td> <td>original file</td> </tr> <tr> <td><b>'printexpr'</b></td> <td>file to be printed</td> </tr> </table> <p>And set to the swap file name for <code>SwapExists</code> .</p>	<b>option</b>	<b>used for</b>	<b>'charconvert'</b>	file to be converted	<b>'diffexpr'</b>	original file	<b>'patchexpr'</b>	original file	<b>'printexpr'</b>	file to be printed
<b>option</b>	<b>used for</b>										
<b>'charconvert'</b>	file to be converted										
<b>'diffexpr'</b>	original file										
<b>'patchexpr'</b>	original file										
<b>'printexpr'</b>	file to be printed										
v:fname_out	<p><b>v:fname_out</b> <i>fname_out-variable</i></p> <p>The name of the output file. Only valid while evaluating:</p> <table border="0"> <tr> <td><b>option</b></td> <td><b>used for</b></td> </tr> <tr> <td><b>'charconvert'</b></td> <td>resulting converted file (*)</td> </tr> <tr> <td><b>'diffexpr'</b></td> <td>output of diff</td> </tr> <tr> <td><b>'patchexpr'</b></td> <td>resulting patched file</td> </tr> </table> <p>(*) When doing conversion for a write command (e.g., ":w file") it will be equal to v:fname_in. When doing conversion for a read command (e.g., ":e file") it will be a temporary file and different from v:fname_in.</p>	<b>option</b>	<b>used for</b>	<b>'charconvert'</b>	resulting converted file (*)	<b>'diffexpr'</b>	output of diff	<b>'patchexpr'</b>	resulting patched file		
<b>option</b>	<b>used for</b>										
<b>'charconvert'</b>	resulting converted file (*)										
<b>'diffexpr'</b>	output of diff										
<b>'patchexpr'</b>	resulting patched file										
v:fname_new	<p><b>v:fname_new</b> <i>fname_new-variable</i></p> <p>The name of the new version of the file. Only valid while evaluating <b>'diffexpr'</b>.</p>										
v:fname_diff	<p><b>v:fname_diff</b> <i>fname_diff-variable</i></p> <p>The name of the diff (patch) file. Only valid while evaluating <b>'patchexpr'</b>.</p>										
v:folddashes	<p><b>v:folddashes</b> <i>folddashes-variable</i></p> <p>Used for <b>'foldtext'</b>: dashes representing foldlevel of a closed fold.</p> <p>Read-only in the <code>sandbox</code> . <code>fold-foldtext</code></p>										
v:foldlevel	<p><b>v:foldlevel</b> <i>foldlevel-variable</i></p> <p>Used for <b>'foldtext'</b>: foldlevel of closed fold.</p> <p>Read-only in the <code>sandbox</code> . <code>fold-foldtext</code></p>										

v:foldend	<p>Used for <b>'foldtext'</b>: last line of closed fold.  Read-only in the <code>sandbox</code> . <code>fold-foldtext</code></p>						
v:foldstart	<p>Used for <b>'foldtext'</b>: first line of closed fold.  Read-only in the <code>sandbox</code> . <code>fold-foldtext</code></p>						
v:hsearch	<p>Variable that indicates whether search highlighting is on. Setting it makes sense only if <b>'hsearch'</b> is enabled which requires <code>+extra_search</code> . Setting this variable to zero acts like the <code>:nohsearch</code> command, setting it to one acts like <code>let &amp;hsearch = &amp;hsearch</code>  <b>Note</b> that the value is restored when returning from a function. <code>function-search-undo</code> .</p>						
v:insertmode	<p>Used for the <code>InsertEnter</code> and <code>InsertChange</code> autocommand events. Values:</p> <table> <tr> <td>i</td> <td>Insert mode</td> </tr> <tr> <td>r</td> <td>Replace mode</td> </tr> <tr> <td>v</td> <td>Virtual Replace mode</td> </tr> </table>	i	Insert mode	r	Replace mode	v	Virtual Replace mode
i	Insert mode						
r	Replace mode						
v	Virtual Replace mode						
v:key	<p>Key of the current item of a <code>Dictionary</code> . Only valid while evaluating the expression used with <code>map()</code> and <code>filter()</code> .  Read-only.</p>						
v:lang	<p>The current locale setting for messages of the runtime environment. This allows Vim scripts to be aware of the current language. Technical: it's the value of <code>LC_MESSAGES</code>. The value is system dependent.  This variable can not be set directly, use the <code>:language</code> command.  It can be different from <code>v:ctype</code> when messages are desired in a different language than what is used for character encoding. See <code>multi-lang</code> .</p>						
v:lc_time	<p>The current locale setting for time messages of the runtime environment. This allows Vim scripts to be aware of the current language. Technical: it's the value of <code>LC_TIME</code>. This variable can not be set directly, use the <code>:language</code> command. See <code>multi-lang</code> .</p>						
v:lnum	<p>Line number for the <b>'foldexpr'</b> <code>fold-expr</code> , <b>'formatexpr'</b> and <b>'indentexpr'</b> expressions, tab page number for <b>'guitablabel'</b> and <b>'guitabtooltip'</b>. Only valid while one of these expressions is being evaluated. Read-only when in the <code>sandbox</code> .</p>						

v:maxcol	<p style="text-align: right;"><a href="#">v:maxcol</a> <a href="#">maxcol-variable</a></p> <p>Maximum line length. Depending on where it is used it can be screen columns, characters or bytes. The value currently is 2147483647 on all systems.</p>
v:mouse_win	<p style="text-align: right;"><a href="#">v:mouse_win</a> <a href="#">mouse_win-variable</a></p> <p>Window number for a mouse click obtained with <code>getchar()</code> . First window has number 1, like with <code>winnr()</code> . The value is zero when there was no mouse button click.</p>
v:mouse_winid	<p style="text-align: right;"><a href="#">v:mouse_winid</a> <a href="#">mouse_winid-variable</a></p> <p>Window ID for a mouse click obtained with <code>getchar()</code> . The value is zero when there was no mouse button click.</p>
v:mouse_lnum	<p style="text-align: right;"><a href="#">v:mouse_lnum</a> <a href="#">mouse_lnum-variable</a></p> <p>Line number for a mouse click obtained with <code>getchar()</code> . This is the text line number, not the screen line number. The value is zero when there was no mouse button click.</p>
v:mouse_col	<p style="text-align: right;"><a href="#">v:mouse_col</a> <a href="#">mouse_col-variable</a></p> <p>Column number for a mouse click obtained with <code>getchar()</code> . This is the screen column number, like with <code>virtcol()</code> . The value is zero when there was no mouse button click.</p>
v:none	<p style="text-align: right;"><a href="#">v:none</a> <a href="#">none-variable</a> <a href="#">None</a></p> <p>An empty String. Used to put an empty item in JSON. See <code>json_encode()</code> . This can also be used as a function argument to use the default value, see <a href="#">none-function_argument</a> . When used as a number this evaluates to zero. When used as a string this evaluates to "v:none".</p> <pre>echo v:none v:none</pre> <p>That is so that <code>eval()</code> can parse the string back to the same value. Read-only.  <b>Note</b> that using <code>`== v:none`</code> and <code>`!= v:none`</code> will often give an error. Instead, use <code>`is v:none`</code> and <code>`isnot v:none`</code> .</p>
v:null	<p style="text-align: right;"><a href="#">v:null</a> <a href="#">null-variable</a></p> <p>An empty String. Used to put "null" in JSON. See <code>json_encode()</code> . When used as a number this evaluates to zero. When used as a string this evaluates to "v:null".</p> <pre>echo v:null v:null</pre> <p>That is so that <code>eval()</code> can parse the string back to the same value. Read-only.  In <a href="#">Vim9</a> script <code>`null`</code> can be used without "v:". In some places <code>`v:null`</code> and <code>`null`</code> can be used for a List, Dict, Job, etc. that is not set. That is slightly different than an empty List, Dict, etc.</p>
v:numbermax	<p style="text-align: right;"><a href="#">v:numbermax</a> <a href="#">numbermax-variable</a></p> <p>Maximum value of a number.</p>

v:numbermin	<p>Minimum value of a number (negative).</p>	<p>v:numbermin    numbermin-variable</p>										
v:numbersize	<p>Number of bits in a Number. This is normally 64, but on some systems it may be 32.</p>	<p>v:numbersize    numbersize-variable</p>										
v:oldfiles	<p>List of file names that is loaded from the <code>viminfo</code> file on startup. These are the files that Vim remembers marks for. The length of the List is limited by the ' argument of the <code>'viminfo'</code> option (default is 100). When the <code>viminfo</code> file is not used the List is empty. Also see <code>:oldfiles</code> and <code>c_#&lt;</code>. The List can be modified, but this has no effect on what is stored in the <code>viminfo</code> file later. If you use values other than String this will cause trouble. {only when compiled with the  +viminfo  feature}</p>	<p>v:oldfiles    oldfiles-variable</p>										
v:option_new	<p>New value of the option. Valid while executing an <code>OptionSet</code> autocommand.</p>	<p>v:option_new</p>										
v:option_old	<p>Old value of the option. Valid while executing an <code>OptionSet</code> autocommand. Depending on the command used for setting and the kind of option this is either the local old value or the global old value.</p>	<p>v:option_old</p>										
v:option_oldlocal	<p>Old local value of the option. Valid while executing an <code>OptionSet</code> autocommand.</p>	<p>v:option_oldlocal</p>										
v:option_oldglobal	<p>Old global value of the option. Valid while executing an <code>OptionSet</code> autocommand.</p>	<p>v:option_oldglobal</p>										
v:option_type	<p>Scope of the set command. Valid while executing an <code>OptionSet</code> autocommand. Can be either "global" or "local"</p>	<p>v:option_type</p>										
v:option_command	<p>Command used to set the option. Valid while executing an <code>OptionSet</code> autocommand.</p> <table border="0" style="margin-left: 2em;"> <tr> <td style="padding-right: 1em;">value</td> <td>option was set via</td> </tr> <tr> <td>"setlocal"</td> <td>:setlocal or ":let l:xxx"</td> </tr> <tr> <td>"setglobal"</td> <td>:setglobal or ":let g:xxx"</td> </tr> <tr> <td>"set"</td> <td>:set or :let</td> </tr> <tr> <td>"modeline"</td> <td>modeline</td> </tr> </table>	value	option was set via	"setlocal"	:setlocal or ":let l:xxx"	"setglobal"	:setglobal or ":let g:xxx"	"set"	:set or :let	"modeline"	modeline	<p>v:option_command</p>
value	option was set via											
"setlocal"	:setlocal or ":let l:xxx"											
"setglobal"	:setglobal or ":let g:xxx"											
"set"	:set or :let											
"modeline"	modeline											
v:operator	<p>The last operator given in Normal mode. This is a single character except for commands starting with &lt;g&gt; or &lt;z&gt;, in which case it is two characters. Best used alongside <code>v:prevcount</code> and <code>v:register</code>. Useful if you want to cancel Operator-pending mode and then use the operator, e.g.:</p>	<p>v:operator    operator-variable</p>										

`:omap 0 <Esc>:call MyMotion(v:operator)<CR>`

The value remains set until another operator is entered, thus don't expect it to be empty.  
`v:operator` is not set for `:delete` , `:yank` or other Ex commands.  
 Read-only.

`v:prevcnt`      `prevcnt-variable`

`v:prevcnt`      The count given for the last but one Normal mode command. This is the `v:count` value of the previous command. Useful if you want to cancel Visual or Operator-pending mode and then use the count, e.g.:  
`:vmap % <Esc>:call MyFilter(v:prevcnt)<CR>`  
 Read-only.

`v:profiling`      `profiling-variable`

`v:profiling`      Normally zero. Set to one after using `":profile start"`. See `profiling` .

`v:progrname`      `progrname-variable`

`v:progrname`      Contains the name (with path removed) with which Vim was invoked. Allows you to do special initialisations for `view` , `evim` etc., or any other name you might symlink to Vim.  
 Read-only.

`v:progrpath`      `progrpath-variable`

`v:progrpath`      Contains the command with which Vim was invoked, in a form that when passed to the shell will run the same Vim executable as the current one (if `$PATH` remains unchanged). Useful if you want to message a Vim server using a `--remote-expr` .  
 To get the full path use:  
`echo exepath(v:progrpath)`  
 If the command has a relative path it will be expanded to the full path, so that it still works after ``:cd``. Thus starting `"/vim"` results in `"/home/user/path/to/vim/src/vim"`.  
 On Linux and other systems it will always be the full path.  
 On Mac it may just be `"vim"` and using `exepath()` as mentioned above should be used to get the full path.  
 On MS-Windows the executable may be called `"vim.exe"`, but the `".exe"` is not added to `v:progrpath`.  
 Read-only.

`v:python3_version`      `python3-version-variable`

`v:python3_version`      Version of Python 3 that Vim was built against. When Python is loaded dynamically ( `python-dynamic` ), this version should exactly match the Python library up to the minor version (e.g. 3.10.2 and 3.10.3 are compatible as the minor version is "10", whereas 3.9.4 and 3.10.3 are not compatible). When `python-stable-abi` is used, this will be the minimum Python version that you can use instead. (e.g. if `v:python3_version` indicates 3.9, you can use 3.9, 3.10, or anything above).

This number is encoded as a hex number following Python ABI versioning conventions. Do the following to have a human-readable full version in hex:

```
echo printf("%08X", v:python3_version)
```

You can obtain only the minor version by doing:

```
echo and(v:python3_version>>16,0xff)
```

Read-only.

- v:register** v:register register-variable  
The name of the register in effect for the current normal mode command (regardless of whether that command actually used a register). Or for the currently executing normal mode mapping (use this in custom commands that take a register). If none is supplied it is the default register '', unless **'clipboard'** contains "unnamed" or "unnamedplus", then it is '\*' or '+'.  
Also see `getreg()` and `setreg()`.
- v:scrollstart** v:scrollstart scrollstart-variable  
String describing the script or function that caused the screen to scroll up. It's only set when it is empty, thus the first reason is remembered. It is set to "Unknown" for a typed command.  
This can be used to find out why your script causes the hit-enter prompt.
- v:servername** v:servername servername-variable  
The resulting registered `client-server-name` if any.  
Read-only.
- v:searchforward** v:searchforward searchforward-variable  
Search direction: 1 after a forward search, 0 after a backward search. It is reset to forward when directly setting the last search pattern, see `quote/`.  
**Note** that the value is restored when returning from a function. `function-search-undo`.  
Read-write.
- v:shell\_error** v:shell\_error shell\_error-variable  
Result of the last shell command. When non-zero, the last shell command had an error. When zero, there was no problem. This only works when the shell returns the error code to Vim. The value -1 is often used when the command could not be executed. Read-only.  
Example:  

```
:!mv foo bar
:if v:shell_error
: echo 'could not rename "foo" to "bar"!
:endif
```

  
"shell\_error" also works, for backwards compatibility, unless `scriptversion` is 3 or higher.
- v:sizeofint sizeofint-variable

`v:sizeofint` Number of bytes in an int. Depends on how Vim was compiled. This is only useful for deciding whether a test will give the expected result.

`v:sizeoflong` Number of bytes in a long. Depends on how Vim was compiled. This is only useful for deciding whether a test will give the expected result.

`v:sizeofpointer` Number of bytes in a pointer. Depends on how Vim was compiled. This is only useful for deciding whether a test will give the expected result.

`v:stacktrace` The stack trace of the exception most recently caught and not finished. Refer to `getstacktrace()` for the structure of stack trace. See also `v:exception`, `v:throwpoint`, and `throw-variables`.

`v:statusmsg` Last given status message. It's allowed to set this variable.

`v:swapname` Only valid when executing `SwapExists` autocommands: Name of the swap file found. Read-only.

`v:swapchoice` `SwapExists` autocommands can set this to the selected choice for handling an existing swap file:

'o'	Open read-only
'e'	Edit anyway
'r'	Recover
'd'	Delete swapfile
'q'	Quit
'a'	Abort

The value should be a single-character string. An empty value results in the user being asked, as would happen when there is no `SwapExists` autocommand. The default is empty.

`v:swapcommand` Normal mode command to be executed after a file has been opened. Can be used for a `SwapExists` autocommand to have another Vim open the file and jump to the right place. For example, when jumping to a tag the value is `":tag tagname\r"`. For `":edit +cmd file"` the value is `":cmd\r"`.

`v:t_bool` Value of `Boolean` type. Read-only. See: `type()`

`v:t_channel` Value of `Channel` type. Read-only. See: `type()`

`v:t_dict` Value of `Dictionary` type. Read-only. See: `type()`

`v:t_float` Value of `Float` type. Read-only. See: `type()`  
`v:t_func` Value of `Funcref` type. Read-only. See: `type()`  
`v:t_job` Value of `Job` type. Read-only. See: `type()`  
`v:t_list` Value of `List` type. Read-only. See: `type()`  
`v:t_none` Value of `None` type. Read-only. See: `type()`  
`v:t_number` Value of `Number` type. Read-only. See: `type()`  
`v:t_string` Value of `String` type. Read-only. See: `type()`  
`v:t_blob` Value of `Blob` type. Read-only. See: `type()`  
`v:t_class` Value of `class` type. Read-only. See: `type()`  
`v:t_object` Value of `object` type. Read-only. See: `type()`  
`v:t_typealias` Value of `typealias` type. Read-only. See: `type()`  
`v:t_enum` Value of `enum` type. Read-only. See: `type()`  
`v:t_enumvalue` Value of `enumvalue` type. Read-only. See: `type()`

`v:termresponse` The escape sequence returned by the terminal for the `t_RV` termcap entry. It is set when Vim receives an escape sequence that starts with ESC [ or CSI, then '>' or '?' and ends in a 'c', with only digits and ';' in between. When this option is set, the TermResponse autocommand event is fired, so that you can react to the response from the terminal. The TermResponseAll event is also fired, with `<amatch>` set to "version". You can use `terminalprops()` to see what Vim figured out about the terminal. The response from a new xterm is: "`<Esc>[> Pp ; Pv ; Pc c`". Pp is the terminal type: 0 for vt100 and 1 for vt220. Pv is the patch level (since this was introduced in patch 95, it's always 95 or higher). Pc is always zero. If Pv is 141 or higher then Vim will try to request terminal codes. This only works with xterm `xterm-codes`.  
{only when compiled with `|+termresponse|` feature}

`v:termblinkresp` The escape sequence returned by the terminal for the `t_RC` termcap entry. This is used to find out whether the terminal cursor is blinking. This is used by `term_getcursor()`. When this option is set, the TermResponseAll autocommand event is fired, with `<amatch>` set to "cursorblink".

`v:termstyleresp` The escape sequence returned by the terminal for the `t_RS` termcap entry. This is used to find out what the shape of the

cursor is. This is used by `term_getcursor()` . When this option is set, the TermResponseAll autocommand event is fired, with `<amatch>` set to "cursorshape".

- `v:termrbgresp` `v:termrbgresp`  
The escape sequence returned by the terminal for the `t_RB` termcap entry. This is used to find out what the terminal background color is; see '`background`'. When this option is set, the TermResponseAll autocommand event is fired, with `<amatch>` set to "background".
- `v:termrfgresp` `v:termrfgresp`  
The escape sequence returned by the terminal for the `t_RF` termcap entry. This is used to find out what the terminal foreground color is. When this option is set, the TermResponseAll autocommand event is fired, with `<amatch>` set to "foreground".
- `v:termu7resp` `v:termu7resp`  
The escape sequence returned by the terminal for the `t_u7` termcap entry. This is used to find out what the terminal does with ambiguous width characters, see '`ambiwidth`'. When this option is set, the TermResponseAll autocommand event is fired, with `<amatch>` set to "ambiguouswidth".
- `v:testing` `v:testing` `testing-variable`  
Must be set before using ``test_garbagecollect_now()``. Also, when set certain error messages won't be shown for 2 seconds. (e.g. "`'dictionary'` option is empty")
- `v:this_session` `v:this_session` `this_session-variable`  
Full filename of the last loaded or saved session file. See `:mksession` . It is allowed to set this variable. When no session file has been saved, this variable is empty. "this\_session" also works, for backwards compatibility, unless `scriptversion` is 3 or higher
- `v:throwpoint` `v:throwpoint` `throwpoint-variable`  
The point where the exception most recently caught and not finished was thrown. Not set when commands are typed. See also `v:exception` , `v:stacktrace` , and `throw-variables` .  
Example:  

```
:try
: throw "oops"
:catch /.*/
: echo "Exception from" v:throwpoint
:endtry
```

  
Output: "Exception from test.vim, line 2"
- `v:true` `v:true` `true-variable`  
A Number with value one. Used to put "true" in JSON. See `json_encode()` .  
When used as a string this evaluates to "v:true".  

```
echo v:true
```

	<code>v:true</code>	That is so that <code>eval()</code> can parse the string back to the same value. Read-only. In <code>Vim9</code> script "true" can be used which has a boolean type.
<code>v:val</code>	<code>v:val</code> <code>val-variable</code>	Value of the current item of a <code>List</code> or <code>Dictionary</code> . Only valid while evaluating the expression used with <code>map()</code> and <code>filter()</code> . Read-only.
<code>v:version</code>	<code>v:version</code> <code>version-variable</code>	Version number of Vim: Major version number times 100 plus minor version number. Version 5.0 is 500. Version 5.1 is 501. Read-only. "version" also works, for backwards compatibility, unless <code>scriptversion</code> is 3 or higher. Use <code>has()</code> to check if a certain patch was included, e.g.: <code>if has("patch-7.4.123")</code> <b>Note</b> that patch numbers are specific to the version, thus both version 5.0 and 5.1 may have a patch 123, but these are completely different.
<code>v:versionlong</code>	<code>v:versionlong</code> <code>versionlong-variable</code>	Like <code>v:version</code> , but also including the patchlevel in the last four digits. Version 8.1 with patch 123 has value 8010123. This can be used like this: <code>if v:versionlong &gt;= 8010123</code> However, if there are gaps in the list of patches included this will not work well. This can happen if a recent patch was included into an older version, e.g. for a security fix. Use the <code>has()</code> function to make sure the patch is actually included.
<code>v:vim_did_enter</code>	<code>v:vim_did_enter</code> <code>vim_did_enter-variable</code>	Zero until most of startup is done. It is set to one just before <code>VimEnter</code> autocommands are triggered.
<code>v:warningmsg</code>	<code>v:warningmsg</code> <code>warningmsg-variable</code>	Last given warning message. It's allowed to set this variable.
<code>v:windowid</code>	<code>v:windowid</code> <code>windowid-variable</code>	When any X11/Wayland based GUI is running or when running in a terminal and Vim connects to the X server ( <code>-X</code> ) this will be set to the window ID. When an MS-Windows GUI is running this will be set to the window handle. Otherwise the value is zero. <b>Note:</b> for windows inside Vim use <code>winnr()</code> or <code>win_getid()</code> , see <code>window-ID</code> .

=====  
4. Builtin Functions `functions`

See `function-list` for a list grouped by what the function is used for.

The alphabetic list of all builtin functions and details are in a separate

help file: [builtin-functions](#) .

---

## 5. Defining functions

[user-functions](#)

New functions can be defined. These can be called just like builtin functions. The function takes arguments, executes a sequence of Ex commands and can return a value.

You can find most information about defining functions in [userfunc.txt](#) . For Vim9 functions, which execute much faster, support type checking and more, see [vim9.txt](#) .

---

## 6. Curly braces names

[curly-braces-names](#)

In most places where you can use a variable, you can use a "curly braces name" variable. This is a regular variable name with one or more expressions wrapped in braces {} like this:

```
my_{adjective}_variable
```

This only works in legacy Vim script, not in [Vim9](#) script.

When Vim encounters this, it evaluates the expression inside the braces, puts that in place of the expression, and re-interprets the whole as a variable name. So in the above example, if the variable "adjective" was set to "noisy", then the reference would be to "my\_noisy\_variable", whereas if "adjective" was set to "quiet", then it would be to "my\_quiet\_variable".

One application for this is to create a set of variables governed by an option value. For example, the statement

```
echo my_{&background}_message
```

would output the contents of "my\_dark\_message" or "my\_light\_message" depending on the current value of **'background'**.

You can use multiple brace pairs:

```
echo my_{adverb}_{adjective}_message
```

..or even nest them:

```
echo my_{ad{end_of_word}}_message
```

where "end\_of\_word" is either "verb" or "jective".

However, the expression inside the braces must evaluate to a valid single variable name, e.g. this is invalid:

```
:let foo='a + b'
:echo c{foo}d
```

.. since the result of expansion is "ca + bd", which is not a variable name.

[curly-braces-function-names](#)

You can call and define functions by an evaluated name in a similar way.

Example:

```
:let func_end='whizz'
:call my_func_{func_end}(parameter)
```

This would call the function "my\_func\_whizz(parameter)".

This does NOT work:

```
:let i = 3
:let @{i} = '' " error
:echo @{i} " error
```

---

## 7. Commands

expression-commands

**Note:** in Vim9 script `:let` is not used. `:var` is used for variable declarations and assignments do not use a command. vim9-declaration

```
:let {var-name} = {expr1} :let E18
 Set internal variable {var-name} to the result of the
 expression {expr1}. The variable will get the type
 from the {expr}. If {var-name} didn't exist yet, it
 is created.
```

```
:let {var-name}[{idx}] = {expr1} E689 E1141
 Set a list item to the result of the expression
 {expr1}. {var-name} must refer to a list and {idx}
 must be a valid index in that list. For nested list
 the index can be repeated.
 This cannot be used to add an item to a List .
 This cannot be used to set a byte in a String. You
 can do that like this:
 :let var = var[0:2] .. 'X' .. var[4:]
 When {var-name} is a Blob then {idx} can be the
 length of the blob, in which case one byte is
 appended.
```

```
:let {var-name}[{idx1}:{idx2}] = {expr1} E711 E719 E1165 E1166 E1183
 E708 E709 E710
 Set a sequence of items in a List to the result of
 the expression {expr1}, which must be a list with the
 correct number of items.
 {idx1} can be omitted, zero is used instead.
 {idx2} can be omitted, meaning the end of the list.
 When the selected range of items is partly past the
 end of the list, items will be added.
```

```
:let {var} += {expr1} Like ":let {var} = {var} + {expr1}".
:let {var} -= {expr1} Like ":let {var} = {var} - {expr1}".
:let {var} *= {expr1} Like ":let {var} = {var} * {expr1}".
:let {var} /= {expr1} Like ":let {var} = {var} / {expr1}".
:let {var} %= {expr1} Like ":let {var} = {var} % {expr1}".
:let {var} .= {expr1} Like ":let {var} = {var} . {expr1}".
:let {var} .= {expr1} Like ":let {var} = {var} .. {expr1}".
:let+= :let-= :letstar= :let/= :let%=
:let.= :let..= E734 E985 E1019
These fail if {var} was not set yet and when the type
of {var} and {expr1} don't fit the operator.
`+=` modifies a List or a Blob in-place instead of
```

creating a new one.  
`.` is not supported with Vim script version 2 and later, see [vimscript-version](#) .

`:let ${env-name} = {expr1}` `:let-environment` `:let-$`  
Set environment variable `{env-name}` to the result of the expression `{expr1}`. The type is always String.

On some systems making an environment variable empty causes it to be deleted. Many systems do not make a difference between an environment variable that is not set and an environment variable that is empty.

`:let ${env-name} .= {expr1}`  
Append `{expr1}` to the environment variable `{env-name}`. If the environment variable didn't exist yet this works like "=".

`:let @{reg-name} = {expr1}` `:let-register` `:let-@`  
Write the result of the expression `{expr1}` in register `{reg-name}`. `{reg-name}` must be a single letter, and must be the name of a writable register (see [registers](#) ). "@" can be used for the unnamed register, "@/" for the search pattern. If the result of `{expr1}` ends in a <CR> or <NL>, the register will be linewise, otherwise it will be set to characterwise. This can be used to clear the last search pattern:  
`:let @/ = ""`  
This is different from searching for an empty string, that would match everywhere.

`:let @{reg-name} .= {expr1}`  
Append `{expr1}` to register `{reg-name}`. If the register was empty it's like setting it to `{expr1}`.

`:let &{option-name} = {expr1}` `:let-option` `:let-&`  
Set option `{option-name}` to the result of the expression `{expr1}`. A String or Number value is always converted to the type of the option. For an option local to a window or buffer the effect is just like using the `:set` command: both the local value and the global value are changed.  
Example:

```
:let &path = &path .. ',/usr/local/include'
```

This also works for terminal codes in the form `t_xx`. But only for alphanumerical names. Example:

```
:let &t_k1 = "\<Esc>[234;"
```

When the code does not exist yet it will be created as a terminal key code, there is no error.

`:let &{option-name} .= {expr1}`  
For a string option: Append `{expr1}` to the value.

Does not insert a comma like `:set+=` .

```
:let &{option-name} += {expr1}
:let &{option-name} -= {expr1}
```

For a number or boolean option: Add or subtract `{expr1}`.

```
:let &l:{option-name} = {expr1}
:let &l:{option-name} .= {expr1}
:let &l:{option-name} += {expr1}
:let &l:{option-name} -= {expr1}
```

Like above, but only set the local value of an option (if there is one). Works like `:setlocal` .

```
:let &g:{option-name} = {expr1}
:let &g:{option-name} .= {expr1}
:let &g:{option-name} += {expr1}
:let &g:{option-name} -= {expr1}
```

Like above, but only set the global value of an option (if there is one). Works like `:setglobal` .

```
:let [{name1}, {name2}, ...] = {expr1} E1093
:let-unpack E687 E688
```

`{expr1}` must evaluate to a `List` . The first item in the list is assigned to `{name1}`, the second item to `{name2}`, etc.

The number of names must match the number of items in the `List` .

Each name can be one of the items of the `":let"` command as mentioned above.

Example:

```
:let [s, item] = GetItem(s)
```

Detail: `{expr1}` is evaluated first, then the assignments are done in sequence. This matters if `{name2}` depends on `{name1}`. Example:

```
:let x = [0, 1]
:let i = 0
:let [i, x[i]] = [1, 2]
:echo x
```

The result is `[0, 2]`.

```
:let [{name1}, {name2}, ...] .= {expr1}
:let [{name1}, {name2}, ...] += {expr1}
:let [{name1}, {name2}, ...] -= {expr1}
```

Like above, but append/add/subtract the value for each `List` item.

```
:let [{name}, ..., ; {lastname}] = {expr1} E452
```

Like `:let-unpack` above, but the `List` may have more items than there are names. A list of the remaining items is assigned to `{lastname}`. If there are no remaining items `{lastname}` is set to an empty list.

Example:

```
:let [a, b; rest] = ["aval", "bval", 3, 4]
```

```
:let [{name}, ..., ; {lastname}] .= {expr1}
:let [{name}, ..., ; {lastname}] += {expr1}
:let [{name}, ..., ; {lastname}] -= {expr1}
```

Like above, but append/add/subtract the value for each `List` item.

```

 :let=<< :let-heredoc
 E990 E991 E172 E221 E1145
:let {var-name} =<< [trim] [eval] {endmarker}
text...
text...
{endmarker}
```

Set internal variable `{var-name}` to a `List` containing the lines of text bounded by the string `{endmarker}`.

If "eval" is not specified, then each line of text is used as a `literal-string`, except that single quotes does not need to be doubled.

If "eval" is specified, then any Vim expression in the form `{expr}` is evaluated and the result replaces the expression, like with `interpolated-string`.

Example where \$HOME is expanded:

```
let lines =<< trim eval END
 some text
 See the file {$HOME}/.vimrc
 more text
END
```

There can be multiple Vim expressions in a single line but an expression cannot span multiple lines. If any expression evaluation fails, then the assignment fails.

`{endmarker}` must not contain white space.

`{endmarker}` cannot start with a lower case character.

The last line should end only with the `{endmarker}` string without any other character. Watch out for white space after `{endmarker}`!

Without "trim" any white space characters in the lines of text are preserved. If "trim" is specified before `{endmarker}`, then indentation is stripped so you can do:

```
let text =<< trim END
 if ok
 echo 'done'
 endif
END
```

Results in: ["if ok", " echo 'done'", "endif"]

The marker must line up with "let" and the indentation of the first line is removed from all the text lines. Specifically: all the leading indentation exactly matching the leading indentation of the first non-empty text line is stripped from the input lines. All leading indentation exactly matching the leading

indentation before ``let`` is stripped from the line containing `{endmarker}`. Note that the difference between space and tab matters here.

If `{var-name}` didn't exist yet, it is created. Cannot be followed by another command, but can be followed by a comment.

To avoid line continuation to be applied, consider adding 'C' to `'cptions'`:

```
set cpo+=C
let var =<< END
 \ leading backslash
END
set cpo-=C
```

Examples:

```
let var1 =<< END
Sample text 1
 Sample text 2
Sample text 3
END

let data =<< trim DATA
 1 2 3 4
 5 6 7 8
DATA

let code =<< trim eval CODE
 let v = {10 + 20}
 let h = "{$HOME}"
 let s = "{Str1()} abc {Str2()}"
 let n = {MyFunc(3, 4)}
CODE
```

`:let {var-name} ..` List the value of variable `{var-name}`. Multiple variable names may be given. Special names recognized here: E121  
E738

- g: global variables
- b: local buffer variables
- w: local window variables
- t: local tab page variables
- s: script-local variables
- l: local function variables
- v: Vim variables.

This does not work in Vim9 script. [vim9-declaration](#)

`:let` List the values of all variables. The type of the variable is indicated before the value:

```
<nothing> String
Number
* Funcref
```

This does not work in Vim9 script. [vim9-declaration](#)

```
:unl[et][!] {name} ...
```

:unlet :unl E108 E795 E1081

Remove the internal variable {name}. Several variable names can be given, they are all removed. The name may also be a List or Dictionary item. With [!] no error message is given for non-existing variables.

One or more items from a List can be removed:

```
:unlet list[3] " remove fourth item
:unlet list[3:] " remove fourth item to last
```

One item from a Dictionary can be removed at a time:

```
:unlet dict['two']
:unlet dict.two
```

This is especially useful to clean up used global variables and script-local variables (these are not deleted when the script ends). Function-local variables are automatically deleted when the function ends.

In Vim9 script variables declared in a function or script cannot be removed.

```
:unl[et] ${env-name} ...
```

:unlet-environment :unlet-\$

Remove environment variable {env-name}. Can mix {name} and \${env-name} in one :unlet command. No error message is given for a non-existing variable, also without !. If the system does not support deleting an environment variable, it is made empty.

:cons :const E1018

```
:cons[t] {var-name} = {expr1}
:cons[t] [{name1}, {name2}, ...] = {expr1}
:cons[t] [{name}, ..., ; {lastname}] = {expr1}
:cons[t] {var-name} =<< [trim] [eval] {marker}
text...
text...
{marker}
```

Similar to :let , but additionally lock the variable after setting the value. This is the same as locking the variable with :lockvar just after :let , thus:

```
:const x = 1
```

is equivalent to:

```
:let x = 1
:lockvar! x
```

**NOTE:** in Vim9 script `:const` works differently, see [vim9-const](#)

This is useful if you want to make sure the variable is not modified. If the value is a List or Dictionary literal then the items also cannot be changed:

```
const ll = [1, 2, 3]
let ll[1] = 5 " Error!
```

Nested references are not locked:

```
let lvar = ['a']
const lconst = [0, lvar]
```

```

let lconst[0] = 2 " Error!
let lconst[1][0] = 'b' " OK
E995

```

It is an error to specify an existing variable with `:const` .

```

:let x = 1
:const x = 1 " Error!
E996

```

**Note** that environment variables, option values and register values cannot be used here, since they cannot be locked.

```

:cons[t]
:cons[t] {var-name}

```

If no argument is given or only `{var-name}` is given, the behavior is the same as `:let` .

```

:lockv[ar][!] [depth] {name} ... :lockvar :lockv

```

Lock the internal variable `{name}`. Locking means that it can no longer be changed (until it is unlocked). A locked variable can be deleted:

```

:lockvar v
:let v = 'asdf' " fails!
:unlock v " works

```

E741 E940 E1118 E1119 E1120 E1121 E1122

If you try to change a locked variable you get an error message: "E741: Value is locked: `{name}`".

If you try to lock or unlock a built-in variable you get an error message: "E940: Cannot lock or unlock variable `{name}`".

`[depth]` is relevant when locking a `List` or `Dictionary` . It specifies how deep the locking goes:

- 0 Lock the variable `{name}` but not its value.
- 1 Lock the `List` or `Dictionary` itself, cannot add or remove items, but can still change their values.
- 2 Also lock the values, cannot change the items. If an item is a `List` or `Dictionary` , cannot add or remove items, but can still change the values.
- 3 Like 2 but for the `List` / `Dictionary` in the `List` / `Dictionary` , one level deeper.

The default `[depth]` is 2, thus when `{name}` is a `List` or `Dictionary` the values cannot be changed.

Example with `[depth]` 0:

```

let mylist = [1, 2, 3]
lockvar 0 mylist
let mylist[0] = 77 " OK
call add(mylist, 4) " OK

```

```
let mylist = [7, 8, 9] " Error!
```

E743

For unlimited depth use [!] and omit [depth].  
However, there is a maximum depth of 100 to catch loops.

Note that when two variables refer to the same List and you lock one of them, the List will also be locked when used through the other variable.

Example:

```
:let l = [0, 1, 2, 3]
:let cl = l
:lockvar l
:let cl[1] = 99 " won't work!
```

You may want to make a copy of a list to avoid this.  
See `deepcopy()` .

E1391 E1392

Locking and unlocking object and class variables is currently NOT supported.

```
:unlo[ckvar][!] [depth] {name} ... :unlockvar :unlo E1246
Unlock the internal variable {name}. Does the
opposite of :lockvar .
```

If {name} does not exist:

- In Vim9 script an error is given.
- In legacy script this is silently ignored.

```
:if {expr1} :if :end :endif :en E171 E579 E580
:en[dif]
```

Execute the commands until the next matching `:else`` or `:endif`` if {expr1} evaluates to non-zero. Although the short forms work, it is recommended to always use `:endif`` to avoid confusion and to make auto-indenting work properly.

From Vim version 4.5 until 5.0, every Ex command in between the `:if`` and `:endif`` is ignored. These two commands were just to allow for future expansions in a backward compatible way. Nesting was allowed. Note that any `:else`` or `:elseif`` was ignored, the `:else`` part was not executed either.

You can use this to remain compatible with older versions:

```
:if version >= 500
: version-5-specific-commands
:endif
```

The commands still need to be parsed to find the `:endif``. Sometimes an older Vim has a problem with a new command. For example, `:silent`` is recognized as a `:substitute`` command. In that case `:execute`` can avoid problems:

```

:if version >= 600
: execute "silent 1,$delete"
:endif

```

In Vim9 script `:endif` cannot be shortened, to improve script readability.

**NOTE:** The `:append` and `:insert` commands don't work properly in between `:if` and `:endif`.

```

:el[se]

```

`:else` `:el` E581 E583

Execute the commands until the next matching `:else` or `:endif` if they previously were not being executed.

In Vim9 script `:else` cannot be shortened, to improve script readability.

```

:elsei[f] {expr1}

```

`:elseif` `:elsei` E582 E584

Short for `:else` `:if`, with the addition that there is no extra `:endif`.

In Vim9 script `:elseif` cannot be shortened, to improve script readability.

```

:wh[ile] {expr1}
:endw[hile]

```

`:while` `:endwhile` `:wh` `:endw`  
E170 E585 E588 E733

Repeat the commands between `:while` and `:endwhile`, as long as `{expr1}` evaluates to non-zero.

When an error is detected from a command inside the loop, execution continues after the `:endwhile`.

Example:

```

:let lnum = 1
:while lnum <= line("$")
: call FixLine(lnum)
: let lnum = lnum + 1
:endwhile

```

In Vim9 script `:while` and `:endwhile` cannot be shortened, to improve script readability.

**NOTE:** The `:append` and `:insert` commands don't work properly inside a `:while` and `:for` loop.

```

:for {var} in {object}
:endfo[r]

```

`:for` E690 E732  
`:endfo` `:endfor`

Repeat the commands between `:for` and `:endfor` for each item in `{object}`. `{object}` can be a `List`, a `Blob` or a `String`. E1177

Variable `{var}` is set to the value of each item.

In Vim9 script the loop variable must not have been declared yet, unless when it is a global/window/tab/buffer variable.

When an error is detected for a command inside the loop, execution continues after the `:endfor`.

Changing `{object}` inside the loop affects what items

are used. Make a copy if this is unwanted:  
`:for item in copy(mylist)`

When `{object}` is a `List` and not making a copy, in legacy script Vim stores a reference to the next item in the `List` before executing the commands with the current item. Thus the current item can be removed without effect. Removing any later item means it will not be found. Thus the following example works (an inefficient way to make a `List` empty):

```
for item in mylist
 call remove(mylist, 0)
endfor
```

**Note** that reordering the `List` (e.g., with `sort()` or `reverse()`) may have unexpected effects.

In `Vim9` script the index is used. If an item before the current one is deleted the next item will be skipped.

When `{object}` is a `Blob`, Vim always makes a copy to iterate over. Unlike with `List`, modifying the `Blob` does not affect the iteration.

When `{object}` is a `String` each item is a string with one character, plus any combining characters.

In `Vim9` script `:endfor` cannot be shortened, to improve script readability.

```
:for [{var1}, {var2}, ...] in {listlist}
:endfo[r]
```

E1140

Like `:for` above, but each item in `{listlist}` must be a list, of which each item is assigned to `{var1}`, `{var2}`, etc. Example:

```
:for [lnum, col] in [[1, 3], [2, 5], [3, 8]]
 :echo getline(lnum)[col]
:endifor
```

`:continue` `:con` E586

```
:con[ti]ue]
```

When used inside a `:while` or `:for` loop, jumps back to the start of the loop.

If it is used after a `:try` inside the loop but before the matching `:finally` (if present), the commands following the `:finally` up to the matching `:endtry` are executed first. This process applies to all nested `:try`'s inside the loop. The outermost `:endtry` then jumps back to the start of the loop.

In `Vim9` script `:cont` is the shortest form, to improve script readability.

`:break` `:brea` E587

```
:brea[k]
```

When used inside a `:while` or `:for` loop, skips to the command after the matching `:endwhile` or `:endifor`.

If it is used after a `:try` inside the loop but before the matching `:finally` (if present), the commands following the `:finally` up to the matching `:endtry` are executed first. This process applies to all nested `:try`'s inside the loop. The outermost `:endtry` then jumps to the command after the loop.

In Vim9 script `:break` cannot be shortened, to improve script readability.

```
:try :try :endt :endtry
 E600 E601 E602 E1032
:endt[ry]
```

Change the error handling for the commands between `:try` and `:endtry` including everything being executed across `:source` commands, function calls, or autocommand invocations.

When an error or interrupt is detected and there is a `:finally` command following, execution continues after the `:finally`. Otherwise, or when the `:endtry` is reached thereafter, the next (dynamically) surrounding `:try` is checked for a corresponding `:finally` etc. Then the script processing is terminated. Whether a function definition has an "abort" argument does not matter. Example:

```
try | call Unknown() | finally | echomsg "cleanup" | endtry
echomsg "not reached"
```

Moreover, an error or interrupt (dynamically) inside `:try` and `:endtry` is converted to an exception. It can be caught as if it were thrown by a `:throw` command (see `:catch`). In this case, the script processing is not terminated.

The value "Vim:Interrupt" is used for an interrupt exception. An error in a Vim command is converted to a value of the form "Vim({command}):{errmsg}", other errors are converted to a value of the form "Vim:{errmsg}". `{command}` is the full command name, and `{errmsg}` is the message that is displayed if the error exception is not caught, always beginning with the error number.

Examples:

```
try | sleep 100 | catch /^Vim:Interrupt$/ | endtry
try | edit | catch /^Vim(edit):E\d\+$/ | echo "error" | endtry
```

In Vim9 script `:endtry` cannot be shortened, to improve script readability.

```
:cat[ch] /{pattern}/ :cat :catch
 E603 E604 E605 E654 E1033
```

The following commands until the next `:catch`, `:finally`, or `:endtry` that belongs to the same

`:try` as the `:catch` are executed when an exception matching {pattern} is being thrown and has not yet been caught by a previous `:catch`. Otherwise, these commands are skipped.

When {pattern} is omitted all errors are caught.

Examples:

```
:catch /^Vim:Interrupt$/ " catch interrupts (CTRL-C)
:catch /^Vim%\%((\a+)\)\|=E/ " catch all Vim errors
:catch /^Vim%\%((\a+)\)\|=:/ " catch errors and interrupts
:catch /^Vim(write):/ " catch all errors in :write
:catch /^Vim%\%((\a+)\)\|=E123:/ " catch error E123
:catch /my-exception/ " catch user exception
:catch /.*/ " catch everything
:catch " same as /.*/
```

Another character can be used instead of / around the {pattern}, so long as it does not have a special meaning (e.g., '|' or '"') and doesn't occur inside {pattern}. E1067

Information about the exception is available in `v:exception`. Also see `throw-variables`.

**NOTE:** It is not reliable to `:catch` the TEXT of an error message because it may vary in different locales.

In `Vim9` script `:catch` cannot be shortened, to improve script readability.

`:fina[lly]`

`:fina` `:finally` E606 E607

The following commands until the matching `:endtry` are executed whenever the part between the matching `:try` and the `:finally` is left: either by falling through to the `:finally` or by a `:continue`, `:break`, `:finish`, or `:return`, or by an error or interrupt or exception (see `:throw`).

In `Vim9` script `:finally` cannot be shortened, to improve script readability and avoid confusion with `:final`.

`:th[ow] {expr1}`

`:th` `:throw` E608 E1129

The {expr1} is evaluated and thrown as an exception. If the `:throw` is used after a `:try` but before the first corresponding `:catch`, commands are skipped until the first `:catch` matching {expr1} is reached. If there is no such `:catch` or if the `:throw` is used after a `:catch` but before the `:finally`, the commands following the `:finally` (if present) up to the matching `:endtry` are executed. If the `:throw` is after the `:finally`, commands up to the `:endtry` are skipped. At the `:endtry`, this process applies again for the next dynamically surrounding `:try` (which may be found in a calling function or sourcing script), until a matching `:catch` has been found. If the exception is not caught, the command processing

is terminated.

Example:

```
:try | throw "oops" | catch /^oo/ | echo "caught" | endtry
```

Note that "catch" may need to be on a separate line for when an error causes the parsing to skip the whole line and not see the "|" that separates the commands.

In Vim9 script `:throw` cannot be shortened, to improve script readability.

`:ec[ho] {expr1} ..` `:ec` `:echo`  
Echoes each {expr1}, with a space in between. The first {expr1} starts on a new line. Also see `:comment`. Use "\n" to start a new line. Use "\r" to move the cursor to the first column. Uses the highlighting set by the `:echohl` command. Cannot be followed by a comment. Example:

```
:echo "the value of 'shell' is" &shell
```

`:echo-redraw`

A later redraw may make the message disappear again. And since Vim mostly postpones redrawing until it's finished with a sequence of commands this happens quite often. To avoid that a command from before the `:echo` causes a redraw afterwards (redraws are often postponed until you type something), force a redraw with the `:redraw` command. Example:

```
:new | redraw | echo "there is a new window"
```

`:echon {expr1} ..` `:echon`  
Echoes each {expr1}, without anything added. Also see `:comment`. Uses the highlighting set by the `:echohl` command. Cannot be followed by a comment. Example:

```
:echon "the value of 'shell' is " &shell
```

Note the difference between using `:echo`, which is a Vim command, and `:!echo`, which is an external shell command:

```
:!echo % --> filename
```

The arguments of "!" are expanded, see `:_%`.

```
:!echo "%" --> filename or "filename"
```

Like the previous example. Whether you see the double quotes or not depends on your `'shell'`.

```
:echo % --> nothing
```

The '%' is an illegal character in an expression.

```
:echo "%" --> %
```

This just echoes the '%' character.

```
:echo expand("%") --> filename
```

This calls the `expand()` function to expand the '%'

`:echoh` `:echohl`

`:echoh[l] {name}` Use the highlight group `{name}` for the following ``:echo``, ``:echon`` and ``:echormsg`` commands. Also used for the ``input()`` prompt. Example:  
`:echohl WarningMsg | echo "Don't panic!" | echohl None`  
 Don't forget to set the group back to "None", otherwise all following echo's will be highlighted.

`:echom[sg] {expr1} ..` `:echom` `:echormsg`  
 Echo the expression(s) as a true message, saving the message in the `message-history`. Spaces are placed between the arguments as with the ``:echo`` command. But unprintable characters are displayed, not interpreted. The parsing works slightly different from ``:echo``, more like ``:execute``. All the expressions are first evaluated and concatenated before echoing anything. If expressions does not evaluate to a Number or String, `string()` is used to turn it into a string. Uses the highlighting set by the ``:echohl`` command. Example:  
`:echormsg "It's a Zizzer Zazzer Zuzz, as you can plainly see."`  
 See `:echo-redraw` to avoid the message disappearing when the screen is redrawn.

`:[N]echow[indow] {expr1} ..` `:echow` `:echowin` `:echowindow`  
 Like `:echormsg` but when the messages popup window is available the message is displayed there. This means it will show for three seconds and avoid a `hit-enter` prompt. If you want to hide it before that, press Esc in Normal mode (when it would otherwise beep). If it disappears too soon you can use ``:messages`` to see the text. When [*N*] is given then the window will show up for this number of seconds. The last ``:echowindow`` with a count matters, it is used once only. The message window is available when Vim was compiled with the `+timer` and the `+popupwin` features.

`:echoe[rr] {expr1} ..` `:echoe` `:echoerr`  
 Echo the expression(s) as an error message, saving the message in the `message-history`. When used in a script or function the line number will be added. Spaces are placed between the arguments as with the ``:echormsg`` command. When used inside a try conditional, the message is raised as an error exception instead (see `try-echoerr`). Example:  
`:echoerr "This script just failed!"`  
 If you just want a highlighted message use ``:echohl``. And to get a beep:  
`:exe "normal \<Esc>"`

`:echoc[onsole] {expr1} ..` `:echoc` `:echoconsole`

Intended for testing: works like `:echomsg` but when running in the GUI and started from a terminal write the text to stdout.

`:eval {expr}` `:eval`  
Evaluate `{expr}` and discard the result. Example:  
`:eval Getlist()->Filter()->append('$')`

The expression is supposed to have a side effect, since the resulting value is not used. In the example the `append()` call appends the List with text to the buffer. This is similar to `:call` but works with any expression.

In Vim9 script an expression without an effect will result in error `E1207`. This should help noticing mistakes.

The command can be shortened to `:ev` or `:eva`, but these are hard to recognize and therefore not to be used.

The command cannot be followed by `"|"` and another command, since `"|"` is seen as part of the expression.

`:exe[cute] {expr1} ..` `:exe` `:execute`  
Executes the string that results from the evaluation of `{expr1}` as an Ex command.  
Multiple arguments are concatenated, with a space in between. To avoid the extra space use the `".."` operator to concatenate strings into one argument.  
`{expr1}` is used as the processed command, command line editing keys are not recognized.  
Cannot be followed by a comment.

Examples:

```
:execute "buffer" nextbuf
:execute "normal" count .. "w"
```

`":execute"` can be used to append a command to commands that don't accept a `'|'`. Example:

```
:execute '!ls' | echo "theend"
```

`":execute"` is also a nice way to avoid having to type control characters in a Vim script for a `":normal"` command:

```
:execute "normal ixxx\<Esc>"
```

This has an `<Esc>` character, see [expr-string](#).

Be careful to correctly escape special characters in file names. The `fnameescape()` function can be used for Vim commands, `shellescape()` for `:!` commands.

Examples:

```
:execute "e " .. fnameescape(filename)
:execute "!ls " .. shellescape(filename, 1)
```

**Note:** The executed string may be any command-line, but starting or ending "if", "while" and "for" does not always work, because when commands are skipped the ":execute" is not evaluated and Vim loses track of where blocks start and end. Also "break" and "continue" should not be inside ":execute". This example does not work, because the ":execute" is not evaluated and Vim does not see the "while", and gives an error for finding an "endwhile":

```
:if 0
: execute 'while i > 5'
: echo "test"
: endwhile
:endif
```

It is allowed to have a "while" or "if" command completely in the executed string:

```
:execute 'while i < 5 | echo i | let i = i + 1 | endwhile'
```

**:exe-comment**

":execute", ":echo" and ":echon" cannot be followed by a comment directly, because they see the '"' as the start of a string. But, you can use '|' followed by a comment. Example:

```
:echo "foo" | "this is a comment"
```

---

## 8. Exception handling

**exception-handling**

The Vim script language comprises an exception handling feature. This section explains how it can be used in a Vim script.

Exceptions may be raised by Vim on an error or on interrupt, see [catch-errors](#) and [catch-interrupt](#). You can also explicitly throw an exception by using the ":throw" command, see [throw-catch](#).

## TRY CONDITIONALS

**try-conditionals**

Exceptions can be caught or can cause cleanup code to be executed. You can use a try conditional to specify catch clauses (that catch exceptions) and/or a finally clause (to be executed for cleanup).

A try conditional begins with a **:try** command and ends at the matching **:endtry** command. In between, you can use a **:catch** command to start a catch clause, or a **:finally** command to start a finally clause. There may be none or multiple catch clauses, but there is at most one finally clause, which must not be followed by any catch clauses. The lines before the catch clauses and the finally clause is called a try block.

```
:try
: ...
: ...
 TRY BLOCK
```

```

: ...
:catch /{pattern}/
: ...
: ...
: ...
:catch /{pattern}/
: ...
: ...
: ...
:finally
: ...
: ...
: ...
: ...
:endtry

```

CATCH CLAUSE

CATCH CLAUSE

FINALLY CLAUSE

The try conditional allows to watch code for exceptions and to take the appropriate actions. Exceptions from the try block may be caught. Exceptions from the try block and also the catch clauses may cause cleanup actions.

When no exception is thrown during execution of the try block, the control is transferred to the finally clause, if present. After its execution, the script continues with the line following the ":endtry".

When an exception occurs during execution of the try block, the remaining lines in the try block are skipped. The exception is matched against the patterns specified as arguments to the ":catch" commands. The catch clause after the first matching ":catch" is taken, other catch clauses are not executed. The catch clause ends when the next ":catch", ":finally", or ":endtry" command is reached - whatever is first. Then, the finally clause (if present) is executed. When the ":endtry" is reached, the script execution continues in the following line as usual.

When an exception that does not match any of the patterns specified by the ":catch" commands is thrown in the try block, the exception is not caught by that try conditional and none of the catch clauses is executed. Only the finally clause, if present, is taken. The exception pends during execution of the finally clause. It is resumed at the ":endtry", so that commands after the ":endtry" are not executed and the exception might be caught elsewhere, see [try-nesting](#) .

When during execution of a catch clause another exception is thrown, the remaining lines in that catch clause are not executed. The new exception is not matched against the patterns in any of the ":catch" commands of the same try conditional and none of its catch clauses is taken. If there is, however, a finally clause, it is executed, and the exception pends during its execution. The commands following the ":endtry" are not executed. The new exception might, however, be caught elsewhere, see [try-nesting](#) .

When during execution of the finally clause (if present) an exception is thrown, the remaining lines in the finally clause are skipped. If the finally clause has been taken because of an exception from the try block or one of the catch clauses, the original (pending) exception is discarded. The commands following the ":endtry" are not executed, and the exception from the finally clause is propagated and can be caught elsewhere, see [try-nesting](#) .

The finally clause is also executed, when a ":break" or ":continue" for a ":while" loop enclosing the complete try conditional is executed from the try block or a catch clause. Or when a ":return" or ":finish" is executed from the try block or a catch clause of a try conditional in a function or

sourced script, respectively. The `:"break"`, `:"continue"`, `:"return"`, or `:"finish"` pends during execution of the finally clause and is resumed when the `:"endtry"` is reached. It is, however, discarded when an exception is thrown from the finally clause.

When a `:"break"` or `:"continue"` for a `:"while"` loop enclosing the complete try conditional or when a `:"return"` or `:"finish"` is encountered in the finally clause, the rest of the finally clause is skipped, and the `:"break"`, `:"continue"`, `:"return"` or `:"finish"` is executed as usual. If the finally clause has been taken because of an exception or an earlier `:"break"`, `:"continue"`, `:"return"`, or `:"finish"` from the try block or a catch clause, this pending exception or command is discarded.

For examples see [throw-catch](#) and [try-finally](#) .

## NESTING OF TRY CONDITIONALS

[try-nesting](#)

Try conditionals can be nested arbitrarily. That is, a complete try conditional can be put into the try block, a catch clause, or the finally clause of another try conditional. If the inner try conditional does not catch an exception thrown in its try block or throws a new exception from one of its catch clauses or its finally clause, the outer try conditional is checked according to the rules above. If the inner try conditional is in the try block of the outer try conditional, its catch clauses are checked, but otherwise only the finally clause is executed. It does not matter for nesting, whether the inner try conditional is directly contained in the outer one, or whether the outer one sources a script or calls a function containing the inner try conditional.

When none of the active try conditionals catches an exception, just their finally clauses are executed. Thereafter, the script processing terminates. An error message is displayed in case of an uncaught exception explicitly thrown by a `:"throw"` command. For uncaught error and interrupt exceptions implicitly raised by Vim, the error message(s) or interrupt message are shown as usual.

For examples see [throw-catch](#) .

## EXAMINING EXCEPTION HANDLING CODE

[except-examine](#)

Exception handling code can get tricky. If you are in doubt what happens, set `'verbose'` to 13 or use the `:"13verbose"` command modifier when sourcing your script file. Then you see when an exception is thrown, discarded, caught, or finished. When using a verbosity level of at least 14, things pending in a finally clause are also shown. This information is also given in debug mode (see [debug-scripts](#) ).

## THROWING AND CATCHING EXCEPTIONS

[throw-catch](#)

You can throw any number or string as an exception. Use the `:"throw` command and pass the value to be thrown as argument:

```
:"throw 4711
```

```
:throw "string"
```

throw-expression

You can also specify an expression argument. The expression is then evaluated first, and the result is thrown:

```
:throw 4705 + strlen("string")
:throw strpart("strings", 0, 6)
```

An exception might be thrown during evaluation of the argument of the `:throw` command. Unless it is caught there, the expression evaluation is abandoned. The `:throw` command then does not throw a new exception.

Example:

```
:function! Foo(arg)
: try
: throw a:arg
: catch /foo/
: endtry
: return 1
:endfunction
:
:function! Bar()
: echo "in Bar"
: return 4710
:endfunction
:
:throw Foo("arrgh") + Bar()
```

This throws `"arrgh"`, and `"in Bar"` is not displayed since `Bar()` is not executed.

```
:throw Foo("foo") + Bar()
```

however displays `"in Bar"` and throws 4711.

Any other command that takes an expression as argument might also be abandoned by an (uncaught) exception during the expression evaluation. The exception is then propagated to the caller of the command.

Example:

```
:if Foo("arrgh")
: echo "then"
:else
: echo "else"
:endif
```

Here neither of `"then"` or `"else"` is displayed.

catch-order

Exceptions can be caught by a try conditional with one or more `:catch` commands, see [try-conditionals](#). The values to be caught by each `:catch` command can be specified as a pattern argument. The subsequent catch clause gets executed when a matching exception is caught.

Example:

```
:function! Foo(value)
: try
```

```

: throw a:value
: catch /^d\+$/
: echo "Number thrown"
: catch /.*/
: echo "String thrown"
: endtry
:endifunction
:
:call Foo(0x1267)
:call Foo('string')

```

The first call to Foo() displays "Number thrown", the second "String thrown". An exception is matched against the ":catch" commands in the order they are specified. Only the first match counts. So you should place the more specific ":catch" first. The following order does not make sense:

```

: catch /.*/
: echo "String thrown"
: catch /^d\+$/
: echo "Number thrown"

```

The first ":catch" here matches always, so that the second catch clause is never taken.

#### throw-variables

If you catch an exception by a general pattern, you may access the exact value in the variable `v:exception` :

```

: catch /^d\+$/
: echo "Number thrown. Value is" v:exception

```

You may also be interested where an exception was thrown. This is stored in `v:throwpoint` . And you can obtain the stack trace from `v:stacktrace` . **Note** that "v:exception", "v:stacktrace" and "v:throwpoint" are valid for the exception most recently caught as long it is not finished.

Example:

```

:function! Caught()
: if v:exception != ""
: echo 'Caught "' . v:exception .. '" in ' .. v:throwpoint
: else
: echo 'Nothing caught'
: endif
:endifunction
:
:function! Foo()
: try
: try
: try
: throw 4711
: finally
: call Caught()
: endtry
: catch /.*/

```

```

: call Caught()
: throw "oops"
: endtry
: catch /.*/
: call Caught()
: finally
: call Caught()
: endtry
:endfunction
:
:call Foo()

```

This displays

```

Nothing caught
Caught "4711" in function Foo, line 4
Caught "oops" in function Foo, line 10
Nothing caught

```

A practical example: The following command `:LineNumber` displays the line number in the script or function where it has been used:

```

:function! LineNumber()
: return substitute(v:throwpoint, '.*\D(\d\+).*', '\1', "")
:endfunction
:command! LineNumber try | throw "" | catch | echo LineNumber() | endtry

```

[try-nested](#)

An exception that is not caught by a try conditional can be caught by a surrounding try conditional:

```

:try
: try
: throw "foo"
: catch /foobar/
: echo "foobar"
: finally
: echo "inner finally"
: endtry
:catch /foo/
: echo "foo"
:endtry

```

The inner try conditional does not catch the exception, just its finally clause is executed. The exception is then caught by the outer try conditional. The example displays "inner finally" and then "foo".

[throw-from-catch](#)

You can catch an exception and throw a new one to be caught elsewhere from the catch clause:

```

:function! Foo()
: throw "foo"
:endfunction

```

```

:
:function! Bar()
: try
: call Foo()
: catch /foo/
: echo "Caught foo, throw bar"
: throw "bar"
: endtry
:endifunction
:
:try
: call Bar()
:catch /.*/
: echo "Caught" v:exception
:endifunction

```

This displays "Caught foo, throw bar" and then "Caught bar".

**rethrow**

There is no real rethrow in the Vim script language, but you may throw "v:exception" instead:

```

:function! Bar()
: try
: call Foo()
: catch /.*/
: echo "Rethrow" v:exception
: throw v:exception
: endtry
:endifunction

```

**try-echoerr**

**Note** that this method cannot be used to "rethrow" Vim error or interrupt exceptions, because it is not possible to fake Vim internal exceptions. Trying so causes an error exception. You should throw your own exception denoting the situation. If you want to cause a Vim error exception containing the original error exception value, you can use the `:echoerr` command:

```

:try
: try
: asdf
: catch /.*/
: echoerr v:exception
: endtry
:catch /.*/
: echo v:exception
:endifunction

```

This code displays

```
Vim(echoerr):Vim:E492: Not an editor command: asdf
```

**CLEANUP CODE**

**try-finally**

Scripts often change global settings and restore them at their end. If the user however interrupts the script by pressing **CTRL-C**, the settings remain in an inconsistent state. The same may happen to you in the development phase of a script when an error occurs or you explicitly throw an exception without catching it. You can solve these problems by using a try conditional with a finally clause for restoring the settings. Its execution is guaranteed on normal control flow, on error, on an explicit `:throw`, and on interrupt. (Note that errors and interrupts from inside the try conditional are converted to exceptions. When not caught, they terminate the script after the finally clause has been executed.)

Example:

```
:try
: let s:saved_ts = &ts
: set ts=17
:
: " Do the hard work here.
:
:finally
: let &ts = s:saved_ts
: unset s:saved_ts
:endtry
```

This method should be used locally whenever a function or part of a script changes global settings which need to be restored on failure or normal exit of that function or script part.

#### break-finally

Cleanup code works also when the try block or a catch clause is left by a `:continue`, `:break`, `:return`, or `:finish`.

Example:

```
:let first = 1
:while 1
: try
: if first
: echo "first"
: let first = 0
: continue
: else
: throw "second"
: endif
: catch ././
: echo v:exception
: break
: finally
: echo "cleanup"
: endtry
: echo "still in while"
:endwhile
:echo "end"
```

This displays "first", "cleanup", "second", "cleanup", and "end".

```

: function! Foo()
: try
: return 4711
: finally
: echo "cleanup\n"
: endtry
: echo "Foo still active"
: endfunction
:
: echo Foo() "returned by Foo"

```

This displays "cleanup" and "4711 returned by Foo". You don't need to add an extra ":return" in the finally clause. (Above all, this would override the return value.)

### except-from-finally

Using either of ":continue", ":break", ":return", ":finish", or ":throw" in a finally clause is possible, but not recommended since it abandons the cleanup actions for the try conditional. But, of course, interrupt and error exceptions might get raised from a finally clause.

Example where an error in the finally clause stops an interrupt from working correctly:

```

: try
: try
: echo "Press CTRL-C for interrupt"
: while 1
: endwhile
: finally
: unlet novar
: endtry
: catch /novar/
: endtry
: echo "Script still running"
: sleep 1

```

If you need to put commands that could fail into a finally clause, you should think about catching or ignoring the errors in these commands, see [catch-errors](#) and [ignore-errors](#) .

## CATCHING ERRORS

### catch-errors

If you want to catch specific errors, you just have to put the code to be watched in a try block and add a catch clause for the error message. The presence of the try conditional causes all errors to be converted to an exception. No message is displayed and `v:errmsg` is not set then. To find the right pattern for the ":catch" command, you have to know how the format of the error exception is.

Error exceptions have the following format:

```
Vim({cmdname}):{errmsg}
```

or

```
Vim:{errmsg}
```

`{cmdname}` is the name of the command that failed; the second form is used when the command name is not known. `{errmsg}` is the error message usually produced when the error occurs outside try conditionals. It always begins with a capital "E", followed by a two or three-digit error number, a colon, and a space.

Examples:

The command

```
:unlet novar
```

normally produces the error message

```
E108: No such variable: "novar"
```

which is converted inside try conditionals to an exception

```
Vim(unlet):E108: No such variable: "novar"
```

The command

```
:dwim
```

normally produces the error message

```
E492: Not an editor command: dwim
```

which is converted inside try conditionals to an exception

```
Vim:E492: Not an editor command: dwim
```

You can catch all ":unlet" errors by a

```
:catch /^Vim(unlet):/
```

or all errors for misspelled command names by a

```
:catch /^Vim:E492:/
```

Some error messages may be produced by different commands:

```
:function nofunc
```

and

```
:delfunction nofunc
```

both produce the error message

```
E128: Function name must start with a capital: nofunc
```

which is converted inside try conditionals to an exception

```
Vim(function):E128: Function name must start with a capital: nofunc
```

or

```
Vim(delfunction):E128: Function name must start with a capital: nofunc
```

respectively. You can catch the error by its number independently on the command that caused it if you use the following pattern:

```
:catch /^Vim(\a\+):E128:/
```

Some commands like

```
:let x = novar
```

produce multiple error messages, here:

```
E121: Undefined variable: novar
```

```
E15: Invalid expression: novar
```

Only the first is used for the exception value, since it is the most specific one (see [except-several-errors](#)). So you can catch it by

```
:catch /^Vim(\a\+):E121:/
```

You can catch all errors related to the name "nofunc" by

```
:catch /\<nofunc\>/
```

You can catch all Vim errors in the ":write" and ":read" commands by

```
:catch /^Vim(\(write\|read\)):E\d\+:/
```

You can catch all Vim errors by the pattern

```
:catch /^Vim\((\a\+)\)\|=E\d\+:/
```

catch-text

**NOTE:** You should never catch the error message text itself:

```
:catch /No such variable/
```

only works in the English locale, but not when the user has selected a different language by the `:language` command. It is however helpful to cite the message text in a comment:

```
:catch /^Vim(\a\+):E108:/ " No such variable
```

## IGNORING ERRORS

ignore-errors

You can ignore errors in a specific Vim command by catching them locally:

```
:try
: write
:catch
:endtry
```

But you are strongly recommended NOT to use this simple form, since it could catch more than you want. With the ":write" command, some autocommands could be executed and cause errors not related to writing, for instance:

```
:au BufWritePre * unlet novar
```

There could even be such errors you are not responsible for as a script writer: a user of your script might have defined such autocommands. You would then hide the error from the user.

It is much better to use

```
:try
: write
:catch /^Vim(write):/
:endtry
```

which only catches real write errors. So catch only what you'd like to ignore intentionally.

For a single command that does not cause execution of autocommands, you could even suppress the conversion of errors to exceptions by the ":silent!" command:

```
:silent! nunmap k
```

This works also when a try conditional is active.

## CATCHING INTERRUPTS

catch-interrupt

When there are active try conditionals, an interrupt (CTRL-C) is converted to the exception "Vim:Interrupt". You can catch it like every exception. The

script is not terminated, then.

Example:

```
:function! TASK1()
: sleep 10
:endfunction

:function! TASK2()
: sleep 20
:endfunction

:while 1
: let command = input("Type a command: ")
: try
: if command == ""
: continue
: elseif command == "END"
: break
: elseif command == "TASK1"
: call TASK1()
: elseif command == "TASK2"
: call TASK2()
: else
: echo "\nIllegal command:" command
: continue
: endif
: catch /^Vim:Interrupt$/
: echo "\nCommand interrupted"
: " Caught the interrupt. Continue with next prompt.
: endtry
:endwhile
```

You can interrupt a task here by pressing **CTRL-C**; the script then asks for a new command. If you press **CTRL-C** at the prompt, the script is terminated.

For testing what happens when **CTRL-C** would be pressed on a specific line in your script, use the debug mode and execute the `>quit` or `>interrupt` command on that line. See [debug-scripts](#) .

## CATCHING ALL

`catch-all`

The commands

```
:catch /.*/
:catch //
:catch
```

catch everything, error exceptions, interrupt exceptions and exceptions explicitly thrown by the `:throw` command. This is useful at the top level of a script in order to catch unexpected things.

Example:

```
:try
```

```

:
: " do the hard work here
:
:catch /MyException/
:
: " handle known problem
:
:catch /^Vim:Interrupt$/
: echo "Script interrupted"
:catch /.*/
: echo "Internal error (" .. v:exception .. ")"
: echo " - occurred at " .. v:throwpoint
:endtry
:" end of script

```

**Note:** Catching all might catch more things than you want. Thus, you are strongly encouraged to catch only for problems that you can really handle by specifying a pattern argument to the ":catch".

Example: Catching all could make it nearly impossible to interrupt a script by pressing **CTRL-C**:

```

:while 1
: try
: sleep 1
: catch
: endtry
:endwhile

```

## EXCEPTIONS AND AUTOCOMMANDS

except-autocmd

Exceptions may be used during execution of autocommands. Example:

```

:autocmd User x try
:autocmd User x throw "Oops!"
:autocmd User x catch
:autocmd User x echo v:exception
:autocmd User x endtry
:autocmd User x throw "Arrgh!"
:autocmd User x echo "Should not be displayed"
:
:try
: doautocmd User x
:catch
: echo v:exception
:endtry

```

This displays "Oops!" and "Arrgh!".

except-autocmd-Pre

For some commands, autocommands get executed before the main action of the command takes place. If an exception is thrown and not caught in the sequence of autocommands, the sequence and the command that caused its execution are abandoned and the exception is propagated to the caller of the command.

Example:

```
:autocmd BufWritePre * throw "FAIL"
:autocmd BufWritePre * echo "Should not be displayed"
:
:try
: write
:catch
: echo "Caught:" v:exception "from" v:throwpoint
:endtry
```

Here, the ":write" command does not write the file currently being edited (as you can see by checking '**modified**'), since the exception from the BufWritePre autocommand abandons the ":write". The exception is then caught and the script displays:

```
Caught: FAIL from BufWrite Auto commands for "*"
```

[except-autocmd-Post](#)

For some commands, autocommands get executed after the main action of the command has taken place. If this main action fails and the command is inside an active try conditional, the autocommands are skipped and an error exception is thrown that can be caught by the caller of the command.

Example:

```
:autocmd BufWritePost * echo "File successfully written!"
:
:try
: write /i/m/p/o/s/s/i/b/l/e
:catch
: echo v:exception
:endtry
```

This just displays:

```
Vim(write):E212: Can't open file for writing (/i/m/p/o/s/s/i/b/l/e)
```

If you really need to execute the autocommands even when the main action fails, trigger the event from the catch clause.

Example:

```
:autocmd BufWritePre * set noreadonly
:autocmd BufWritePost * set readonly
:
:try
: write /i/m/p/o/s/s/i/b/l/e
:catch
: doautocmd BufWritePost /i/m/p/o/s/s/i/b/l/e
:endtry
```

You can also use ":silent!":

```
:let x = "ok"
:let v:errmsg = ""
```

```

:autocmd BufWritePost * if v:errmsg != ""
:autocmd BufWritePost * let x = "after fail"
:autocmd BufWritePost * endif
:try
: silent! write /i/m/p/o/s/s/i/b/l/e
:catch
:entry
:echo x

```

This displays "after fail".

If the main action of the command does not fail, exceptions from the autocommands will be catchable by the caller of the command:

```

:autocmd BufWritePost * throw ":-("
:autocmd BufWritePost * echo "Should not be displayed"
:
:try
: write
:catch
: echo v:exception
:entry

```

#### except-autocmd-Cmd

For some commands, the normal action can be replaced by a sequence of autocommands. Exceptions from that sequence will be catchable by the caller of the command.

Example: For the ":write" command, the caller cannot know whether the file had actually been written when the exception occurred. You need to tell it in some way.

```

:if !exists("cnt")
: let cnt = 0
:
:
: autocmd BufWriteCmd * if &modified
: autocmd BufWriteCmd * let cnt = cnt + 1
: autocmd BufWriteCmd * if cnt % 3 == 2
: autocmd BufWriteCmd * throw "BufWriteCmdError"
: autocmd BufWriteCmd * endif
: autocmd BufWriteCmd * write | set nomodified
: autocmd BufWriteCmd * if cnt % 3 == 0
: autocmd BufWriteCmd * throw "BufWriteCmdError"
: autocmd BufWriteCmd * endif
: autocmd BufWriteCmd * echo "File successfully written!"
: autocmd BufWriteCmd * endif
:endif
:
:try
: write
:catch /^BufWriteCmdError$/
: if &modified
: echo "Error on writing (file contents not changed)"
: else
: echo "Error after writing"

```

```

: endif
:catch /^Vim(write):/
: echo "Error on writing"
:entry

```

When this script is sourced several times after making changes, it displays first

```

File successfully written!
then
Error on writing (file contents not changed)
then
Error after writing
etc.

```

[except-autocmd-ill](#)

You cannot spread a try conditional over autocommands for different events. The following code is ill-formed:

```

:autocmd BufWritePre * try
:
:autocmd BufWritePost * catch
:autocmd BufWritePost * echo v:exception
:autocmd BufWritePost * endtry
:
:write

```

## EXCEPTION HIERARCHIES AND PARAMETERIZED EXCEPTIONS

[except-hier-param](#)

Some programming languages allow to use hierarchies of exception classes or to pass additional information with the object of an exception class. You can do similar things in Vim.

In order to throw an exception from a hierarchy, just throw the complete class name with the components separated by a colon, for instance throw the string "EXCEPT:MATHERR:OVERFLOW" for an overflow in a mathematical library.

When you want to pass additional information with your exception class, add it in parentheses, for instance throw the string "EXCEPT:IO:WRITEERR(myfile)" for an error when writing "myfile".

With the appropriate patterns in the ":catch" command, you can catch for base classes or derived classes of your hierarchy. Additional information in parentheses can be cut out from `v:exception` with the ":substitute" command.

Example:

```

:function! CheckRange(a, func)
: if a:a < 0
: throw "EXCEPT:MATHERR:RANGE(" .. a:func .. ")"
: endif
:endif
:endifunction
:
:function! Add(a, b)
: call CheckRange(a:a, "Add")
: call CheckRange(a:b, "Add")
: let c = a:a + a:b
: if c < 0

```

```

: throw "EXCEPT:MATHERR:OVERFLOW"
: endif
: return c
:endifunction
:
:
:function! Div(a, b)
: call CheckRange(a:a, "Div")
: call CheckRange(a:b, "Div")
: if (a:b == 0)
: throw "EXCEPT:MATHERR:ZERODIV"
: endif
: return a:a / a:b
:endifunction
:
:
:function! Write(file)
: try
: execute "write" fnameescape(a:file)
: catch /^Vim(write):/
: throw "EXCEPT:IO(" .. getcwd() .. ", " .. a:file .. "):WRITEERR"
: endtry
:endifunction
:
:
:try
:
: " something with arithmetic and I/O
:
:catch /^EXCEPT:MATHERR:RANGE/
: let function = substitute(v:exception, '.*(\(\a+\)).*', '\1', "")
: echo "Range error in" function
:
:catch /^EXCEPT:MATHERR/ " catches OVERFLOW and ZERODIV
: echo "Math error"
:
:catch /^EXCEPT:IO/
: let dir = substitute(v:exception, '.*(\(.+\),\s*\.+).*', '\1', "")
: let file = substitute(v:exception, '.*(\.+,\s*\(.+\)).*', '\1', "")
: if file !~ '^/'
: let file = dir .. "/" .. file
: endif
: echo 'I/O error for "' .. file .. "'"
:
:catch /^EXCEPT/
: echo "Unspecified error"
:
:
:entry

```

The exceptions raised by Vim itself (on error or when pressing **CTRL-C**) use a flat hierarchy: they are all in the "Vim" class. You cannot throw yourself exceptions with the "Vim" prefix; they are reserved for Vim.

Vim error exceptions are parameterized with the name of the command that failed, if known. See [catch-errors](#) .

## PECULIARITIES

## except-compact

The exception handling concept requires that the command sequence causing the exception is aborted immediately and control is transferred to finally clauses and/or a catch clause.

In the Vim script language there are cases where scripts and functions continue after an error: in functions without the "abort" flag or in a command after ":silent!", control flow goes to the following line, and outside functions, control flow goes to the line following the outermost ":endwhile" or ":endif". On the other hand, errors should be catchable as exceptions (thus, requiring the immediate abortion).

This problem has been solved by converting errors to exceptions and using immediate abortion (if not suppressed by ":silent!") only when a try conditional is active. This is no restriction since an (error) exception can be caught only from an active try conditional. If you want an immediate termination without catching the error, just use a try conditional without catch clause. (You can cause cleanup code being executed before termination by specifying a finally clause.)

When no try conditional is active, the usual abortion and continuation behavior is used instead of immediate abortion. This ensures compatibility of scripts written for Vim 6.1 and earlier.

However, when sourcing an existing script that does not use exception handling commands (or when calling one of its functions) from inside an active try conditional of a new script, you might change the control flow of the existing script on error. You get the immediate abortion on error and can catch the error in the new script. If however the sourced script suppresses error messages by using the ":silent!" command (checking for errors by testing `v:errmsg` if appropriate), its execution path is not changed. The error is not converted to an exception. (See `:silent`.) So the only remaining cause where this happens is for scripts that don't care about errors and produce error messages. You probably won't want to use such code from your new scripts.

## except-syntax-err

Syntax errors in the exception handling commands are never caught by any of the ":catch" commands of the try conditional they belong to. Its finally clauses, however, is executed.

Example:

```
:try
: try
: throw 4711
: catch /\(/
: echo "in catch with syntax error"
: catch
: echo "inner catch-all"
: finally
: echo "inner finally"
: endtry
:catch
: echo 'outer catch-all caught "' .. v:exception .. "'
```

```

: finally
: echo "outer finally"
:entry

```

This displays:

```

inner finally
outer catch-all caught "Vim(catch):E54: Unmatched \("
outer finally

```

The original exception is discarded and an error exception is raised, instead.

#### except-single-line

The `":try"`, `":catch"`, `":finally"`, and `":entry"` commands can be put on a single line, but then syntax errors may make it difficult to recognize the `"catch"` line, thus you better avoid this.

Example:

```

:try | unlet! foo # | catch | endtry

```

raises an error exception for the trailing characters after the `":unlet!"` argument, but does not see the `":catch"` and `":entry"` commands, so that the error exception is discarded and the `"E488: Trailing characters"` message gets displayed.

#### except-several-errors

When several errors appear in a single command, the first error message is usually the most specific one and therefore converted to the error exception.

Example:

```

echo novar

```

causes

```

E121: Undefined variable: novar
E15: Invalid expression: novar

```

The value of the error exception inside try conditionals is:

```

Vim(echo):E121: Undefined variable: novar

```

#### except-syntax-error

But when a syntax error is detected after a normal error in the same command, the syntax error is used for the exception being thrown.

Example:

```

unlet novar #

```

causes

```

E108: No such variable: "novar"
E488: Trailing characters

```

The value of the error exception inside try conditionals is:

```

Vim(unlet):E488: Trailing characters

```

This is done because the syntax error might change the execution path in a way not intended by the user. Example:

```

try
 try | unlet novar # | catch | echo v:exception | endtry
catch /.*/
 echo "outer catch:" v:exception
endtry

```

This displays `"outer catch: Vim(unlet):E488: Trailing characters"`, and then a `"E600: Missing :endtry"` error message is given, see [except-single-line](#) .

=====

## 9. Examples

#### eval-examples

## Printing in Binary

```
:" The function Nr2Bin() returns the binary string representation of a number.
:func Nr2Bin(nr)
: let n = a:nr
: let r = ""
: while n
: let r = '01'[n % 2] .. r
: let n = n / 2
: endwhile
: return r
:endfunc

:" The function String2Bin() converts each character in a string to a
:" binary string, separated with dashes.
:func String2Bin(str)
: let out = ''
: for ix in range(strlen(a:str))
: let out = out .. '-' .. Nr2Bin(char2nr(a:str[ix]))
: endfor
: return out[1:]
:endfunc
```

Example of its use:

```
:echo Nr2Bin(32)
result: "100000"
:echo String2Bin("32")
result: "110011-110010"
```

## Sorting lines

This example sorts lines with a specific compare function.

```
:func SortBuffer()
: let lines = getline(1, '$')
: call sort(lines, function("Strcmp"))
: call setline(1, lines)
:endfunction
```

As a one-liner:

```
:call setline(1, sort(getline(1, '$'), function("Strcmp")))
```

## scanf() replacement

### sscanf

There is no sscanf() function in Vim. If you need to extract parts from a line, you can use matchstr() and substitute() to do it. This example shows how to get the file name, line number and column number out of a line like "foobar.txt, 123, 45".

```
:" Set up the match bit
:let mx='\(\\f\\+\\),\\s*\\(\\d\\+\\),\\s*\\(\\d\\+\\)'
:"get the part matching the whole expression
:let l = matchstr(line, mx)
```

```

:"get each item out of the match
:let file = substitute(l, mx, '\1', '')
:let lnum = substitute(l, mx, '\2', '')
:let col = substitute(l, mx, '\3', '')

```

The input is in the variable "line", the results in the variables "file", "lnum" and "col". (idea from Michael Geddes)

### getting the scriptnames in a Dictionary

#### scriptnames-dictionary

The `:scriptnames` command can be used to get a list of all script files that have been sourced. There is also the `getscriptinfo()` function, but the information returned is not exactly the same. In case you need to manipulate the list, this code can be used as a base:

```

Create or update scripts dictionary, indexed by SNR, and return it.
def Scripts(scripts: dict<string> = {}): dict<string>
 for info in getscriptinfo()
 if scripts->has_key(info.sid)
 continue
 endif
 scripts[info.sid] = info.name
 endfor
 return scripts
enddef

```

### 10. Vim script versions

#### vimscript-version vimscript-versions scriptversion

Over time many features have been added to Vim script. This includes Ex commands, functions, variable types, etc. Each individual feature can be checked with the `has()` and `exists()` functions.

Sometimes old syntax of functionality gets in the way of making Vim better. When support is taken away this will break older Vim scripts. To make this explicit the `:scriptversion` command can be used. When a Vim script is not compatible with older versions of Vim this will give an explicit error, instead of failing in mysterious ways.

When using a legacy function, defined with `:function`, in Vim9 script then `scriptversion 4` is used.

#### scriptversion-1

##### :scriptversion 1

This is the original Vim script, same as not using a `:scriptversion` command. Can be used to go back to old syntax for a range of lines.

Test for support with:

```
has('vimscript-1')
```

#### scriptversion-2

##### :scriptversion 2

String concatenation with "." is not supported, use ".." instead.

This avoids the ambiguity using "." for Dict member access and

floating point numbers. Now ".5" means the number 0.5.

### scriptversion-3

#### :scriptversion 3

All `vim-variable`s must be prefixed by "v:". E.g. "version" doesn't work as `v:version` anymore, it can be used as a normal variable. Same for some obvious names as "count" and others.

Test for support with:  
`has('vimscrip-3')`

### scriptversion-4

#### :scriptversion 4

Numbers with a leading zero are not recognized as octal. "0o" or "0O" is still recognized as octal. With the previous version you get:

```
echo 017 " displays 15 (octal)
echo 0o17 " displays 15 (octal)
echo 018 " displays 18 (decimal)
```

with script version 4:

```
echo 017 " displays 17 (decimal)
echo 0o17 " displays 15 (octal)
echo 018 " displays 18 (decimal)
```

Also, it is possible to use single quotes inside numbers to make them easier to read:

```
echo 1'000'000
```

The quotes must be surrounded by digits.

Test for support with:  
`has('vimscrip-4')`

---

## 11. No +eval feature

### no-eval-feature

When the `+eval` feature was disabled at compile time, none of the expression evaluation commands are available. To prevent this from causing Vim scripts to generate all kinds of errors, the `:"if` and `:"endif` commands are still recognized, though the argument of the `:"if` and everything between the `:"if` and the matching `:"endif` is ignored. Nesting of `:"if` blocks is allowed, but only if the commands are at the start of the line. The `:"else` command is not recognized.

Example of how to avoid executing commands when the `+eval` feature is missing:

```
:"if 1
: echo "Expression evaluation is compiled in"
:"else
: echo "You will _never_ see this message"
:"endif
```

To execute a command only when the `+eval` feature is disabled can be done in two ways. The simplest is to exit the script (or Vim) prematurely:

```
if 1
```

```

 echo "commands executed with +eval"
 finish
endif
args " command executed without +eval

```

If you do not want to abort loading the script you can use a trick, as this example shows:

```

silent! while 0
 set history=111
silent! endwhile

```

When the `+eval` feature is available the command is skipped because of the "while 0". Without the `+eval` feature the "while 0" is an error, which is silently ignored, and the command is executed.

---

## 12. The sandbox

`eval-sandbox` `sandbox`

The `'foldexpr'`, `'formatexpr'`, `'includeexpr'`, `'indentexpr'`, `'statusline'` and `'foldtext'` options may be evaluated in a sandbox. This means that you are protected from these expressions having nasty side effects. This gives some safety for when these options are set from a modeline. It is also used when the command from a tags file is executed and for **CTRL-R** = in the command line. The sandbox is also used for the `:sandbox` command.

E48

These items are not allowed in the sandbox:

- changing the buffer text
- defining or changing mapping, autocommands, user commands
- setting certain options (see `option-summary` )
- setting certain v: variables (see `v:var` ) E794
- executing a shell command
- reading or writing a file
- jumping to another buffer or editing a file
- executing Python, Perl, etc. commands

This is not guaranteed 100% secure, but it should block most attacks.

`:san[dbox] {cmd}`      Execute `{cmd}` in the sandbox. Useful to evaluate an option that may have been set from a modeline, e.g. `'foldexpr'`.

`:san`    `:sandbox`

`sandbox-option`

A few options contain an expression. When this expression is evaluated it may have to be done in the sandbox to avoid a security risk. But the sandbox is restrictive, thus this only happens when the option was set from an insecure location. Insecure in this context are:

- sourcing a `.vimrc` or `.exrc` in the current directory
- while executing in the sandbox
- value coming from a modeline
- executing a function that was defined in the sandbox

**Note** that when in the sandbox and saving an option value and restoring it, the option will still be marked as it was set in the sandbox.

---

### 13. Textlock

textlock

In a few situations it is not allowed to change the text in the buffer, jump to another window and some other things that might confuse or break what Vim is currently doing. This mostly applies to things that happen when Vim is actually doing something else. For example, evaluating the `'balloonexpr'` may happen any moment the mouse cursor is resting at some position.

This is not allowed when the textlock is active:

- changing the buffer text
- jumping to another buffer or window
- editing another file
- closing a window or quitting Vim
- etc.

---

### 14. Vim script library

vim-script-library

Vim comes bundled with a Vim script library, that can be used by runtime, script authors. Currently, it only includes very few functions, but it may grow over time.

The functions are available as `Vim9-script` as well as using legacy Vim script (to be used for non Vim 9.0 versions and Neovim).

dist#vim dist#vim9

The functions make use of the autoloader prefix "dist#vim" (for legacy Vim script and Neovim) and "dist#vim9" for Vim9 script.

The following functions are available:

```
dist#vim#IsSafeExecutable(filetype, executable)
dist#vim9#IsSafeExecutable(filetype:string, executable:string): bool
```

This function takes a filetype and an executable and checks whether it is safe to execute the given executable. For security reasons users may not want to have Vim execute random executables or may have forbidden to do so for specific filetypes by setting the "`<filetype>_exec`" variable ( `plugin_exec` ).

It returns `true` or `false` to indicate whether the plugin should run the given executable. It takes the following arguments:

argument	type
filetype	string
executable	string

dist#vim9#Open() :Open  
g:Openprg gx

```
dist#vim9#Open(file: string)
```

Opens ``path`` with the system default handler (macOS ``open``, Windows

`explorer.exe`, Linux `xdg-open`, ...). If the variable `g:Openprg` exists the string specified in the variable is used instead.

This function is by default called using the `gx` mapping. In visual mode tries to open the visually selected text.

Associated setting variables:

`g:gx_word`: control how `gx` picks up the text under the cursor. Uses `g:netrw_gx` as a fallback for backward compatibility. (default: ``<cfile>``)

`g:nogx`: disables the `gx` mapping. Uses `g:netrw_nogx` as a fallback for backward compatibility. (default: `unset`)

**NOTE:** Escaping of the path is automatically applied.

Usage: `>vim`  
    `:call dist#vim9#Open(<path>)`  
    `:Open <path>`

<

`dist#vim9#Launch()`   `:Launch`

`dist#vim9#Launch(file: string)`

Launches `<args>` with the appropriate system programs. Intended for launching GUI programs within Vim.

**NOTE:** escaping of `<args>` is left to the user

Examples: `>vim`  
    `vim9script`  
  
    `import autoload 'dist/vim9.vim'`  
    `# Execute 'makeprg' into another xterm window`  
    `vim9.Launch('xterm ' .. expandcmd(&makeprg))`

<

Usage: `>vim`  
    `:call dist#vim9#Launch(<args>)`  
    `:Launch <app> <args>.`

<

Builtin functions

builtin-functions

Note: Expression evaluation can be disabled at compile time, the builtin functions are not available then. See +eval and no-eval-feature .

USAGE

RESULT DESCRIPTION

abs({expr})	Float or Number	absolute value of {expr}
acos({expr})	Float	arc cosine of {expr}
add({object}, {item})	List/Blob	append {item} to {object}
and({expr}, {expr})	Number	bitwise AND
append({lnum}, {text})	Number	append {text} below line {lnum}
appendbufline({buf}, {lnum}, {text})	Number	append {text} below line {lnum} in buffer {buf}
argc([winid])	Number	number of files in the argument list
argidx()	Number	current index in the argument list
arglistid([winnr] [, tabnr])	Number	argument list id
argv({nr} [, winid])	String	{nr} entry of the argument list
argv([-1, winid])	List	the argument list
asin({expr})	Float	arc sine of {expr}
assert_beeps({cmd})	Number	assert {cmd} causes a beep
assert_equal({exp}, {act} [, msg])	Number	assert {exp} is equal to {act}
assert_equalfile({fname-one}, {fname-two} [, msg])	Number	assert file contents are equal
assert_exception({error} [, msg])	Number	assert {error} is in v:exception
assert_fails({cmd} [, error] [, msg] [, lnum] [, context])	Number	assert {cmd} fails
assert_false({actual} [, msg])	Number	assert {actual} is false
assert_inrange({lower}, {upper}, {actual} [, msg])	Number	assert {actual} is inside the range
assert_match({pat}, {text} [, msg])	Number	assert {pat} matches {text}

assert_nobeep({cmd})	Number	assert {cmd} does not cause a beep
assert_notequal({exp}, {act} [, {msg}])	Number	assert {exp} is not equal {act}
assert_notmatch({pat}, {text} [, {msg}])	Number	assert {pat} not matches {text}
assert_report({msg})	Number	report a test failure
assert_true({actual} [, {msg}])	Number	assert {actual} is true
atan({expr})	Float	arc tangent of {expr}
atan2({expr1}, {expr2})	Float	arc tangent of {expr1} / {expr2}
autocmd_add({acmds})	Bool	add a list of autocmds and groups
autocmd_delete({acmds})	Bool	delete a list of autocmds and groups
autocmd_get([opts])	List	return a list of autocmds
balloon_gettext()	String	current text in the balloon
balloon_show({expr})	none	show {expr} inside the balloon
balloon_split({msg})	List	split {msg} as used for a balloon
base64_decode({string})	Blob	base64 decode {string} characters
base64_encode({blob})	String	base64 encode the bytes in {blob}
bindtextdomain({package}, {path})	Bool	bind text domain to specified path
blob2list({blob})	List	convert {blob} into a list of numbers
blob2str({blob} [, {options}])	List	convert {blob} into a list of strings
browse({save}, {title}, {initdir}, {default})	String	put up a file requester
browsedir({title}, {initdir})	String	put up a directory requester
bufadd({name})	Number	add a buffer to the buffer list
bufexists({buf})	Number	TRUE if buffer {buf} exists
buflisted({buf})	Number	TRUE if buffer {buf} is listed
bufload({buf})	Number	load buffer {buf} if not loaded yet
bufloaded({buf})	Number	TRUE if buffer {buf} is loaded
bufname([{buf}])	String	Name of the buffer {buf}
bufnr([{buf} [, {create}])	Number	Number of the buffer {buf}
bufwinid({buf})	Number	window ID of buffer {buf}
bufwinnr({buf})	Number	window number of buffer {buf}
byte2line({byte})	Number	line number at byte count {byte}
byteidx({expr}, {nr} [, {utf16}])	Number	byte index of {nr}'th char in {expr}
byteidxcomp({expr}, {nr} [, {utf16}])	Number	byte index of {nr}'th char in {expr}
call({func}, {arglist} [, {dict}])	any	call {func} with arguments {arglist}
ceil({expr})	Float	round {expr} up
ch_canread({handle})	Number	check if there is something to read
ch_close({handle})	none	close {handle}
ch_close_in({handle})	none	close in part of {handle}
ch_evalexpr({handle}, {expr} [, {options}])	any	evaluate {expr} on JSON {handle}
ch_evalraw({handle}, {string} [, {options}])	any	evaluate {string} on raw {handle}
ch_getbufnr({handle}, {what})	Number	get buffer number for {handle}/{what}
ch_getjob({channel})	Job	get the Job of {channel}
ch_info({handle})	String	info about channel {handle}
ch_log({msg} [, {handle}])	none	write {msg} in the channel log file
ch_logfile({fname} [, {mode}])	none	start logging channel activity
ch_open({address} [, {options}])		

	Channel	open a channel to {address}
ch_read({handle} [, {options}])	String	read from {handle}
ch_readblob({handle} [, {options}])	Blob	read Blob from {handle}
ch_readraw({handle} [, {options}])	String	read raw from {handle}
ch_sendexpr({handle}, {expr} [, {options}])	any	send {expr} over JSON {handle}
ch_sendraw({handle}, {expr} [, {options}])	any	send {expr} over raw {handle}
ch_setoptoptions({handle}, {options})	none	set options for {handle}
ch_status({handle} [, {options}])	String	status of channel {handle}
changenr()	Number	current change number
char2nr({expr} [, {utf8}])	Number	ASCII/UTF-8 value of first char in {expr}
charclass({string})	Number	character class of {string}
charcol({expr} [, {winid}])	Number	column number of cursor or mark
charidx({string}, {idx} [, {countcc} [, {utf16}]])	Number	char index of byte {idx} in {string}
chdir({dir})	String	change current working directory
cindent({lnum})	Number	C indent for line {lnum}
clearmatches([win])	none	clear all matches
col({expr} [, {winid}])	Number	column byte index of cursor or mark
complete({startcol}, {matches})	none	set Insert mode completion
complete_add({expr})	Number	add completion match
complete_check()	Number	check for key typed during completion
complete_info([what])	Dict	get current completion information
confirm({msg} [, {choices} [, {default} [, {type}]]])	Number	number of choice picked by user
copy({expr})	any	make a shallow copy of {expr}
cos({expr})	Float	cosine of {expr}
cosh({expr})	Float	hyperbolic cosine of {expr}
count({comp}, {expr} [, {ic} [, {start}]])	Number	count how many {expr} are in {comp}
cscope_connection([num], {dbpath} [, {prepend}])	Number	checks existence of cscope connection
cursor({lnum}, {col} [, {off}])	Number	move cursor to {lnum}, {col}, {off}
cursor({list})	Number	move cursor to position in {list}
debugbreak({pid})	Number	interrupt process being debugged
deepcopy({expr} [, {noref}])	any	make a full copy of {expr}
delete({fname} [, {flags}])	Number	delete the file or directory {fname}
deletebuflines({buf}, {first} [, {last}])	Number	delete lines from buffer {buf}
did_filetype()	Number	TRUE if FileType autocmd event used
diff({fromlist}, {tolist} [, {options}])	List	diff two Lists of strings
diff_filler({lnum})	Number	diff filler lines about {lnum}
diff_hlID({lnum}, {col})	Number	diff highlighting at {lnum}/{col}
digraph_get({chars})	String	get the digraph of {chars}
digraph_getlist([listall])	List	get all digraphs
digraph_set({chars}, {digraph})	Bool	register digraph
digraph_setlist({digraphlist})	Bool	register multiple digraphs

echoraw({expr})	none	output {expr} as-is
empty({expr})	Number	TRUE if {expr} is empty
environ()	Dict	return environment variables
err_teapot([ {expr} ])	none	give E418, or E503 if {expr} is TRUE
escape({string}, {chars})	String	escape {chars} in {string} with '\'
eval({string})	any	evaluate {string} into its value
eventhandler()	Number	TRUE if inside an event handler
executable({expr})	Number	1 if executable {expr} exists
execute({command})	String	execute {command} and get the output
exepath({expr})	String	full path of the command {expr}
exists({expr})	Number	TRUE if {expr} exists
exists_compiled({expr})	Number	TRUE if {expr} exists at compile time
exp({expr})	Float	exponential of {expr}
expand({expr} [, {nosuf} [, {list} ]])	any	expand special keywords in {expr}
expandcmd({string} [, {options} ])	String	expand {string} like with `:edit`
extend({expr1}, {expr2} [, {expr3} ])	List/Dict	insert items of {expr2} into {expr1}
extendnew({expr1}, {expr2} [, {expr3} ])	List/Dict	like extend() but creates a new List or Dictionary
feedkeys({string} [, {mode} ])	Number	add key sequence to typeahead buffer
filecopy({from}, {to})	Number	TRUE if copying file {from} to {to} worked
filereadable({file})	Number	TRUE if {file} is a readable file
filewritable({file})	Number	TRUE if {file} is a writable file
filter({expr1}, {expr2})	List/Dict/Blob/String	remove items from {expr1} where {expr2} is 0
finddir({name} [, {path} [, {count} ]])	String	find directory {name} in {path}
findfile({name} [, {path} [, {count} ]])	String	find file {name} in {path}
flatten({list} [, {maxdepth} ])	List	flatten {list} up to {maxdepth} levels
flattennew({list} [, {maxdepth} ])	List	flatten a copy of {list}
float2nr({expr})	Number	convert Float {expr} to a Number
floor({expr})	Float	round {expr} down
fmod({expr1}, {expr2})	Float	remainder of {expr1} / {expr2}
fnameescape({fname})	String	escape special characters in {fname}
fnamemodify({fname}, {mods})	String	modify file name
foldclosed({lnum})	Number	first line of fold at {lnum} if closed
foldclosedend({lnum})	Number	last line of fold at {lnum} if closed
foldlevel({lnum})	Number	fold level at {lnum}
foldtext()	String	line displayed for closed fold
foldtextresult({lnum})	String	text for closed fold at {lnum}
foreach({expr1}, {expr2})	List/Dict/Blob/String	for each item in {expr1} call {expr2}
foreground()	Number	bring the Vim window to the foreground
fullcommand({name} [, {vim9} ])	String	get full command from {name}
funcref({name} [, {arglist} ] [, {dict} ])	Funcref	reference to function {name}
function({name} [, {arglist} ] [, {dict} ])		

garbagecollect([ <a href="#">{atexit}</a> ])	Funcref	named reference to function <a href="#">{name}</a>
get( <a href="#">{list}</a> , <a href="#">{idx}</a> [, <a href="#">{def}</a> ])	none	free memory, breaking cyclic references
get( <a href="#">{dict}</a> , <a href="#">{key}</a> [, <a href="#">{def}</a> ])	any	get item <a href="#">{idx}</a> from <a href="#">{list}</a> or <a href="#">{def}</a>
get( <a href="#">{func}</a> , <a href="#">{what}</a> )	any	get item <a href="#">{key}</a> from <a href="#">{dict}</a> or <a href="#">{def}</a>
getbufinfo([ <a href="#">{buf}</a> ])	any	get property of funcref/partial <a href="#">{func}</a>
getbufline( <a href="#">{buf}</a> , <a href="#">{lnum}</a> [, <a href="#">{end}</a> ])	List	information about buffers
getbufoneline( <a href="#">{buf}</a> , <a href="#">{lnum}</a> )	List	lines <a href="#">{lnum}</a> to <a href="#">{end}</a> of buffer <a href="#">{buf}</a>
getbufvar( <a href="#">{buf}</a> , <a href="#">{varname}</a> [, <a href="#">{def}</a> ])	String	line <a href="#">{lnum}</a> of buffer <a href="#">{buf}</a>
getcellpixels()	any	variable <a href="#">{varname}</a> in buffer <a href="#">{buf}</a>
getcellwidths()	List	get character cell pixel size
getchangelist([ <a href="#">{buf}</a> ])	List	get character cell width overrides
getchar([ <a href="#">{expr}</a> [, <a href="#">{opts}</a> ]])	List	list of change list items
getcharmod()	Number or String	get one character from the user
getcharpos( <a href="#">{expr}</a> )	Number	modifiers for the last typed character
getcharsearch()	List	position of cursor, mark, etc.
getcharstr([ <a href="#">{expr}</a> [, <a href="#">{opts}</a> ]])	Dict	last character search
getcmdcomplpat()	String	get one character from the user
getcmdcompltype()	String	return the completion pattern of the current command-line completion
getcmdline()	String	return the type of the current command-line completion
getcmdpos()	String	return the current command-line input
getcmdprompt()	Number	return cursor position in command-line
getcmdscreenpos()	String	return the current command-line prompt
getcmdtype()	Number	return cursor screen position in command-line
getcmdwintype()	String	return current command-line type
getcompletion( <a href="#">{pat}</a> , <a href="#">{type}</a> [, <a href="#">{filtered}</a> ])	String	return current command-line window type
getcurpos([ <a href="#">{winnr}</a> ])	List	list of cmdline completion matches
getcursorcharpos([ <a href="#">{winnr}</a> ])	List	position of the cursor
getcwd([ <a href="#">{winnr}</a> [, <a href="#">{tabnr}</a> ]])	List	character position of the cursor
getenv( <a href="#">{name}</a> )	String	get the current working directory
getfontname([ <a href="#">{name}</a> ])	String	return environment variable
getfperm( <a href="#">{fname}</a> )	String	name of font being used
getfsize( <a href="#">{fname}</a> )	String	file permissions of file <a href="#">{fname}</a>
getftime( <a href="#">{fname}</a> )	Number	size in bytes of file <a href="#">{fname}</a>
getftype( <a href="#">{fname}</a> )	Number	last modification time of file
getimstatus()	String	description of type of file <a href="#">{fname}</a>
getjumplist([ <a href="#">{winnr}</a> [, <a href="#">{tabnr}</a> ]])	Number	<b>TRUE</b> if the IME status is active
getline( <a href="#">{lnum}</a> )	List	list of jump list items
getline( <a href="#">{lnum}</a> , <a href="#">{end}</a> )	String	line <a href="#">{lnum}</a> of current buffer
getloclist( <a href="#">{nr}</a> )	List	lines <a href="#">{lnum}</a> to <a href="#">{end}</a> of current buffer
getloclist( <a href="#">{nr}</a> , <a href="#">{what}</a> )	List	list of location list items
getmarklist([ <a href="#">{buf}</a> ])	Dict	get specific location list properties
getmatches([ <a href="#">{win}</a> ])	List	list of global/local marks
getmousepos()	List	list of current matches
getmousetype()	Dict	last known mouse position
getmousepos()	String	current mouse shape name
getpid()	Number	process ID of Vim

getpos({expr})	List	position of cursor, mark, etc.
getqflist()	List	list of quickfix items
getqflist({what})	Dict	get specific quickfix list properties
getreg([{{regname}} [, 1 [, {{list}}]])	String or List	contents of a register
getreginfo([{{regname}}])	Dict	information about a register
getregion({pos1}, {{pos2}} [, {{opts}}])	List	get the text from {{pos1}} to {{pos2}}
getregionpos({pos1}, {{pos2}} [, {{opts}}])	List	get a list of positions for a region
getregtype([{{regname}}])	String	type of a register
getscriptinfo([{{opts}}])	List	list of sourced scripts
getstacktrace()	List	get current stack trace of Vim scripts
gettabinfo([{{expr}}])	List	list of tab pages
gettabvar({nr}, {{varname}} [, {{def}}])	any	variable {{varname}} in tab {{nr}} or {{def}}
gettabwinvar({tabnr}, {{winnr}}, {{name}} [, {{def}}])	any	{{name}} in {{winnr}} in tab page {{tabnr}}
gettagstack([{{nr}}])	Dict	get the tag stack of window {{nr}}
gettext({text} [, {{package}}])	String	lookup translation of {{text}}
getwininfo([{{winid}}])	List	list of info about each window
getwinpos([{{timeout}}])	List	X and Y coord in pixels of Vim window
getwinposx()	Number	X coord in pixels of the Vim window
getwinposy()	Number	Y coord in pixels of the Vim window
getwinvar({nr}, {{varname}} [, {{def}}])	any	variable {{varname}} in window {{nr}}
glob({expr} [, {{nosuf}} [, {{list}} [, {{alllinks}}]])	any	expand file wildcards in {{expr}}
glob2regpat({expr})	String	convert a glob pat into a search pat
globpath({path}, {{expr}} [, {{nosuf}} [, {{list}} [, {{alllinks}}]])	String	do glob({expr}) for all dirs in {{path}}
has({feature} [, {{check}}])	Number	TRUE if feature {{feature}} supported
has_key({dict}, {{key}})	Number	TRUE if {{dict}} has entry {{key}}
haslocaldir([{{winnr}} [, {{tabnr}}]])	Number	TRUE if the window executed :lcd or :tcd
hasmapto({what} [, {{mode}} [, {{abbr}}])	Number	TRUE if mapping to {{what}} exists
histadd({history}, {{item}})	Number	add an item to a history
histdel({history} [, {{item}}])	Number	remove an item from a history
histget({history} [, {{index}}])	String	get the item {{index}} from a history
histnr({history})	Number	highest index of a history
hlID({name})	Number	syntax ID of highlight group {{name}}
hlexists({name})	Number	TRUE if highlight group {{name}} exists
hlget([{{name}} [, {{resolve}}])	List	get highlight group attributes
hlset({list})	Number	set highlight group attributes
hostname()	String	name of the machine Vim is running on
iconv({expr}, {{from}}, {{to}})	String	convert encoding of {{expr}}
id({item})	String	get unique identity string of item
indent({lnum})	Number	indent of line {{lnum}}
index({object}, {{expr}} [, {{start}} [, {{ic}}])	Number	index in {{object}} where {{expr}} appears
indexof({object}, {{expr}} [, {{opts}}])	Number	index in {{object}} where {{expr}} is true

input({prompt} [, {text} [, {completion}]])	String	get input from the user
inputdialog({prompt} [, {text} [, {cancelreturn}]])	String	like input() but in a GUI dialog
inputlist({textlist})	Number	let the user pick from a choice list
inputrestore()	Number	restore typeahead
inputsave()	Number	save and clear typeahead
inputsecret({prompt} [, {text}])	String	like input() but hiding the text
insert({object}, {item} [, {idx}])	List	insert {item} in {object} [before {idx}]
instanceof({object}, {class})	Number	TRUE if {object} is an instance of {class}
interrupt()	none	interrupt script execution
invert({expr})	Number	bitwise invert
isabsolutePath({path})	Number	TRUE if {path} is an absolute path
isDirectory({directory})	Number	TRUE if {directory} is a directory
isinf({expr})	Number	determine if {expr} is infinity value (positive or negative)
islocked({expr})	Number	TRUE if {expr} is locked
isnan({expr})	Number	TRUE if {expr} is NaN
items({dict})	List	key-value pairs in {dict}
job_getchannel({job})	Channel	get the channel handle for {job}
job_info([{job}])	Dict	get information about {job}
job_setoptions({job}, {options})	none	set options for {job}
job_start({command} [, {options}])	Job	start a job
job_status({job})	String	get the status of {job}
job_stop({job} [, {how}])	Number	stop {job}
join({list} [, {sep}])	String	join {list} items into one String
js_decode({string})	any	decode JS style JSON
js_encode({expr})	String	encode JS style JSON
json_decode({string})	any	decode JSON
json_encode({expr})	String	encode JSON
keys({dict})	List	keys in {dict}
keytrans({string})	String	translate internal keycodes to a form that can be used by :map
len({expr})	Number	the length of {expr}
libcall({lib}, {func}, {arg})	String	call {func} in library {lib} with {arg}
libcallnr({lib}, {func}, {arg})	Number	idem, but return a Number
line({expr} [, {winid}])	Number	line nr of cursor, last line or mark
line2byte({lnum})	Number	byte count of line {lnum}
lispindent({lnum})	Number	Lisp indent for line {lnum}
list2blob({list})	Blob	turn {list} of numbers into a Blob
list2str({list} [, {utf8}])	String	turn {list} of numbers into a String
listener_add({callback} [, {buf}])	Number	add a callback to listen to changes
listener_flush([{buf}])	none	invoke listener callbacks
listener_remove({id})	none	remove a listener callback
localtime()	Number	current time
log({expr})	Float	natural logarithm (base e) of {expr}
log10({expr})	Float	logarithm of Float {expr} to base 10
luaeval({expr} [, {expr}])	any	evaluate Lua expression
map({expr1}, {expr2})	List/Dict/Blob/String	change each item in {expr1} to {expr2}
maparg({name} [, {mode} [, {abbr} [, {dict}]]])	String or Dict	

		rhs of mapping {name} in mode {mode}
mapcheck({name} [, {mode} [, {abbr}]])		
	String	check for mappings matching {name}
maplist([{abbr}])	List	list of all mappings, a dict for each
mapnew({expr1}, {expr2})	List/Dict/Blob/String	
		like map() but creates a new List or Dictionary
mapset({mode}, {abbr}, {dict})	none	restore mapping from maparg() result
match({expr}, {pat} [, {start} [, {count}]])	Number	position where {pat} matches in {expr}
matchadd({group}, {pattern} [, {priority} [, {id} [, {dict}]]])	Number	highlight {pattern} with {group}
matchaddpos({group}, {pos} [, {priority} [, {id} [, {dict}]]])	Number	highlight positions with {group}
matcharg({nr})	List	arguments of :match
matchbuflines({buf}, {pat}, {lnum}, {end}, [, {dict}])	List	all the {pat} matches in buffer {buf}
matchdelete({id} [, {win}])	Number	delete match identified by {id}
matchend({expr}, {pat} [, {start} [, {count}]])	Number	position where {pat} ends in {expr}
matchfuzzy({list}, {str} [, {dict}])	List	fuzzy match {str} in {list}
matchfuzzypos({list}, {str} [, {dict}])	List	fuzzy match {str} in {list}
matchlist({expr}, {pat} [, {start} [, {count}]])	List	match and submatches of {pat} in {expr}
matchstr({expr}, {pat} [, {start} [, {count}]])	String	{count}'th match of {pat} in {expr}
matchstrlist({list}, {pat} [, {dict}])	List	all the {pat} matches in {list}
matchstrpos({expr}, {pat} [, {start} [, {count}]])	List	{count}'th match of {pat} in {expr}
max({expr})	Number	maximum value of items in {expr}
menu_info({name} [, {mode}])	Dict	get menu item information
min({expr})	Number	minimum value of items in {expr}
mkdir({name} [, {flags} [, {prot}]])	Number	create directory {name}
mode([{expr}])	String	current editing mode
mzeval({expr})	any	evaluate MzScheme expression
nextnonblank({lnum})	Number	line nr of non-blank line >= {lnum}
ngettext({single}, {plural}, {number}[, {domain}])	String	translate text based on {number}
nr2char({expr} [, {utf8}])	String	single char with ASCII/UTF-8 value {expr}
or({expr}, {expr})	Number	bitwise OR
pathshorten({expr} [, {len}])	String	shorten directory names in a path
perlevel({expr})	any	evaluate Perl expression
popup_atcursor({what}, {options})	Number	create popup window near the cursor
popup_beval({what}, {options})	Number	create popup window for 'ballooneval'
popup_clear()	none	close all popup windows
popup_close({id} [, {result}])	none	close popup window {id}
popup_create({what}, {options})	Number	create a popup window
popup_dialog({what}, {options})	Number	create a popup window used as a dialog
popup_filter_menu({id}, {key})	Number	filter for a menu popup window
popup_filter_yesno({id}, {key})	Number	filter for a dialog popup window

popup_findecho()	Number	get window ID of popup for <code>:echowin`</code>
popup_findinfo()	Number	get window ID of info popup window
popup_findpreview()	Number	get window ID of preview popup window
popup_getoptions({id})	Dict	get options of popup window <code>{id}</code>
popup_getpos({id})	Dict	get position of popup window <code>{id}</code>
popup_hide({id})	none	hide popup menu <code>{id}</code>
popup_list()	List	get a list of window IDs of all popups
popup_locate({row}, {col})	Number	get window ID of popup at position
popup_menu({what}, {options})	Number	create a popup window used as a menu
popup_move({id}, {options})	none	set position of popup window <code>{id}</code>
popup_notification({what}, {options})	Number	create a notification popup window
popup_setbuf({id}, {buf})	Bool	set the buffer for the popup window <code>{id}</code>
popup_setoptions({id}, {options})	none	set options for popup window <code>{id}</code>
popup_settext({id}, {text})	none	set the text of popup window <code>{id}</code>
popup_show({id})	none	unhide popup window <code>{id}</code>
pow({x}, {y})	Float	<code>{x}</code> to the power of <code>{y}</code>
prevnonblank({lnum})	Number	line nr of non-blank line $\leq$ <code>{lnum}</code>
printf({fmt}, {expr1}...)	String	format text
prompt_getprompt({buf})	String	get prompt text
prompt_setcallback({buf}, {expr})	none	set prompt callback function
prompt_setinterrupt({buf}, {text})	none	set prompt interrupt function
prompt_setprompt({buf}, {text})	none	set prompt text
prop_add({lnum}, {col}, {props})	none	add one text property
prop_add_list({props}, [[{lnum}, {col}, {end-lnum}, {end-col}], ...])	none	add multiple text properties
prop_clear({lnum} [, {lnum-end} [, {props}]])	none	remove all text properties
prop_find({props} [, {direction}])	Dict	search for a text property
prop_list({lnum} [, {props}])	List	text properties in <code>{lnum}</code>
prop_remove({props} [, {lnum} [, {lnum-end}]])	Number	remove a text property
prop_type_add({name}, {props})	none	define a new property type
prop_type_change({name}, {props})	none	change an existing property type
prop_type_delete({name} [, {props}])	none	delete a property type
prop_type_get({name} [, {props}])	Dict	get property type values
prop_type_list([{props}])	List	get list of property types
pum_getpos()	Dict	position and size of pum if visible
pumvisible()	Number	whether popup menu is visible
py3eval({expr} [, {locals}])	any	evaluate <code>python3</code> expression
pyeval({expr} [, {locals}])	any	evaluate <code>Python</code> expression
pyxeval({expr} [, {locals}])	any	evaluate <code>python_x</code> expression
rand([{expr}])	Number	get pseudo-random number
range({expr} [, {max} [, {stride}])	List	items from <code>{expr}</code> to <code>{max}</code>
readblob({fname} [, {offset} [, {size}])	Blob	read a <code>Blob</code> from <code>{fname}</code>
readdir({dir} [, {expr} [, {dict}])	List	file names in <code>{dir}</code> selected by <code>{expr}</code>

```

readdirx({dir} [, {expr} [, {dict}]]))
 List file info in {dir} selected by {expr}
readfile({fname} [, {type} [, {max}]]))
 List get list of lines from file {fname}
reduce({object}, {func} [, {initial}])
 any reduce {object} using {func}
reg_executing()
 String get the executing register name
reg_recording()
 String get the recording register name
reltime([{{start} [, {end}]]])
 List get time value
reltimefloat({time})
 Float turn the time value into a Float
reltimestr({time})
 String turn time value into a String
remote_expr({server}, {string} [, {idvar} [, {timeout}]]))
 String send expression
remote_foreground({server})
 Number bring Vim server to the foreground
remote_peek({serverid} [, {retvar}])
 Number check for reply string
remote_read({serverid} [, {timeout}])
 String read reply string
remote_send({server}, {string} [, {idvar}])
 String send key sequence
remote_startserver({name})
 none become server {name}
remove({list}, {idx} [, {end}])
 any/List remove items {idx}-{end} from {list}
remove({blob}, {idx} [, {end}])
 Number/Blob remove bytes {idx}-{end} from {blob}
remove({dict}, {key})
 any remove entry {key} from {dict}
rename({from}, {to})
 Number rename (move) file from {from} to {to}
repeat({expr}, {count})
 List/Blob/String repeat {expr} {count} times
resolve({filename})
 String get filename a shortcut points to
reverse({obj})
 List/Blob/String reverse {obj}
round({expr})
 Float round off {expr}
rubyeval({expr})
 any evaluate Ruby expression
screenattr({row}, {col})
 Number attribute at screen position
screenchar({row}, {col})
 Number character at screen position
screenchars({row}, {col})
 List List of characters at screen position
screencol()
 Number current cursor column
screenpos({winid}, {lnum}, {col})
 Dict screen row and col of a text character
screenrow()
 Number current cursor row
screenstring({row}, {col})
 String characters at screen position
search({pattern} [, {flags} [, {stoptime} [, {timeout} [, {skip}]]]])
 Number search for {pattern}
searchcount([{{options}}])
 Dict get or update search stats
searchdecl({name} [, {global} [, {thisblock}]]))
 Number search for variable declaration
searchpair({start}, {middle}, {end} [, {flags} [, {skip} [...]]])
 Number search for other end of start/end pair
searchpairpos({start}, {middle}, {end} [, {flags} [, {skip} [...]]])
 List search for other end of start/end pair
searchpos({pattern} [, {flags} [, {stoptime} [, {timeout} [, {skip}]]]])
 List search for {pattern}
server2client({clientid}, {string})
 Number send reply string

```

serverlist()	String	get a list of available servers
setbufline({buf}, {lnum}, {text})	Number	set line {lnum} to {text} in buffer {buf}
setbufvar({buf}, {varname}, {val})	none	set {varname} in buffer {buf} to {val}
setcellwidths({list})	none	set character cell width overrides
setcharpos({expr}, {list})	Number	set the {expr} position to {list}
setcharcharpos({dict})	Dict	set character search from {dict}
setcmdline({str} [, {pos}])	Number	set command-line
setcmdpos({pos})	Number	set cursor position in command-line
setcursorcharpos({list})	Number	move cursor to position in {list}
setenv({name}, {val})	none	set environment variable
setfperm({fname}, {mode})	Number	set {fname} file permissions to {mode}
setline({lnum}, {line})	Number	set line {lnum} to {line}
setloclist({nr}, {list} [, {action}])	Number	modify location list using {list}
setloclist({nr}, {list}, {action}, {what})	Number	modify specific location list props
setmatches({list} [, {win}])	Number	restore a list of matches
setpos({expr}, {list})	Number	set the {expr} position to {list}
setqflist({list} [, {action}])	Number	modify quickfix list using {list}
setqflist({list}, {action}, {what})	Number	modify specific quickfix list props
setreg({n}, {v} [, {opt}])	Number	set register to value and type
settabvar({nr}, {varname}, {val})	none	set {varname} in tab page {nr} to {val}
settabwinvar({tabnr}, {winnr}, {varname}, {val})	none	set {varname} in window {winnr} in tab page {tabnr} to {val}
settagstack({nr}, {dict} [, {action}])	Number	modify tag stack using {dict}
setwinvar({nr}, {varname}, {val})	none	set {varname} in window {nr} to {val}
sha256({string})	String	SHA256 checksum of {string}
shellescape({string} [, {special}])	String	escape {string} for use as shell command argument
shiftwidth([ {col} ])	Number	effective value of 'shiftwidth'
sign_define({name} [, {dict}])	Number	define or update a sign
sign_define({list})	List	define or update a list of signs
sign_getdefined([ {name} ])	List	get a list of defined signs
sign_getplaced([ {buf} [, {dict} ]])	List	get a list of placed signs
sign_jump({id}, {group}, {buf})	Number	jump to a sign
sign_place({id}, {group}, {name}, {buf} [, {dict}])	Number	place a sign
sign_placelist({list})	List	place a list of signs
sign_undefine([ {name} ])	Number	undefine a sign
sign_undefine({list})	List	undefine a list of signs
sign_unplace({group} [, {dict}])	Number	unplace a sign
sign_unplacelist({list})	List	unplace a list of signs
simplify({filename})	String	simplify filename as much as possible
sin({expr})	Float	sine of {expr}

sinh({expr})	Float	hyperbolic sine of {expr}
slice({expr}, {start} [, {end}])	String, List or Blob	slice of a String, List or Blob
sort({list} [, {how} [, {dict}])	List	sort {list}, compare with {how}
sound_clear()	none	stop playing all sounds
sound_playevent({name} [, {callback}])	Number	play an event sound
sound_playfile({path} [, {callback}])	Number	play sound file {path}
sound_stop({id})	none	stop playing sound {id}
soundfold({word})	String	sound-fold {word}
spellbadword()	String	badly spelled word at cursor
spellsuggest({word} [, {max} [, {capital}])	List	spelling suggestions
split({expr} [, {pat} [, {keepempty}])	List	make List from {pat} separated {expr}
sqrt({expr})	Float	square root of {expr}
srand([{expr}])	List	get seed for rand()
state([{what}])	String	current state of Vim
str2blob({list} [, {options}])	Blob	convert list of strings into a Blob
str2float({expr} [, {quoted}])	Float	convert String to Float
str2list({expr} [, {utf8}])	List	convert each character of {expr} to ASCII/UTF-8 value
str2nr({expr} [, {base} [, {quoted}])	Number	convert String to Number
strcharlen({expr})	Number	character length of the String {expr}
strcharpart({str}, {start} [, {len} [, {skipcc}])	String	{len} characters of {str} at character {start}
strchars({expr} [, {skipcc}])	Number	character count of the String {expr}
strdisplaywidth({expr} [, {col}])	Number	display length of the String {expr}
strftime({format} [, {time}])	String	format time with a specified format
strgetchar({str}, {index})	Number	get char {index} from {str}
stridx({haystack}, {needle} [, {start}])	Number	index of {needle} in {haystack}
string({expr})	String	String representation of {expr} value
strlen({expr})	Number	length of the String {expr}
strpart({str}, {start} [, {len} [, {chars}])	String	{len} bytes/chars of {str} at byte {start}
strptime({format}, {timestring})	Number	Convert {timestring} to unix timestamp
strridx({haystack}, {needle} [, {start}])	Number	last index of {needle} in {haystack}
strtrans({expr})	String	translate string to make it printable
strutf16len({string} [, {countcc}])	Number	number of UTF-16 code units in {string}
strwidth({expr})	Number	display cell length of the String {expr}
submatch({nr} [, {list}])	String or List	specific match in ":s" or substitute()
substitute({expr}, {pat}, {sub}, {flags})	String	all {pat} in {expr} replaced with {sub}
swapfilelist()	List	swap files found in 'directory'

swapinfo({fname})	Dict	information about swap file {fname}
swapname({buf})	String	swap file of buffer {buf}
synID({lnum}, {col}, {trans})	Number	syntax ID at {lnum} and {col}
synIDattr({synID}, {what} [, {mode}])	String	attribute {what} of syntax ID {synID}
synIDtrans({synID})	Number	translated syntax ID of {synID}
synconcealed({lnum}, {col})	List	info about concealing
synstack({lnum}, {col})	List	stack of syntax IDs at {lnum} and {col}
system({expr} [, {input}])	String	output of shell command/filter {expr}
systemlist({expr} [, {input}])	List	output of shell command/filter {expr}
tabpagebuflist([ {arg} ])	List	list of buffer numbers in tab page
tabpagenr([ {arg} ])	Number	number of current or last tab page
tabpagewinnr({tabarg} [, {arg}])	Number	number of current window in tab page
tagfiles()	List	tags files used
taglist({expr} [, {filename}])	List	list of tags matching {expr}
tan({expr})	Float	tangent of {expr}
tanh({expr})	Float	hyperbolic tangent of {expr}
tempname()	String	name for a temporary file
term_dumpdiff({filename}, {filename} [, {options}])	Number	display difference between two dumps
term_dumpload({filename} [, {options}])	Number	displaying a screen dump
term_dumpwrite({buf}, {filename} [, {options}])	none	dump terminal window contents
term_getaltscreen({buf})	Number	get the alternate screen flag
term_getansicolors({buf})	List	get ANSI palette in GUI color mode
term_getattr({attr}, {what})	Number	get the value of attribute {what}
term_getcursor({buf})	List	get the cursor position of a terminal
term_getjob({buf})	Job	get the job associated with a terminal
term_getline({buf}, {row})	String	get a line of text from a terminal
term_getscrolled({buf})	Number	get the scroll count of a terminal
term_getsize({buf})	List	get the size of a terminal
term_getstatus({buf})	String	get the status of a terminal
term_gettitle({buf})	String	get the title of a terminal
term_gettty({buf}, [ {input} ])	String	get the tty name of a terminal
term_list()	List	get the list of terminal buffers
term_scrape({buf}, {row})	List	get row of a terminal screen
term_sendkeys({buf}, {keys})	none	send keystrokes to a terminal
term_setansicolors({buf}, {colors})	none	set ANSI palette in GUI color mode
term_setapi({buf}, {expr})	none	set <code>terminal-api</code> function name prefix
term_setkill({buf}, {how})	none	set signal to stop job in terminal
term_setrestore({buf}, {command})	none	set command to restore terminal
term_setsize({buf}, {rows}, {cols})	none	set the size of a terminal
term_start({cmd} [, {options}])	Number	open a terminal window and run a job
term_wait({buf} [, {time}])	Number	wait for screen to be updated
terminalprops()	Dict	properties of the terminal
test_alloc_fail({id}, {countdown}, {repeat})	none	make memory allocation fail
test_autochdir()	none	enable <code>'autochdir'</code> during startup
test_feedinput({string})	none	add key sequence to input buffer
test_garbagecollect_now()	none	free memory right now for testing
test_garbagecollect_soon()	none	free memory soon for testing

test_getvalue({string})	any	get value of an internal variable
test_gui_event({event}, {args})	bool	generate a GUI event for testing
test_ignore_error({expr})	none	ignore a specific error
test_mswin_event({event}, {args})	bool	generate MS-Windows event for testing
test_null_blob()	Blob	null value for testing
test_null_channel()	Channel	null value for testing
test_null_dict()	Dict	null value for testing
test_null_function()	Funcref	null value for testing
test_null_job()	Job	null value for testing
test_null_list()	List	null value for testing
test_null_partial()	Funcref	null value for testing
test_null_string()	String	null value for testing
test_option_not_set({name})	none	reset flag indicating option was set
test_override({expr}, {val})	none	test with Vim internal overrides
test_refcount({expr})	Number	get the reference count of {expr}
test_setmouse({row}, {col})	none	set the mouse position for testing
test_settime({expr})	none	set current time for testing
test_srand_seed([seed])	none	set seed for testing srand()
test_unknown()	any	unknown value for testing
test_void()	any	void value for testing
timer_info([id])	List	information about timers
timer_pause({id}, {pause})	none	pause or unpause a timer
timer_start({time}, {callback} [, {options}])	Number	create a timer
timer_stop({timer})	none	stop a timer
timer_stopall()	none	stop all timers
tolower({expr})	String	the String {expr} switched to lowercase
toupper({expr})	String	the String {expr} switched to uppercase
tr({src}, {fromstr}, {tostr})	String	translate chars of {src} in {fromstr} to chars in {tostr}
trim({text} [, {mask} [, {dir}])	String	trim characters in {mask} from {text}
trunc({expr})	Float	truncate Float {expr}
type({expr})	Number	type of value {expr}
typename({expr})	String	representation of the type of {expr}
undofile({name})	String	undo file name for {name}
undotree([buf])	List	undo file tree for buffer {buf}
uniq({list} [, {func} [, {dict}])	List	remove adjacent duplicates from a list
utf16idx({string}, {idx} [, {countcc} [, {charidx}])	Number	UTF-16 index of byte {idx} in {string}
values({dict})	List	values in {dict}
virtcol({expr} [, {list} [, {winid}])	Number or List	screen column of cursor or mark
virtcol2col({winid}, {lnum}, {col})	Number	byte index of a character on screen
visualmode([expr])	String	last visual mode used
wildmenu_mode()	Number	whether 'wildmenu' mode is active
win_execute({id}, {command} [, {silent}])	String	execute {command} in window {id}
win_findbuf({bufnr})	List	find windows containing {bufnr}
win_getid([win] [, {tab}])	Number	get window ID for {win} in {tab}

win_gettype([{nr}])	String	type of window {nr}
win_gotoid({expr})	Number	go to window with ID {expr}
win_id2tabwin({expr})	List	get tab and window nr from window ID
win_id2win({expr})	Number	get window nr from window ID
win_move_separator({nr})	Number	move window vertical separator
win_move_statusline({nr})	Number	move window status line
win_screenpos({nr})	List	get screen position of window {nr}
win_splitmove({nr}, {target} [, {options}])	Number	move window {nr} to split of {target}
winbufnr({nr})	Number	buffer number of window {nr}
wincol()	Number	window column of the cursor
windowsversion()	String	MS-Windows OS version
winheight({nr})	Number	height of window {nr}
winlayout([{tabnr}])	List	layout of windows in tab {tabnr}
winline()	Number	window line of the cursor
winnr([{expr}])	Number	number of current window
winrestcmd()	String	returns command to restore window sizes
winrestview({dict})	none	restore view of current window
winsaveview()	Dict	save view of current window
winwidth({nr})	Number	width of window {nr}
wordcount()	Dict	get byte/char/word statistics
writefile({object}, {fname} [, {flags}])	Number	write Blob or List of lines to file
xor({expr}, {expr})	Number	bitwise XOR

## 2. Details

## builtin-function-details

Not all functions are here, some have been moved to a help file covering the specific functionality.

Return type specifies the type for [Vim9-script](#) , see [vim9-types](#)

abs({expr})

abs()

Return the absolute value of {expr}. When {expr} evaluates to a [Float](#) abs() returns a [Float](#) . When {expr} can be converted to a [Number](#) abs() returns a [Number](#) . Otherwise abs() gives an error message and returns -1.

Examples:

```
echo abs(1.456)
1.456
echo abs(-5.456)
5.456
echo abs(-4)
4
```

Can also be used as a [method](#) :

```
Compute()->abs()
```

Return type: [Number](#) or [Float](#) depending on {expr}

acos({expr})

acos()

Return the arc cosine of {expr} measured in radians, as a [Float](#) in the range of [0, pi].

`{expr}` must evaluate to a `Float` or a `Number` in the range `[-1, 1]`. Otherwise `acos()` returns `"nan"`.

Examples:

```
:echo acos(0)
1.570796
:echo acos(-0.5)
2.094395
```

Can also be used as a `method` :

```
Compute()->acos()
```

Return type: `Float`

`add({object}, {expr})` `add()`

Append the item `{expr}` to `List` or `Blob` `{object}`. Returns the resulting `List` or `Blob` . Examples:

```
:let alist = add([1, 2, 3], item)
:call add(mylist, "woodstock")
```

**Note** that when `{expr}` is a `List` it is appended as a single item. Use `extend()` to concatenate `Lists` .

When `{object}` is a `Blob` then `{expr}` must be a number.

Use `insert()` to add an item at another position.

Returns 1 if `{object}` is not a `List` or a `Blob` .

Can also be used as a `method` :

```
mylist->add(val1)->add(val2)
```

Return type: `list<{type}>` (depending on the given `List` ) or `Blob`

`and({expr}, {expr})` `and()`

Bitwise AND on the two arguments. The arguments are converted to a number. A `List`, `Dict` or `Float` argument causes an error. Also see ``or()`` and ``xor()`` .

Example:

```
:let flag = and(bits, 0x80)
```

Can also be used as a `method` :

```
:let flag = bits->and(0x80)
```

Return type: `Number`

`append({lnum}, {text})` `append()`

When `{text}` is a `List` : Append each item of the `List` as a text line below line `{lnum}` in the current buffer.

Otherwise append `{text}` as one text line below line `{lnum}` in the current buffer.

Any type of item is accepted and converted to a `String`.

`{lnum}` can be zero to insert a line before the first one.

`{lnum}` is used like with `getline()` .

Returns 1 for failure (`{lnum}` out of range or out of memory), 0 for success. When `{text}` is an empty list zero is returned,

no matter the value of `{lnum}`.

In `Vim9` script an invalid argument or negative number results in an error. Example:

```
:let failed = append(line('$'), "# THE END")
:let failed = append(0, ["Chapter 1", "the beginning"])
```

Can also be used as a `method` after a List, the base is passed as the second argument:

```
mylist->append(lnum)
```

Return type: `Number`

`appendbufline({buf}, {lnum}, {text})` `appendbufline()`

Like `append()` but append the text in buffer `{buf}`.

This function works only for loaded buffers. First call `bufload()` if needed.

For the use of `{buf}`, see `bufname()` .

`{lnum}` is the line number to append below. `Note` that using `line()` would use the current buffer, not the one appending to. Use "\$" to append at the end of the buffer. Other string values are not supported.

On success 0 is returned, on failure 1 is returned.

In `Vim9` script an error is given for an invalid `{lnum}`.

If `{buf}` is not a valid buffer or `{lnum}` is not valid, an error message is given. Example:

```
:let failed = appendbufline(13, 0, "# THE START")
```

However, when `{text}` is an empty list then no error is given for an invalid `{lnum}`, since `{lnum}` isn't actually used.

Can also be used as a `method` after a List, the base is passed as the second argument:

```
mylist->appendbufline(buf, lnum)
```

Return type: `Number`

`argc([winid])` `argc()`

The result is the number of files in the argument list. See `arglist` .

If `{winid}` is not supplied, the argument list of the current window is used.

If `{winid}` is -1, the global argument list is used.

Otherwise `{winid}` specifies the window of which the argument list is used: either the window number or the window ID.

Returns -1 if the `{winid}` argument is invalid.

Return type: `Number`

`argidx()` `argidx()`  
The result is the current index in the argument list. 0 is the first file. `argc() - 1` is the last one. See `arglist` .

Return type: `Number`

`arglistid([winnr] [, tabnr])` `arglistid()`  
Return the argument list ID. This is a number which identifies the argument list being used. Zero is used for the global argument list. See `arglist` .  
Returns -1 if the arguments are invalid.

Without arguments use the current window.

With `{winnr}` only use this window in the current tab page.

With `{winnr}` and `{tabnr}` use the window in the specified tab page.

`{winnr}` can be the window number or the `window-ID` .

Return type: `Number`

`argv([nr] [, winid])` `argv()`  
The result is the `{nr}`th file in the argument list. See `arglist` . "`argv(0)`" is the first one. Example:

```
:let i = 0
:while i < argc()
: let f = escape(fnameescape(argv(i)), '.')
: exe 'amenu Arg.' .. f .. ' :e ' .. f .. '<CR>'
: let i = i + 1
:endwhile
```

Without the `{nr}` argument, or when `{nr}` is -1, a `List` with the whole `arglist` is returned.

The `{winid}` argument specifies the window ID, see `argc()` .  
For the Vim command line arguments see `v:argv` .

Returns an empty string if `{nr}`th argument is not present in the argument list. Returns an empty List if the `{winid}` argument is invalid.

Return type: `String`

`asin({expr})` `asin()`  
Return the arc sine of `{expr}` measured in radians, as a `Float` in the range of `[-pi/2, pi/2]`.  
`{expr}` must evaluate to a `Float` or a `Number` in the range `[-1, 1]`.  
Returns "nan" if `{expr}` is outside the range `[-1, 1]`. Returns 0.0 if `{expr}` is not a `Float` or a `Number` .  
Examples:

```
:echo asin(0.8)
0.927295
```

```
:echo asin(-0.5)
-0.523599
```

Can also be used as a `method` :  
`Compute()->asin()`

Return type: `Float`

`assert_` functions are documented here: [assert-functions-details](#)

`atan({expr})`

`atan()`

Return the principal value of the arc tangent of `{expr}`, in the range  $[-\pi/2, +\pi/2]$  radians, as a `Float` .

`{expr}` must evaluate to a `Float` or a `Number` .

Returns 0.0 if `{expr}` is not a `Float` or a `Number` .

Examples:

```
:echo atan(100)
1.560797
:echo atan(-4.01)
-1.326405
```

Can also be used as a `method` :  
`Compute()->atan()`

Return type: `Float`

`atan2({expr1}, {expr2})`

`atan2()`

Return the arc tangent of `{expr1}` / `{expr2}`, measured in radians, as a `Float` in the range  $[-\pi, \pi]$ .

`{expr1}` and `{expr2}` must evaluate to a `Float` or a `Number` .

Returns 0.0 if `{expr1}` or `{expr2}` is not a `Float` or a `Number` .

Examples:

```
:echo atan2(-1, 1)
-0.785398
:echo atan2(1, -1)
2.356194
```

Can also be used as a `method` :  
`Compute()->atan2(1)`

Return type: `Float`

`autocmd_add({acmds})`

`autocmd_add()`

Adds a List of autocmds and autocmd groups.

The `{acmds}` argument is a List where each item is a Dict with the following optional items:

<code>bufnr</code>	buffer number to add a buffer-local autocmd. If this item is specified, then the "pattern" item is ignored.
--------------------	-------------------------------------------------------------------------------------------------------------

cmd	Ex command to execute for this autocmd event
event	autocmd event name. Refer to <a href="#">autocmd-events</a> . This can be either a String with a single event name or a List of event names.
group	autocmd group name. Refer to <a href="#">autocmd-groups</a> . If this group doesn't exist then it is created. If not specified or empty, then the default group is used.
nested	boolean flag, set to v:true to add a nested autocmd. Refer to <a href="#">autocmd-nested</a> .
once	boolean flag, set to v:true to add an autocmd which executes only once. Refer to <a href="#">autocmd-once</a> .
pattern	autocmd pattern string. Refer to <a href="#">autocmd-patterns</a> . If "bufnr" item is present, then this item is ignored. This can be a String with a single pattern or a List of patterns.
replace	boolean flag, set to v:true to remove all the commands associated with the specified autocmd event and group and add the {cmd}. This is useful to avoid adding the same command multiple times for an autocmd event in a group.

Returns v:true on success and v:false on failure.

Examples:

```
" Create a buffer-local autocmd for buffer 5
let acmd = {}
let acmd.group = 'MyGroup'
let acmd.event = 'BufEnter'
let acmd.bufnr = 5
let acmd.cmd = 'call BufEnterFunc()'
call autocmd_add([acmd])
```

Can also be used as a [method](#) :

```
GetAutocmdList()->autocmd_add()
```

Return type: [vim9-boolean](#)

`autocmd_delete({acmds})` [autocmd\\_delete\(\)](#)  
Deletes a List of autocmds and autocmd groups.

The {acmds} argument is a List where each item is a Dict with the following optional items:

bufnr	buffer number to delete a buffer-local autocmd. If this item is specified, then the "pattern" item is ignored.
cmd	Ex command for this autocmd event
event	autocmd event name. Refer to <a href="#">autocmd-events</a> . If '*' then all the autocmd events in this group are deleted.
group	autocmd group name. Refer to <a href="#">autocmd-groups</a> . If not specified or empty, then the default

	group is used.
nested	set to v:true for a nested autocmd. Refer to <a href="#">autocmd-nested</a> .
once	set to v:true for an autocmd which executes only once. Refer to <a href="#">autocmd-once</a> .
pattern	autocmd pattern string. Refer to <a href="#">autocmd-patterns</a> . If "bufnr" item is present, then this item is ignored.

If only `{group}` is specified in a `{acmds}` entry and `{event}`, `{pattern}` and `{cmd}` are not specified, then that autocmd group is deleted.

Returns `v:true` on success and `v:false` on failure.

Examples:

```

" :autocmd! BufLeave *.vim
let acmd = #{event: 'BufLeave', pattern: '*.vim'}
call autocmd_delete([acmd])
" :autocmd! MyGroup1 BufLeave
let acmd = #{group: 'MyGroup1', event: 'BufLeave'}
call autocmd_delete([acmd])
" :autocmd! MyGroup2 BufEnter *.c
let acmd = #{group: 'MyGroup2', event: 'BufEnter',
 \ pattern: '*.c'}

" :autocmd! MyGroup2 * *.c
let acmd = #{group: 'MyGroup2', event: '*',
 \ pattern: '*.c'}

call autocmd_delete([acmd])
" :autocmd! MyGroup3
let acmd = #{group: 'MyGroup3'}
call autocmd_delete([acmd])

```

Can also be used as a [method](#) :

```
GetAutocmdList()->autocmd_delete()
```

Return type: `vim9-boolean`

`autocmd_get([opts])`

[autocmd\\_get\(\)](#)

Returns a [List](#) of autocmds. If `{opts}` is not supplied, then returns the autocmds for all the events in all the groups.

The optional `{opts}` Dict argument supports the following items:

group	Autocmd group name. If specified, returns only the autocmds defined in this group. If the specified group doesn't exist, results in an error message. If set to an empty string, then the default autocmd group is used.
event	Autocmd event name. If specified, returns only the autocmds defined for this event. If set to "*", then returns autocmds for all the events. If the specified event doesn't exist, results in an error message.

pattern Autocmd pattern. If specified, returns only the autocmds defined for this pattern.  
A combination of the above three times can be supplied in `{opts}`.

Each Dict in the returned List contains the following items:

bfnr	For buffer-local autocmds, buffer number where the autocmd is defined.
cmd	Command executed for this autocmd.
event	Autocmd event name.
group	Autocmd group name.
nested	Boolean flag, set to <code>v:true</code> for a nested autocmd. See <a href="#">autocmd-nested</a> .
once	Boolean flag, set to <code>v:true</code> , if the autocmd will be executed only once. See <a href="#">autocmd-once</a> .
pattern	Autocmd pattern. For a buffer-local autocmd, this will be of the form " <code>&lt;buffer=n&gt;</code> ".

If there are multiple commands for an autocmd event in a group, then separate items are returned for each command.

Returns an empty List if an autocmd with the specified group or event or pattern is not found.

Examples:

```
" :autocmd MyGroup
echo autocmd_get({group: 'Mygroup'})
" :autocmd G BufUnload
echo autocmd_get({group: 'G', event: 'BufUnload'})
" :autocmd G * *.ts
let acmd = {group: 'G', event: '*', pattern: '*.ts'}
echo autocmd_get(acmd)
" :autocmd Syntax
echo autocmd_get({event: 'Syntax'})
" :autocmd G BufEnter *.ts
let acmd = {group: 'G', event: 'BufEnter',
 \ pattern: '*.ts'}
echo autocmd_get(acmd)
```

Can also be used as a [method](#) :  
`Getopts()->autocmd_get()`

Return type: `list<dict<any>>`

`balloon_gettext()` [balloon\\_gettext\(\)](#)  
Return the current text in the balloon. Only for the string, not used for the List. Returns an empty string if balloon is not present.

Return type: [String](#)

`balloon_show({expr})` [balloon\\_show\(\)](#)  
Show `{expr}` inside the balloon. For the GUI `{expr}` is used as

a string. For a terminal `{expr}` can be a list, which contains the lines of the balloon. If `{expr}` is not a list it will be split with `balloon_split()`. If `{expr}` is an empty string any existing balloon is removed.

Example:

```
func GetBalloonContent()
 " ... initiate getting the content
 return ''
endfunc
set balloonexpr=GetBalloonContent()

func BalloonCallback(result)
 call balloon_show(a:result)
endfunc
```

Can also be used as a `method` :

```
GetText()->balloon_show()
```

The intended use is that fetching the content of the balloon is initiated from `'balloonexpr'`. It will invoke an asynchronous method, in which a callback invokes `balloon_show()`. The `'balloonexpr'` itself can return an empty string or a placeholder, e.g. "loading...".

When showing a balloon is not possible then nothing happens, no error message is given.

{only available when compiled with the `+balloon_eval` or `+balloon_eval_term` feature}

Return type: `Number`

`balloon_split({msg})`

`balloon_split()`

Split String `{msg}` into lines to be displayed in a balloon. The splits are made for the current window size and optimize to show debugger output.

Returns a `List` with the split lines. Returns an empty List on error.

Can also be used as a `method` :

```
GetText()->balloon_split()->balloon_show()
```

{only available when compiled with the `+balloon_eval_term` feature}

Return type: `list<any>` or `list<string>`

`base64_decode({string})`

`base64_decode()`

Return a Blob containing the bytes decoded from the base64 encoded characters in `{string}`.

The `{string}` argument should contain only base64-encoded characters and should have a length that is a multiple of 4.

Returns an empty blob on error.

Examples:

```
" Write the decoded contents to a binary file
call writefile(base64_decode(s), 'tools.bmp')
" Decode a base64-encoded string
echo blob2str(base64_decode(encodedstr))
```

Can also be used as a `method` :

```
GetEncodedString()->base64_decode()
```

Return type: `Blob`

`base64_encode({blob})` `base64_encode()`

Return a base64-encoded String representing the bytes in `{blob}`. The base64 alphabet defined in RFC 4648 is used.

Examples:

```
" Encode the contents of a binary file
echo base64_encode(readblob('somefile.bin'))
" Encode a string
echo base64_encode(str2blob([somestr]))
```

Can also be used as a `method` :

```
GetBinaryData()->base64_encode()
```

Return type: `String`

`bindtextdomain({package}, {path})` `bindtextdomain()`

Bind a specific `{package}` to a `{path}` so that the `gettext()` function can be used to get language-specific translations for a package. `{path}` is the directory name for the translations. See [package-translation](#) .

Returns `v:true` on success and `v:false` on failure (out of memory).

Return type: `vim9-boolean`

`blob2list({blob})` `blob2list()`

Return a List containing the number value of each byte in Blob `{blob}`. Examples:

```
blob2list(0z0102.0304) returns [1, 2, 3, 4]
blob2list(0z) returns []
```

Returns an empty List on error. `list2blob()` does the opposite.

Can also be used as a `method` :

```
GetBlob()->blob2list()
```

Return type: `list<any>` or `list<number>`

`blob2str({blob} [, {options}])` `blob2str()`

Return a List of Strings in the current **'encoding'** by converting the bytes in `{blob}` into characters.

Each `<NL>` byte in the blob is interpreted as the end of a string and a new list item is added. Each `<NUL>` byte in the blob is converted into a `<NL>` character.

If `{options}` is not supplied, the current **'encoding'** value is used to decode the bytes in `{blob}`.

The argument `{options}` is a `Dict` and supports the following items:

`encoding` Decode the bytes in `{blob}` using this encoding. The value is a `String`. See `encoding-names` for the supported values (plus the special value "none").

`E1515`

When current **'encoding'** is "utf-8", an error is given and an empty List is returned if an invalid byte sequence is encountered in `{blob}`. To suppress this validation and get potentially invalid string, set "encoding" in `{options}` to "none".

Returns an empty List if blob is empty.

See also `str2blob()`

Examples:

```
blob2str(@z6162) returns ["ab"]
blob2str(@zC2ABC2BB) returns ["«»"]
blob2str(@zABBB, {'encoding': 'latin1'}) returns ["«»"]
```

Can also be used as a `method` :

```
GetBlob()->blob2str()
```

Return type: `list<string>`

`browse()`

`browse({save}, {title}, {initdir}, {default})`

Put up a file requester. This only works when "has("browse")" returns `TRUE` (only in some GUI versions).

The input fields are:

`{save}` when `TRUE` , select file to write  
`{title}` title for the requester  
`{initdir}` directory to start browsing in  
`{default}` default file name

An empty string is returned when the "Cancel" button is hit, something went wrong, or browsing is not possible.

Return type: `String`

`browsedir({title}, {initdir})` `browsedir()`  
Put up a directory requester. This only works when "has("browse")" returns `TRUE` (only in some GUI versions). On systems where a directory browser is not supported a file browser is used. In that case: select a file in the directory to be used.  
The input fields are:  
    `{title}` title for the requester  
    `{initdir}` directory to start browsing in  
When the "Cancel" button is hit, something went wrong, or browsing is not possible, an empty string is returned.  
  
Return type: `String`

`bufadd({name})` `bufadd()`  
Add a buffer to the buffer list with name `{name}` (must be a String).  
If a buffer for file `{name}` already exists, return that buffer number. Otherwise return the buffer number of the newly created buffer. When `{name}` is an empty string then a new buffer is always created.  
The buffer will not have `'buflisted'` set and not be loaded yet. To add some text to the buffer use this:  
    `let bufnr = bufadd('someName')`  
    `call bufload(bufnr)`  
    `call setbufline(bufnr, 1, ['some', 'text'])`  
Returns 0 on error.  
Can also be used as a `method` :  
    `let bufnr = 'somename'->bufadd()`  
  
Return type: `Number`

`bufexists({buf})` `bufexists()`  
The result is a Number, which is `TRUE` if a buffer called `{buf}` exists.  
If the `{buf}` argument is a number, buffer numbers are used. Number zero is the alternate buffer for the current window.  
  
If the `{buf}` argument is a string it must match a buffer name exactly. The name can be:  
- Relative to the current directory.  
- A full path.  
- The name of a buffer with `'buftype'` set to "nofile".  
- A URL name.  
Unlisted buffers will be found.  
**Note** that help files are listed by their short name in the output of `:buffers` , but `bufexists()` requires using their long name to be able to find them.  
`bufexists()` may report a buffer exists, but to use the name with a `:buffer` command you may need to use `expand()` . Esp for MS-Windows 8.3 names in the form "c:\DOCUME~1"  
Use "`bufexists(0)`" to test for the existence of an alternate

file name.

Can also be used as a **method** :

```
let exists = 'somename'->bufexists()
```

Return type: **Number**

Obsolete name: `buffer_exists()`. `buffer_exists()`

`buflisted({buf})` `buflisted()`

The result is a **Number**, which is **TRUE** if a buffer called `{buf}` exists and is listed (has the **'buflisted'** option set). The `{buf}` argument is used like with `bufexists()` .

Can also be used as a **method** :

```
let listed = 'somename'->buflisted()
```

Return type: **Number**

`bufload({buf})` `bufload()`

Ensure the buffer `{buf}` is loaded. When the buffer name refers to an existing file then the file is read. Otherwise the buffer will be empty. If the buffer was already loaded then there is no change. If the buffer is not related to a file then no file is read (e.g., when **'buftype'** is "nofile"). If there is an existing swap file for the file of the buffer, there will be no dialog, the buffer will be loaded anyway. The `{buf}` argument is used like with `bufexists()` .

Can also be used as a **method** :

```
eval 'somename'->bufload()
```

Return type: **Number**

`bufloaded({buf})` `bufloaded()`

The result is a **Number**, which is **TRUE** if a buffer called `{buf}` exists and is loaded (shown in a window or hidden). The `{buf}` argument is used like with `bufexists()` .

Can also be used as a **method** :

```
let loaded = 'somename'->bufloaded()
```

Return type: **Number**

`bufname([ {buf} ])` `bufname()`

The result is the name of a buffer. Mostly as it is displayed by the ``:ls`` command, but not using special names such as "[No Name]".

If `{buf}` is omitted the current buffer is used.

If `{buf}` is a **Number**, that buffer number's name is given.

Number zero is the alternate buffer for the current window. If {buf} is a String, it is used as a `file-pattern` to match with the buffer names. This is always done like `'magic'` is set and `'coptions'` is empty. When there is more than one match an empty string is returned.

"" or "%" can be used for the current buffer, "#" for the alternate buffer.

A full match is preferred, otherwise a match at the start, end or middle of the buffer name is accepted. If you only want a full match then put "^" at the start and "\$" at the end of the pattern.

Listed buffers are found first. If there is a single match with a listed buffer, that one is returned. Next unlisted buffers are searched for.

If the {buf} is a String, but you want to use it as a buffer number, force it to be a Number by adding zero to it:

```
:echo bufname("3" + 0)
```

Can also be used as a `method` :

```
echo bufnr->bufname()
```

If the buffer doesn't exist, or doesn't have a name, an empty string is returned.

```
bufname("#") alternate buffer name
bufname(3) name of buffer 3
bufname("%") name of current buffer
bufname("file2") name of buffer where "file2" matches.
```

Return type: `String`

`buffer_name()`

Obsolete name: `buffer_name()`.

```
bufnr([{buf} [, {create}]])
```

`bufnr()`

The result is the number of a buffer, as it is displayed by the `:ls` command. For the use of {buf}, see `bufname()` above.

If the buffer doesn't exist, -1 is returned. Or, if the {create} argument is present and TRUE, a new, unlisted, buffer is created and its number is returned. Example:

```
let newbuf = bufnr('Scratch001', 1)
```

Using an empty name uses the current buffer. To create a new buffer with an empty name use `bufadd()` .

`bufnr("$")` is the last buffer:

```
:let last_buffer = bufnr("$")
```

The result is a Number, which is the highest buffer number of existing buffers. **Note** that not all buffers with a smaller number necessarily exist, because `":bwipeout"` may have removed them. Use `bufexists()` to test for the existence of a buffer.

Can also be used as a `method` :

```
echo bufref->bufnr()
```

Return type: `Number`

Obsolete name: `buffer_number()`. `buffer_number()`  
`last_buffer_nr()`

Obsolete name for `bufnr("$")`: `last_buffer_nr()`.

`bufwinid({buf})`

`bufwinid()`

The result is a `Number`, which is the `window-ID` of the first window associated with buffer `{buf}`. For the use of `{buf}`, see `bufname()` above. If buffer `{buf}` doesn't exist or there is no such window, `-1` is returned. Example:

```
echo "A window containing buffer 1 is " .. (bufwinid(1))
```

Only deals with the current tab page. See `win_findbuf()` for finding more.

Can also be used as a `method` :  
`FindBuffer()->bufwinid()`

Return type: `Number`

`bufwinnr({buf})`

`bufwinnr()`

Like `bufwinid()` but return the window number instead of the `window-ID`.  
If buffer `{buf}` doesn't exist or there is no such window, `-1` is returned. Example:

```
echo "A window containing buffer 1 is " .. (bufwinnr(1))
```

The number can be used with `CTRL-W_w` and `":wincmd w"  
:wincmd`.

Can also be used as a `method` :  
`FindBuffer()->bufwinnr()`

Return type: `Number`

`byte2line({byte})`

`byte2line()`

Return the line number that contains the character at byte count `{byte}` in the current buffer. This includes the end-of-line character, depending on the `'fileformat'` option for the current buffer. The first character has byte count one.

Also see `line2byte()`, `go` and `:goto`.

Returns `-1` if the `{byte}` value is invalid.

Can also be used as a `method` :  
`GetOffset()->byte2line()`

Return type: `Number`

{not available when compiled without the `+byte_offset` feature}

`byteidx({expr}, {nr} [, {utf16}])` `byteidx()`

Return byte index of the `{nr}`'th character in the String `{expr}`. Use zero for the first character, it then returns zero.

If there are no multibyte characters the returned value is equal to `{nr}`.

Composing characters are not counted separately, their byte length is added to the preceding base character. See `byteidxcomp()` below for counting composing characters separately.

When `{utf16}` is present and TRUE, `{nr}` is used as the UTF-16 index in the String `{expr}` instead of as the character index. The UTF-16 index is the index in the string when it is encoded with 16-bit words. If the specified UTF-16 index is in the middle of a character (e.g. in a 4-byte character), then the byte index of the first byte in the character is returned. Refer to [string-offset-encoding](#) for more information.

Example :

```
echo matchstr(str, ".", byteidx(str, 3))
```

will display the fourth character. Another way to do the same:

```
let s = strpart(str, byteidx(str, 3))
echo strpart(s, 0, byteidx(s, 1))
```

Also see `strgetchar()` and `strcharpart()` .

If there are less than `{nr}` characters -1 is returned.

If there are exactly `{nr}` characters the length of the string in bytes is returned.

See `charidx()` and `utf16idx()` for getting the character and UTF-16 index respectively from the byte index.

Examples:

```
echo byteidx('a\u0304', 2) returns 5
echo byteidx('a\u0304', 2, 1) returns 1
echo byteidx('a\u0304', 3, 1) returns 5
```

Can also be used as a `method` :

```
GetName()->byteidx(idx)
```

Return type: `Number`

`byteidxcomp({expr}, {nr} [, {utf16}])` `byteidxcomp()`

Like `byteidx()`, except that a composing character is counted as a separate character. Example:

```
let s = 'e' .. nr2char(0x301)
echo byteidx(s, 1)
echo byteidxcomp(s, 1)
echo byteidxcomp(s, 2)
```

The first and third echo result in 3 ('e' plus composing character is 3 bytes), the second echo results in 1 ('e' is one byte).  
Only works differently from `byteidx()` when **'encoding'** is set to a Unicode encoding.

Can also be used as a **method** :  
`GetName()->byteidxcomp(idx)`

Return type: **Number**

`call({func}, {arglist} [, {dict}])` **call()** E699  
Call function `{func}` with the items in **List** `{arglist}` as arguments.  
`{func}` can either be a **Funcref** or the name of a function.  
`a:firstline` and `a:lastline` are set to the cursor line.  
Returns the return value of the called function.  
`{dict}` is for functions with the "dict" attribute. It will be used to set the local variable "self". **Dictionary-function**

Can also be used as a **method** :  
`GetFunc()->call([arg, arg], dict)`

Return type: any, depending on `{func}`

`ceil({expr})` **ceil()**  
Return the smallest integral value greater than or equal to `{expr}` as a **Float** (round up).  
`{expr}` must evaluate to a **Float** or a **Number** .  
Examples:

```
echo ceil(1.456)
2.0
echo ceil(-5.456)
-5.0
echo ceil(4.0)
4.0
```

Returns 0.0 if `{expr}` is not a **Float** or a **Number** .

Can also be used as a **method** :  
`Compute()->ceil()`

Return type: **Float**

`ch_` functions are documented here: [channel-functions-details](#)

`changenr()` **changenr()**  
Return the number of the most recent change. This is the same number as what is displayed with `:undolist` and can be used with the `:undo` command.

When a change was made it is the number of that change. After redo it is the number of the redone change. After undo it is one less than the number of the undone change. Returns 0 if the undo list is empty.

Return type: `Number`

`char2nr({string} [, {utf8}])` `char2nr()`

Return Number value of the first char in `{string}`.

Examples:

```
char2nr(" ") returns 32
char2nr("ABC") returns 65
```

When `{utf8}` is omitted or zero, the current `'encoding'` is used.

Example for "utf-8":

```
char2nr("á") returns 225
char2nr("á"[0]) returns 195
```

When `{utf8}` is TRUE, always treat as UTF-8 characters.

A combining character is a separate character.

`nr2char()` does the opposite.

To turn a string into a list of character numbers:

```
let str = "ABC"
let list = map(split(str, '\zs'), {_, val -> char2nr(val)})
```

Result: [65, 66, 67]

Returns 0 if `{string}` is not a `String` .

Can also be used as a `method` :

```
GetChar()->char2nr()
```

Return type: `Number`

`charclass({string})` `charclass()`

Return the character class of the first character in `{string}`.

The character class is one of:

```
0 blank
1 punctuation
2 word character (depends on 'iskeyword')
3 emoji
other specific Unicode class
```

The class is used in patterns and word motions.

Returns 0 if `{string}` is not a `String` .

Return type: `Number`

`charcol({expr} [, {winid}])` `charcol()`

Same as `col()` but returns the character index of the column position given with `{expr}` instead of the byte position.

Example:

With the cursor on 'x' in line 5 with text "xxxxx":

```
charcol('.') returns 3
```

`col('.')` returns 7

Can also be used as a `method` :  
`GetPos()->col()`

Return type: `Number`

`charidx({string}, {idx} [, {countcc} [, {utf16}]])` `charidx()`  
Return the character index of the byte at `{idx}` in `{string}`.  
The index of the first character is zero.  
If there are no multibyte characters the returned value is equal to `{idx}`.

When `{countcc}` is omitted or `FALSE` , then composing characters are not counted separately, their byte length is added to the preceding base character.

When `{countcc}` is `TRUE` , then composing characters are counted as separate characters.

When `{utf16}` is present and `TRUE`, `{idx}` is used as the UTF-16 index in the String `{expr}` instead of as the byte index.

Returns -1 if the arguments are invalid or if there are less than `{idx}` bytes. If there are exactly `{idx}` bytes the length of the string in characters is returned.

An error is given and -1 is returned if the first argument is not a string, the second argument is not a number or when the third argument is present and is not zero or one.

See `byteidx()` and `byteidxcomp()` for getting the byte index from the character index and `utf16idx()` for getting the UTF-16 index from the character index.

Refer to [string-offset-encoding](#) for more information.

Examples:

```
echo charidx('ábc', 3) returns 1
echo charidx('ábc', 6, 1) returns 4
echo charidx('ábc', 16) returns -1
echo charidx('a\xff', 4, 0, 1) returns 2
```

Can also be used as a `method` :  
`GetName()->charidx(idx)`

Return type: `Number`

`chdir({dir})` `chdir()`

Change the current working directory to `{dir}`. The scope of the directory change depends on the directory of the current window:

- If the current window has a window-local directory (`:lcd`), then changes the window local directory.
- Otherwise, if the current tabpage has a local

directory ( :tcd ) then changes the tabpage local directory.  
- Otherwise, changes the global directory.  
{dir} must be a String.  
If successful, returns the previous working directory. Pass this to another chdir() to restore the directory.  
On failure, returns an empty string.

Example:

```
let save_dir = chdir(newdir)
if save_dir != ""
 ... do some work
 call chdir(save_dir)
endif
```

Can also be used as a method :  
GetDir()->chdir()

Return type: String

cindent({lnum})

cindent()

Get the amount of indent for line {lnum} according the C indenting rules, as with 'cindent'.  
The indent is counted in spaces, the value of 'tabstop' is relevant. {lnum} is used just like in getline().  
When {lnum} is invalid -1 is returned.  
See C-indenting .

Can also be used as a method :  
GetLnum()->cindent()

Return type: Number

clearmatches([{win}])

clearmatches()

Clears all matches previously defined for the current window by matchadd() and the :match commands.  
If {win} is specified, use the window with this number or window ID instead of the current window.

Can also be used as a method :  
GetWin()->clearmatches()

Return type: Number

col({expr} [, {winid}])

col()

The result is a Number, which is the byte index of the column position given with {expr}.  
For accepted positions see getpos().  
When {expr} is "\$", it means the end of the cursor line, so the result is the number of bytes in the cursor line plus one.  
Additionally {expr} can be [lnum, col]: a List with the line

and column number. Most useful when the column is "\$", to get the last column of a specific line. When "lnum" or "col" is out of range then col() returns zero.

With the optional {winid} argument the values are obtained for that window instead of the current window.

To get the line number use line() . To get both use getpos() .

For the screen column position use virtcol() . For the character position use charcol() .

Note that only marks in the current file can be used.

Examples:

col(".")	column of cursor
col("\$")	length of cursor line plus one
col("'t")	column of mark t
col("' " .. markname)	column of mark markname

The first column is 1. Returns 0 if {expr} is invalid or when the window with ID {winid} is not found.

For an uppercase mark the column may actually be in another buffer.

For the cursor position, when 'virtualedit' is active, the column is one higher if the cursor is after the end of the line. Also, when using a <Cmd> mapping the cursor isn't moved, this can be used to obtain the column in Insert mode:

```
:imap <F2> <Cmd>echowin col(".")<CR>
```

Can also be used as a method :

```
GetPos()->col()
```

Return type: Number

complete({startcol}, {matches}) complete() E785

Set the matches for Insert mode completion.

Can only be used in Insert mode. You need to use a mapping with CTRL-R = (see i\_CTRL-R ). It does not work after CTRL-O or with an expression mapping.

{startcol} is the byte offset in the line where the completed text start. The text up to the cursor is the original text that will be replaced by the matches. Use col('.') for an empty string. "col('.') - 1" will replace one character by a match.

{matches} must be a List . Each List item is one match. See complete-items for the kind of items that are possible. "longest" in 'completeopt' is ignored.

Note that the after calling this function you need to avoid inserting anything that would cause completion to stop.

The match can be selected with CTRL-N and CTRL-P as usual with Insert mode completion. The popup menu will appear if specified, see ins-completion-menu .

Example:  
`inoremap <F5> <C-R>=ListMonths(<CR>`

```
func ListMonths()
 call complete(col('.'), ['January', 'February', 'March',
 \ 'April', 'May', 'June', 'July', 'August', 'September',
 \ 'October', 'November', 'December'])
 return ''
endfunc
```

This isn't very useful, but it shows how it works. [Note](#) that an empty string is returned to avoid a zero being inserted.

Can also be used as a [method](#) , the base is passed as the second argument:

```
GetMatches()->complete(col('.'))
```

Return type: [Number](#)

`complete_add({expr})`

[complete\\_add\(\)](#)

Add `{expr}` to the list of matches. Only to be used by the function specified with the `'completefunc'` option. Returns 0 for failure (empty string or out of memory), 1 when the match was added, 2 when the match was already in the list.

See [complete-functions](#) for an explanation of `{expr}`. It is the same as one item in the list that `'omnifunc'` would return.

Can also be used as a [method](#) :

```
GetMoreMatches()->complete_add()
```

Return type: [Number](#)

`complete_check()`

[complete\\_check\(\)](#)

Check for a key typed while looking for completion matches. This is to be used when looking for matches takes some time. Returns `TRUE` when searching for matches is to be aborted, zero otherwise.

Only to be used by the function specified with the `'completefunc'` option.

Return type: [Number](#)

`complete_info([{what}])`

[complete\\_info\(\)](#)

Returns a [Dictionary](#) with information about Insert mode completion. See [ins-completion](#) .

The items are:

<code>mode</code>	Current completion mode name string. See <a href="#">complete_info_mode</a> for the values.
<code>pum_visible</code>	<code>TRUE</code> if popup menu is visible. See <a href="#">pumvisible()</a> .
<code>items</code>	List of all completion candidates. Each item

is a dictionary containing the entries "word", "abbr", "menu", "kind", "info" and "user\_data". See [complete-items](#) .

matches Same as "items", but only returns items that are matching current query. If both "matches" and "items" are in "what", the returned list will still be named "items", but each item will have an additional "match" field.

selected Selected item index. First index is zero. Index is -1 if no item is selected (showing typed text only, or the last completion after no item is selected when using the <Up> or <Down> keys)

completed Return a dictionary containing the entries of the currently selected index item.

### complete\_info\_mode

mode values are:

```

"" Not in completion mode
"keyword" Keyword completion i_CTRL-X_CTRL-N
"ctrl_x" Just pressed CTRL-X i_CTRL-X
"scroll" Scrolling with i_CTRL-X_CTRL-E or
 i_CTRL-X_CTRL-Y
"whole_line" Whole lines i_CTRL-X_CTRL-L
"files" File names i_CTRL-X_CTRL-F
"tags" Tags i_CTRL-X_CTRL-]
"path_defines" Definition completion i_CTRL-X_CTRL-D
"path_patterns" Include completion i_CTRL-X_CTRL-I
"dictionary" Dictionary i_CTRL-X_CTRL-K
"thesaurus" Thesaurus i_CTRL-X_CTRL-T
"cmdline" Vim Command line i_CTRL-X_CTRL-V
"function" User defined completion i_CTRL-X_CTRL-U
"omni" Omni completion i_CTRL-X_CTRL-O
"spell" Spelling suggestions i_CTRL-X_s
"eval" complete() completion
"unknown" Other internal modes

```

If the optional `{what}` list argument is supplied, then only the items listed in `{what}` are returned. Unsupported items in `{what}` are silently ignored.

To get the position and size of the popup menu, see [pum\\_getpos\(\)](#) . It's also available in `v:event` during the `CompleteChanged` event.

Returns an empty `Dictionary` on error.

Examples:

```

" Get all items
call complete_info()
" Get only 'mode'
call complete_info(['mode'])
" Get only 'mode' and 'pum_visible'
call complete_info(['mode', 'pum_visible'])

```

Can also be used as a `method` :  
`GetItems()->complete_info()`

Return type: `dict<any>`

```
confirm({msg} [, {choices} [, {default} [, {type}]]])
```

`confirm()` offers the user a dialog, from which a choice can be made. It returns the number of the choice. For the first choice this is 1.  
**Note:** `confirm()` is only supported when compiled with dialog support, see `+dialog_con` `+dialog_con_gui` and `+dialog_gui` .

`{msg}` is displayed in a `dialog` with `{choices}` as the alternatives. When `{choices}` is missing or empty, "&OK" is used (and translated).

`{msg}` is a String, use '\n' to include a newline. Only on some systems the string is wrapped when it doesn't fit.

`{choices}` is a String, with the individual choices separated by '\n', e.g.

```
confirm("Save changes?", "&Yes\n&No\n&Cancel")
```

The letter after the '&' is the shortcut key for that choice. Thus you can type 'c' to select "Cancel". The shortcut does not need to be the first letter:

```
confirm("file has been modified", "&Save\nSave &All")
```

For the console, the first letter of each choice is used as the default shortcut key. Case is ignored.

The optional `{default}` argument is the number of the choice that is made if the user hits <CR>. Use 1 to make the first choice the default one. Use 0 to not set a default. If `{default}` is omitted, 1 is used.

The optional `{type}` String argument gives the type of dialog. This is only used for the icon of the GTK, Mac, Motif and Win32 GUI. It can be one of these values: "Error", "Question", "Info", "Warning" or "Generic". Only the first character is relevant. When `{type}` is omitted, "Generic" is used.

If the user aborts the dialog by pressing <Esc>, **CTRL-C**, or another valid interrupt key, `confirm()` returns 0.

An example:

```
let choice = confirm("What do you want?",
 \ "&Apples\n&Oranges\n&Bananas", 2)
if choice == 0
 echo "make up your mind!"
elseif choice == 3
 echo "tasteful"
else
 echo "I prefer bananas myself."
```

endif

In a GUI dialog, buttons are used. The layout of the buttons depends on the 'v' flag in 'guioptions'. If it is included, the buttons are always put vertically. Otherwise, confirm() tries to put the buttons in one horizontal line. If they don't fit, a vertical layout is used anyway. For some systems the horizontal layout is always used.

Can also be used as a method in:

```
BuildMessage()->confirm("&Yes\n&No")
```

Return type: Number

copy({expr})

copy()

Make a copy of {expr}. For Numbers and Strings this isn't different from using {expr} directly.

When {expr} is a List a shallow copy is created. This means that the original List can be changed without changing the copy, and vice versa. But the items are identical, thus changing an item changes the contents of both Lists.

A Dictionary is copied in a similar way as a List.

Also see deepcopy().

Can also be used as a method :

```
mylist->copy()
```

Return type: any, depending on {expr}

cos({expr})

cos()

Return the cosine of {expr}, measured in radians, as a Float. {expr} must evaluate to a Float or a Number.

Returns 0.0 if {expr} is not a Float or a Number.

Examples:

```
:echo cos(100)
0.862319
:echo cos(-4.01)
-0.646043
```

Can also be used as a method :

```
Compute()->cos()
```

Return type: Float

cosh({expr})

cosh()

Return the hyperbolic cosine of {expr} as a Float in the range [1, inf].

{expr} must evaluate to a Float or a Number.

Returns 0.0 if {expr} is not a Float or a Number.

Examples:

```
:echo cosh(0.5)
1.127626
:echo cosh(-0.5)
```

-1.127626

Can also be used as a `method` :  
`Compute()->cosh()`

Return type: `Float`

`count({comp}, {expr} [, {ic} [, {start}]]])` `count()` E706

Return the number of times an item with value `{expr}` appears in `String`, `List` or `Dictionary` `{comp}`.

If `{start}` is given then start with the item with this index. `{start}` can only be used with a `List`.

When `{ic}` is given and it's `TRUE` then case is ignored.

When `{comp}` is a string then the number of not overlapping occurrences of `{expr}` is returned. Zero is returned when `{expr}` is an empty string.

Can also be used as a `method` :  
`mylist->count(val)`

Return type: `Number`

`cscope_connection([num] , {dbpath} [, {prepend}])` `cscope_connection()`

Checks for the existence of a `cscope` connection. If no parameters are specified, then the function returns:  
0, if `cscope` was not available (not compiled in), or if there are no `cscope` connections;  
1, if there is at least one `cscope` connection.

If parameters are specified, then the value of `{num}` determines how existence of a `cscope` connection is checked:

<code>{num}</code>	Description of existence check
0	Same as no parameters (e.g., "cscope_connection").
1	Ignore <code>{prepend}</code> , and use partial string matches for <code>{dbpath}</code> .
2	Ignore <code>{prepend}</code> , and use exact string matches for <code>{dbpath}</code> .
3	Use <code>{prepend}</code> , use partial string matches for both <code>{dbpath}</code> and <code>{prepend}</code> .
4	Use <code>{prepend}</code> , use exact string matches for both <code>{dbpath}</code> and <code>{prepend}</code> .

**Note:** All string comparisons are case sensitive!

Examples. Suppose we had the following (from "cs show"):

```
pid database name prepend path
```

Invocation	Return Val
cscope_connection()	1
cscope_connection(1, "out")	1
cscope_connection(2, "out")	0
cscope_connection(3, "out")	0
cscope_connection(3, "out", "local")	1
cscope_connection(4, "out")	0
cscope_connection(4, "out", "local")	0
cscope_connection(4, "cscope.out", "/usr/local")	1

Return type: **Number**

cursor({lnum}, {col} [, {off}])  
 cursor({list})

**cursor()**

Positions the cursor at the column (byte count) {col} in the line {lnum}. The first column is one.

When there is one argument {list} this is used as a **List** with two, three or four item:

```
[{lnum}, {col}]
[{lnum}, {col}, {off}]
[{lnum}, {col}, {off}, {curswant}]
```

This is like the return value of **getpos()** or **getcurpos()** , but without the first item.

To position the cursor using {col} as the character count, use **setcursorcharpos()** .

Does not change the jumplist.

{lnum} is used like with **getline()** , except that if {lnum} is zero, the cursor will stay in the current line.

If {lnum} is greater than the number of lines in the buffer, the cursor will be positioned at the last line in the buffer.

If {col} is greater than the number of bytes in the line, the cursor will be positioned at the last character in the line.

If {col} is zero, the cursor will stay in the current column.

If {curswant} is given it is used to set the preferred column for vertical movement. Otherwise {col} is used.

When '**virtualedit**' is used {off} specifies the offset in screen columns from the start of the character. E.g., a position within a **<Tab>** or after the last character.

Returns 0 when the position could be set, -1 otherwise.

Can also be used as a **method** :

```
GetCursorPos()->cursor()
```

Return type: **Number**

`debugbreak({pid})` `debugbreak()`  
Specifically used to interrupt a program being debugged. It will cause process `{pid}` to get a SIGTRAP. Behavior for other processes is undefined. See [terminal-debugger](#) .  
`{only available on MS-Windows}`

Returns `TRUE` if successfully interrupted the program. Otherwise returns `FALSE` .

Can also be used as a `method` :  
`GetPid()->debugbreak()`

Return type: `Number`

`deepcopy({expr} [, {noref}])` `deepcopy()` E698  
Make a copy of `{expr}`. For Numbers and Strings this isn't different from using `{expr}` directly.  
When `{expr}` is a `List` a full copy is created. This means that the original `List` can be changed without changing the copy, and vice versa. When an item is a `List` or `Dictionary` , a copy for it is made, recursively. Thus changing an item in the copy does not change the contents of the original `List` .  
A `Dictionary` is copied in a similar way as a `List` .

When `{noref}` is omitted or zero a contained `List` or `Dictionary` is only copied once. All references point to this single copy. With `{noref}` set to 1 every occurrence of a `List` or `Dictionary` results in a new copy. This also means that a cyclic reference causes `deepcopy()` to fail.

E724

Nesting is possible up to 100 levels. When there is an item that refers back to a higher level making a deep copy with `{noref}` set to 1 will fail.  
Also see `copy()` .

Can also be used as a `method` :  
`GetObject()->deepcopy()`

Return type: any, depending on `{expr}`

`delete({fname} [, {flags}])` `delete()`  
Without `{flags}` or with `{flags}` empty: Deletes the file by the name `{fname}`.  
  
This also works when `{fname}` is a symbolic link. The symbolic link itself is deleted, not what it points to.  
  
When `{flags}` is "d": Deletes the directory by the name `{fname}`. This fails when directory `{fname}` is not empty.

When `{flags}` is "rf": Deletes the directory by the name `{fname}` and everything in it, recursively. BE CAREFUL!  
**Note:** on MS-Windows it is not possible to delete a directory that is being used.

The result is a Number, which is 0/false if the delete operation was successful and -1/true when the deletion failed or partly failed.

Use `remove()` to delete an item from a `List` .  
To delete a line from the buffer use `:delete` or `deletebufline()` .

Can also be used as a `method` :  
`GetName()->delete()`

Return type: `Number`

`deletebufline({buf}, {first} [, {last}])` `deletebufline()`  
Delete lines `{first}` to `{last}` (inclusive) from buffer `{buf}`.  
If `{last}` is omitted then delete line `{first}` only.  
On success 0 is returned, on failure 1 is returned.

This function works only for loaded buffers. First call `bufload()` if needed.

For the use of `{buf}`, see `bufname()` above.

`{first}` and `{last}` are used like with `getline()` . **Note** that when using `line()` this refers to the current buffer. Use "\$" to refer to the last line in buffer `{buf}`.

Can also be used as a `method` :  
`GetBuffer()->deletebufline(1)`

Return type: `Number`

`did_filetype()` `did_filetype()`  
Returns `TRUE` when autocommands are being executed and the FileType event has been triggered at least once. Can be used to avoid triggering the FileType event again in the scripts that detect the file type. `FileType`  
Returns `FALSE` when ``:setf FALLBACK`` was used.  
When editing another file, the counter is reset, thus this really checks if the FileType event has been triggered for the current buffer. This allows an autocommand that starts editing another buffer to set `'filetype'` and load a syntax file.

Return type: `Number`

`diff({fromlist}, {tolist} [, {options}])` `diff()`

Returns a String or a List containing the diff between the strings in `{fromlist}` and `{tolist}`. Uses the Vim internal diff library to compute the diff.

#### E106

The optional "output" item in `{options}` specifies the returned diff format. The following values are supported:

indices	Return a List of the starting and ending indices and a count of the strings in each diff hunk.
unified	Return the unified diff output as a String. This is the default.

If the "output" item in `{options}` is "indices", then a List is returned. Each List item contains a Dict with the following items for each diff hunk:

from_idx	start index in <code>{fromlist}</code> for this diff hunk.
from_count	number of strings in <code>{fromlist}</code> that are added/removed/modified in this diff hunk.
to_idx	start index in <code>{tolist}</code> for this diff hunk.
to_count	number of strings in <code>{tolist}</code> that are added/removed/modified in this diff hunk.

The `{options}` Dict argument also specifies diff options (similar to `'diffopt'`) and supports the following items:

algorithm	Dict specifying the diff algorithm to use. Supported boolean items are "myers", "minimal", "patience" and "histogram".
context	diff context length. Default is 0.
iblack	ignore changes where lines are all blank.
icase	ignore changes in case of text.
indent-heuristic	use the indent heuristic for the internal diff library.
iwhite	ignore changes in amount of white space.
iwhiteall	ignore all white space changes.
iwhiteeol	ignore white space changes at end of line.

For more information about these options, refer to `'diffopt'`.

To compute the unified diff, all the items in `{fromlist}` are concatenated into a string using a newline separator and the same for `{tolist}`. The unified diff output uses line numbers.

Returns an empty List or String if `{fromlist}` and `{tolist}` are identical.

Examples:

```
:echo diff(['abc'], ['xxx'])
@@ -1 +1 @@
-abc
+xxx
```

```

:echo diff(['abc'], ['xxx'], {'output': 'indices'})
[{'from_idx': 0, 'from_count': 1, 'to_idx': 0, 'to_count': 1}]
:echo diff(readfile('oldfile'), readfile('newfile'))
:echo diff(getbufline(5, 1, '$'), getbufline(6, 1, '$'))

```

For more examples, refer to [diff-func-examples](#)

Can also be used as a [method](#) :  
[GetFromList](#)->diff(to\_list)

Return type: [String](#) or list<dict<number>> or list<any>  
depending on [options](#)

diff\_filler({lnum}) [diff\\_filler\(\)](#)

Returns the number of filler lines above line [{lnum}](#).  
These are the lines that were inserted at this point in  
another diff'ed window. These filler lines are shown in the  
display but don't exist in the buffer.  
[{lnum}](#) is used like with [getline\(\)](#). Thus "." is the current  
line, "m" mark m, etc.  
Returns 0 if the current window is not in diff mode.

Can also be used as a [method](#) :  
[GetLnum\(\)](#)->diff\_filler()

Return type: [Number](#)

diff\_hlID({lnum}, {col}) [diff\\_hlID\(\)](#)

Returns the highlight ID for diff mode at line [{lnum}](#) column  
[{col}](#) (byte index). When the current line does not have a  
diff change zero is returned.  
[{lnum}](#) is used like with [getline\(\)](#). Thus "." is the current  
line, "m" mark m, etc.  
[{col}](#) is 1 for the leftmost column, [{lnum}](#) is 1 for the first  
line.  
The highlight ID can be used with [synIDattr\(\)](#) to obtain  
syntax information about the highlighting.

Can also be used as a [method](#) :  
[GetLnum\(\)](#)->diff\_hlID(col)

Return type: [Number](#)

digraph\_get({chars}) [digraph\\_get\(\)](#) [E1214](#)

Return the digraph of [{chars}](#). This should be a string with  
exactly two characters. If [{chars}](#) are not just two  
characters, or the digraph of [{chars}](#) does not exist, an error  
is given and an empty string is returned.

The character will be converted from Unicode to ['encoding'](#)

when needed. This does require the conversion to be available, it might fail.

Also see `digraph_getlist()` .

Examples:

```
" Get a built-in digraph
:echo digraph_get('00') " Returns '∞'

" Get a user-defined digraph
:call digraph_set('aa', '∞')
:echo digraph_get('aa') " Returns '∞'
```

Can also be used as a `method` :  
`GetChars()->digraph_get()`

Return type: `String`

This function works only when compiled with the `+digraphs` feature. If this feature is disabled, this function will display an error message.

`digraph_getlist([listall])` `digraph_getlist()`  
Return a list of digraphs. If the `{listall}` argument is given and it is TRUE, return all digraphs, including the default digraphs. Otherwise, return only user-defined digraphs.

The characters will be converted from Unicode to `'encoding'` when needed. This does require the conservation to be available, it might fail.

Also see `digraph_get()` .

Examples:

```
" Get user-defined digraphs
:echo digraph_getlist()

" Get all the digraphs, including default digraphs
:echo digraph_getlist(1)
```

Can also be used as a `method` :  
`GetNumber()->digraph_getlist()`

Return type: `list<list<string>>`

This function works only when compiled with the `+digraphs` feature. If this feature is disabled, this function will display an error message.

`digraph_set({chars}, {digraph})` `digraph_set()`  
Add digraph `{chars}` to the list. `{chars}` must be a string with two characters. `{digraph}` is a string with one UTF-8

encoded character. [E1215](#)

Be careful, composing characters are NOT ignored. This function is similar to `:digraphs` command, but useful to add digraphs start with a white space.

The function returns `v:true` if `digraph` is registered. If this fails an error message is given and `v:false` is returned.

If you want to define multiple digraphs at once, you can use `digraph_setlist()` .

Example:

```
call digraph_set(' ', '␣')
```

Can be used as a `method` :

```
GetString()->digraph_set('␣')
```

Return type: `vim9-boolean`

This function works only when compiled with the `+digraphs` feature. If this feature is disabled, this function will display an error message.

`digraph_setlist({digraphlist})` [digraph\\_setlist\(\)](#)

Similar to `digraph_set()` but this function can add multiple digraphs at once. `{digraphlist}` is a list composed of lists, where each list contains two strings with `{chars}` and `{digraph}` as in `digraph_set()` . [E1216](#)

Example:

```
call digraph_setlist(['aa', '␣'], ['ii', '␣'])
```

It is similar to the following:

```
for [chars, digraph] in [['aa', '␣'], ['ii', '␣']]
 call digraph_set(chars, digraph)
endfor
```

Except that the function returns after the first error, following digraphs will not be added.

Can be used as a `method` :

```
GetList()->digraph_setlist()
```

Return type: `vim9-boolean`

This function works only when compiled with the `+digraphs` feature. If this feature is disabled, this function will display an error message.

`echoraw({string})` [echoraw\(\)](#)

Output `{string}` as-is, including unprintable characters. This can be used to output a terminal code. For example, to disable `modifyOtherKeys`:

```
call echoraw(&t_TE)
```

and to enable it again:

```
call echoraw(&t_TI)
```

Use with care, you can mess up the terminal this way.

Return type: `Number`

`empty({expr})`

`empty()`

Return the `Number` 1 if `{expr}` is empty, zero otherwise.

- A `List` or `Dictionary` is empty when it does not have any items.
- A `String` is empty when its length is zero.
- A `Number` and `Float` are empty when their value is zero.
- `v:false`, `v:none` and `v:null` are empty, `v:true` is not.
- A `Job` is empty when it failed to start.
- A `Channel` is empty when it is closed.
- A `Blob` is empty when its length is zero.
- An `Object` is empty, when the `empty()` method in the object (if present) returns true. `object-empty()`

For a long `List` this is much faster than comparing the length with zero.

Can also be used as a `method` :

```
mylist->empty()
```

Return type: `Number`

`environ()`

`environ()`

Return all of environment variables as dictionary. You can check if an environment variable exists like this:

```
:echo has_key(environ(), 'HOME')
```

**Note** that the variable name may be CamelCase; to ignore case use this:

```
:echo index(keys(environ()), 'HOME', 0, 1) != -1
```

Return type: `dict<string>`

`err_teapot([{expr}])`

`err_teapot()`

Produce an error with number 418, needed for implementation of RFC 2324.

If `{expr}` is present and it is TRUE error 503 is given, indicating that coffee is temporarily not available.

If `{expr}` is present it must be a `String`.

Return type: `Number`

`escape({string}, {chars})`

`escape()`

Escape the characters in `{chars}` that occur in `{string}` with a backslash. Example:

```
:echo escape('c:\program files\vim', ' \')
```

results in:

`c:\\program\ files\\vim`

Also see `shellescape()` and `fnameescape()` .

Can also be used as a `method` :

`GetText()->escape(' \')`

Return type: `String`

`eval({string})` `eval()`  
Evaluate `{string}` and return the result. Especially useful to turn the result of `string()` back into the original value. This works for Numbers, Floats, Strings, Blobs and composites of them. Also works for `Funcref` s that refer to existing functions. In `Vim9` script, it can be used to obtain `enum` values from their fully qualified names.

Can also be used as a `method` :

`argv->join()->eval()`

Return type: any, depending on `{string}`

`eventhandler()` `eventhandler()`  
Returns 1 when inside an event handler. That is that Vim got interrupted while waiting for the user to type a character, e.g., when dropping a file on Vim. This means interactive commands cannot be used. Otherwise zero is returned.

Return type: `Number`

`executable({expr})` `executable()`  
This function checks if an executable with the name `{expr}` exists. `{expr}` must be the name of the program without any arguments.

`executable()` uses the value of `$PATH` and/or the normal searchpath for programs.

#### `PATHEXT`

On MS-Windows the ".exe", ".bat", etc. can optionally be included. Then the extensions in `$PATHEXT` are tried. Thus if "foo.exe" does not exist, "foo.exe.bat" can be found. If `$PATHEXT` is not set then ".com;.exe;.bat;.cmd" is used. A dot by itself can be used in `$PATHEXT` to try using the name without an extension. When '`shell`' looks like a Unix shell, then the name is also tried without adding an extension.

On MS-Windows it only checks if the file exists and is not a directory, not if it's really executable.

On MS-Windows an executable in the same directory as the Vim executable is always found. Since this directory is added to `$PATH` it should also work to execute it `win32-PATH` .

#### `NoDefaultCurrentDirectoryInExePath`

On MS-Windows an executable in Vim's current working directory

is also normally found, but this can be disabled by setting the \$NoDefaultCurrentDirectoryInExePath environment variable.

The result is a Number:

```
1 exists
0 does not exist
-1 not implemented on this system
```

`exepath()` can be used to get the full path of an executable.

Can also be used as a `method` :

```
GetCommand()->executable()
```

Return type: `Number`

`execute({command} [, {silent}])` `execute()`

Execute an Ex command or commands and return the output as a string.

`{command}` can be a string or a List. In case of a List the lines are executed one by one.

This is more or less equivalent to:

```
redir => var
{command}
redir END
```

Except that line continuation in `{command}` is not recognized.

The optional `{silent}` argument can have these values:

```
"" no `:silent` used
"silent" `:silent` used
"silent!" `:silent!` used
```

The default is "silent". **Note** that with "silent!", unlike `:redir`, error messages are dropped. When using an external command the screen may be messed up, use `system()` instead.

**E930**

It is not possible to use `:redir` anywhere in `{command}`.

To get a list of lines use `split()` on the result:

```
execute('args')->split("\n")
```

To execute a command in another window than the current one use `win_execute()`.

When used recursively the output of the recursive call is not included in the output of the higher level call.

Can also be used as a `method` :

```
GetCommand()->execute()
```

Return type: `String`

`exepath({expr})` `exepath()`

If `{expr}` is an executable and is either an absolute path, a relative path or found in \$PATH, return the full path.

**Note** that the current directory is used when `{expr}` starts with `"/"`, which may be a problem for Vim:

```
echo exepath(v:progbath)
```

If `{expr}` cannot be found in `$PATH` or is not executable then an empty string is returned.

Can also be used as a **method** :

```
GetCommand()->exepath()
```

Return type: **String**

`exists({expr})`

**exists()**

The result is a Number, which is **TRUE** if `{expr}` is defined, zero otherwise.

**Note:** In a compiled `:def` function the evaluation is done at runtime. Use ``exists_compiled()`` to evaluate the expression at compile time.

For checking for a supported feature use `has()` .

For checking if a file exists use `filereadable()` .

The `{expr}` argument is a string, which contains one of these:

<code>varname</code>	internal variable (see
<code>dict.key</code>	<code>internal-variables</code> ). Also works
<code>list[i]</code>	for <code>curly-braces-names</code> , <code>Dictionary</code>
<code>import.Func</code>	entries, <code>List</code> items, class and
<code>class.Func</code>	object methods, imported items, etc.
<code>object.Func</code>	Does not work for local variables in a
<code>class.varname</code>	compiled <code>:def</code> function.
<code>object.varname</code>	Also works for a function in <code>Vim9</code>
	script, since it can be used as a
	function reference.
	Beware that evaluating an index may
	cause an error message for an invalid
	expression. E.g.:
	<pre>:let l = [1, 2, 3]</pre>
	<pre>:echo exists("l[5]")</pre>
	0
	<pre>:echo exists("l[xx]")</pre>
	E121: Undefined variable: xx
	0
<code>&amp;option-name</code>	Vim option (only checks if it exists,
	not if it really works)
<code>+option-name</code>	Vim option that works.
<code>\$ENVNAME</code>	environment variable (could also be
	done by comparing with an empty
	string)
<code>*funcname</code>	built-in function (see <code>functions</code> )
	or user defined function (see
	<code>user-functions</code> ) that is implemented.
	Also works for a variable that is a
	Funcref.

?funcname	built-in function that could be implemented; to be used to check if "funcname" is valid
:cmdname	Ex command: built-in command, user command or command modifier <code>:command</code> . Returns: 1 for match with start of a command 2 full match with a command 3 matches several user commands To check for a supported command always check the return value to be 2.
:2match	The <code>:2match</code> command.
:3match	The <code>:3match</code> command (but you probably should not use it, it is reserved for internal usage)
#event	autocommand defined for this event
#event#pattern	autocommand defined for this event and pattern (the pattern is taken literally and compared to the autocommand patterns character by character)
#group	autocommand group exists
#group#event	autocommand defined for this group and event.
#group#event#pattern	autocommand defined for this group, event and pattern.
##event	autocommand for this event is supported.

#### Examples:

```
exists("&shortname")
exists("$HOSTNAME")
exists("*strftime")
exists("s:MyFunc") " only for legacy script
exists("*MyFunc")
exists("bufcount")
exists(":Make")
exists("#CursorHold")
exists("#BufReadPre*.gz")
exists("#filetypeindent")
exists("#filetypeindent#FileType")
exists("#filetypeindent#FileType#*")
exists("##ColorScheme")
```

There must be no space between the symbol (&/\$/\*/#) and the name.

There must be no extra characters after the name, although in a few cases this is ignored. That may become stricter in the future, thus don't count on it!

Working example:

```
exists(":make")
```

NOT working example:

```
exists(":make install")
```

**Note** that the argument must be a string, not the name of the variable itself. For example:

```
exists(bufcount)
```

This doesn't check for existence of the "bufcount" variable, but gets the value of "bufcount", and checks if that exists.

Can also be used as a **method** :

```
Varname()->exists()
```

Return type: **String**

exists\_compiled({expr}) **exists\_compiled()**

Like `exists()` but evaluated at compile time. This is useful to skip a block where a function is used that would otherwise give an error:

```
if exists_compiled('*ThatFunction')
 ThatFunction('works')
endif
```

If `exists()` were used then a compilation error would be given if `ThatFunction()` is not defined.

`{expr}` must be a literal string. **E1232**

Can only be used in a `:def` function. **E1233**

This does not work to check for arguments or local variables.

Return type: **String**

exp({expr}) **exp()**

Return the exponential of `{expr}` as a **Float** in the range `[0, inf]`.

`{expr}` must evaluate to a **Float** or a **Number**.

Returns 0.0 if `{expr}` is not a **Float** or a **Number**.

Examples:

```
:echo exp(2)
7.389056
:echo exp(-1)
0.367879
```

Can also be used as a **method** :

```
Compute()->exp()
```

Return type: **Float**

expand({string} [, {nosuf} [, {list}]]) **expand()**

Expand wildcards and the following special keywords in `{string}`. **'wildignorecase'** applies.

If `{list}` is given and it is **TRUE**, a List will be returned. Otherwise the result is a String and when there are several matches, they are separated by `<NL>` characters. [Note: in version 5.0 a space was used, which caused problems when a

file name contains a space]

If the expansion fails, the result is an empty string. A name for a non-existing file is not included, unless `{string}` does not start with '%', '#' or '<', see below.

For a `:terminal` window '%' expands to a '!' followed by the command or shell that is run. `terminal-bufname`

When `{string}` starts with '%', '#' or '<', the expansion is done like for the `cmdline-special` variables with their associated modifiers. Here is a short overview:

<code>%</code>	current file name
<code>#</code>	alternate file name
<code>#n</code>	alternate file name n
<code>&lt;cfile&gt;</code>	file name under the cursor
<code>&lt;afile&gt;</code>	autocmd file name
<code>&lt;abuf&gt;</code>	autocmd buffer number (as a String!)
<code>&lt;amatch&gt;</code>	autocmd matched name
<code>&lt;cexpr&gt;</code>	C expression under the cursor
<code>&lt;sfile&gt;</code>	sourced script file or function name
<code>&lt;slnum&gt;</code>	sourced script line number or function line number
<code>&lt;sflnum&gt;</code>	script file line number, also when in a function
<code>&lt;SID&gt;</code>	"<SNR>123_" where "123" is the current script ID <code>&lt;SID&gt;</code>
<code>&lt;script&gt;</code>	sourced script file, or script file where the current function was defined
<code>&lt;stack&gt;</code>	call stack
<code>&lt;word&gt;</code>	word under the cursor
<code>&lt;cWORD&gt;</code>	WORD under the cursor
<code>&lt;client&gt;</code>	the <code>{clientid}</code> of the last received message <code>server2client()</code>

Modifiers:

<code>:p</code>	expand to full path
<code>:h</code>	head (last path component removed)
<code>:t</code>	tail (last path component only)
<code>:r</code>	root (one extension removed)
<code>:e</code>	extension only

Example:

```
:let &tags = expand("%:p:h") .. "/tags"
```

**Note** that when expanding a string that starts with '%', '#' or '<', any following text is ignored. This does NOT work:

```
:let doesntwork = expand("%:h.bak")
```

Use this:

```
:let doeswork = expand("%:h") .. ".bak"
```

Also **note** that expanding "`<cfile>`" and others only returns the referenced file name without further expansion. If "`<cfile>`" is "`~/ .cshrc`", you need to do another `expand()` to have the "`~/`" expanded into the path of the home directory:

```
:echo expand(expand("<cfile>"))
```

There cannot be white space between the variables and the following modifier. The `fnamemodify()` function can be used to modify normal file names.

When using '%' or '#', and the current or alternate file name is not defined, an empty string is used. Using "%:p" in a buffer with no name, results in the current directory, with a '/' added.

When **'verbose'** is set then expanding '%', '#' and '<>' items will result in an error message if the argument cannot be expanded.

When `{string}` does not start with '%', '#' or '<', it is expanded like a file name is expanded on the command line. **'suffixes'** and **'wildignore'** are used, unless the optional `{nosuf}` argument is given and it is `TRUE`.

Names for non-existing files are included. The "\*" item can be used to search in a directory tree. For example, to find all "README" files in the current directory and below:

```
:echo expand("**/README")
```

`expand()` can also be used to expand variables and environment variables that are only known in a shell. But this can be slow, because a shell may be used to do the expansion. See `expr-env-expand`.

The expanded variable is still handled like a list of file names. When an environment variable cannot be expanded, it is left unchanged. Thus `:echo expand('$FOOBAR')` results in `"$FOOBAR"`.

See `glob()` for finding existing files. See `system()` for getting the raw output of an external command.

Can also be used as a `method` :  
`Getpattern()->expand()`

Return type: `String` or `list<string>` depending on `{list}`

```
expandcmd({string} [, {options}]) expandcmd()
Expand special items in String {string} like what is done for an Ex command such as :edit. This expands special keywords, like with expand(), and environment variables, anywhere in {string}. "~user" and "~/path" are only expanded at the start.
```

The following items are supported in the `{options}` Dict argument:

<code>errmsg</code>	If set to <code>TRUE</code> , error messages are displayed if an error is encountered during expansion. By default, error messages are not displayed.
---------------------	-------------------------------------------------------------------------------------------------------------------------------------------------------

Returns the expanded string. If an error is encountered

during expansion, the unmodified `{string}` is returned.

Example:

```
:echo expandcmd('make %<.o')
make /path/runtime/doc/builtin.o
:echo expandcmd('make %<.o', {'errmsg': v:true})
```

Can also be used as a `method` :

```
GetCommand()->expandcmd()
```

Return type: `String` or `list<string>` depending on `{list}`

```
extend({expr1}, {expr2} [, {expr3}]) extend()
{expr1} and {expr2} must be both Lists or both
Dictionaries .
```

If they are `Lists` : Append `{expr2}` to `{expr1}`.

If `{expr3}` is given insert the items of `{expr2}` before the item with index `{expr3}` in `{expr1}`. When `{expr3}` is zero insert before the first item. When `{expr3}` is equal to `len({expr1})` then `{expr2}` is appended.

Examples:

```
:echo sort(extend(mylist, [7, 5]))
:call extend(mylist, [2, 3], 1)
```

When `{expr1}` is the same List as `{expr2}` then the number of items copied is equal to the original length of the List. E.g., when `{expr3}` is 1 you get N new copies of the first item (where N is the original length of the List).

Use `add()` to concatenate one item to a list. To concatenate two lists into a new list use the `+` operator:

```
:let newlist = [1, 2, 3] + [4, 5]
```

If they are `Dictionaries` :

Add all entries from `{expr2}` to `{expr1}`.

If a key exists in both `{expr1}` and `{expr2}` then `{expr3}` is used to decide what to do:

```
{expr3} = "keep": keep the value of {expr1}
```

```
{expr3} = "force": use the value of {expr2}
```

```
{expr3} = "error": give an error message
```

E737

When `{expr3}` is omitted then "force" is assumed.

`{expr1}` is changed when `{expr2}` is not empty. If necessary make a copy of `{expr1}` first or use `extendnew()` to return a new List/Dictionary.

`{expr2}` remains unchanged.

When `{expr1}` is locked and `{expr2}` is not empty the operation fails.

Returns `{expr1}`. Returns 0 on error.

Can also be used as a `method` :

```
mylist->extend(otherlist)
```

Return type: `list<{type}>` or `dict<{type}>` depending on `{expr1}` and `{expr2}`, in case of error: `Number`

`extendnew({expr1}, {expr2} [, {expr3}])` `extendnew()`  
 Like `extend()` but instead of adding items to `{expr1}` a new List or Dictionary is created and returned. `{expr1}` remains unchanged.

Return type: `list<{type}>` or `dict<{type}>` depending on `{expr1}` and `{expr2}`, in case of error: `Number`

`feedkeys({string} [, {mode}])` `feedkeys()`  
 Characters in `{string}` are queued for processing as if they come from a mapping or were typed by the user.

By default the string is added to the end of the typeahead buffer, thus if a mapping is still being executed the characters come after them. Use the 'i' flag to insert before other characters, they will be executed next, before any characters from a mapping.

The function does not wait for processing of keys contained in `{string}`.

To include special keys into `{string}`, use double-quotes and "\..." notation `expr-quote`. For example, `feedkeys("\<CR>")` simulates pressing of the `<Enter>` key. But `feedkeys('\<CR>')` pushes 5 characters. A special code that might be useful is `<Ignore>`, it exits the wait for a character without doing anything. `<Ignore>`

`{mode}` is a String, which can contain these character flags:

- 'm' Remap keys. This is default. If `{mode}` is absent, keys are remapped.
- 'n' Do not remap keys.
- 't' Handle keys as if typed; otherwise they are handled as if coming from a mapping. This matters for undo, opening folds, etc.
- 'L' Lowlevel input. Only works for Unix or when using the GUI. Keys are used as if they were coming from the terminal. Other flags are not used. **E980**  
 When a **CTRL-C** interrupts and 't' is included it sets the internal "got\_int" flag.
- 'i' Insert the string instead of appending (see above).
- 'x' Execute commands until typeahead is empty. This is similar to using ":normal!". You can call `feedkeys()` several times without 'x' and then one time with 'x' (possibly with an empty `{string}`) to execute all the typeahead. **Note** that when Vim ends in Insert mode it will behave as if `<Esc>` is typed, to avoid getting stuck, waiting for a character to be typed before the script continues.  
**Note** that if you manage to call `feedkeys()` while executing commands, thus calling it recursively, then

all typeahead will be consumed by the last call.  
'c' Remove any script context when executing, so that legacy script syntax applies, "s:var" does not work, etc. **Note** that if the string being fed sets a script context this still applies.  
'!' When used with 'x' will not end Insert mode. Can be used in a test when a timer is set to exit Insert mode a little later. Useful for testing CursorHoldI.

Return value is always 0.

Can also be used as a **method** :  
`GetInput()->feedkeys()`

Return type: **String** or `list<string>` depending on `{list}`

`filecopy({from}, {to})` **filecopy()**  
Copy the file pointed to by the name `{from}` to `{to}`. The result is a Number, which is **TRUE** if the file was copied successfully, and **FALSE** when it failed.  
If a file with name `{to}` already exists, it will fail.  
**Note** that it does not handle directories (yet).

This function is not available in the **sandbox** .

Can also be used as a **method** :  
`GetOldName()->filecopy(newname)`

Return type: **Number**

`filereadable({file})` **filereadable()**  
The result is a Number, which is **TRUE** when a file with the name `{file}` exists, and can be read. If `{file}` doesn't exist, or is a directory, the result is **FALSE** . `{file}` is any expression, which is used as a String.  
If you don't care about the file being readable you can use `glob()` .

`{file}` is used as-is, you may want to expand wildcards first:  
`echo filereadable('~/.vimrc')`  
`0`  
`echo filereadable(expand('~/.vimrc'))`  
`1`

Can also be used as a **method** :  
`GetName()->filereadable()`

Return type: **Number**

Obsolete name: `file_readable()`. **file\_readable()**

filewritable({file})

filewritable()

The result is a Number, which is 1 when a file with the name {file} exists, and can be written. If {file} doesn't exist, or is not writable, the result is 0. If {file} is a directory, and we can write to it, the result is 2.

Can also be used as a method :

```
GetName()->filewritable()
```

Return type: Number

filter({expr1}, {expr2})

filter()

{expr1} must be a List , String , Blob or Dictionary . For each item in {expr1} evaluate {expr2} and when the result is zero or false remove the item from the List or Dictionary . Similarly for each byte in a Blob and each character in a String .

{expr2} must be a string or Funcref .

If {expr2} is a string , inside {expr2} v:val has the value of the current item. For a Dictionary v:key has the key of the current item and for a List v:key has the index of the current item. For a Blob v:key has the index of the current byte. For a String v:key has the index of the current character.

Examples:

```
call filter(mylist, 'v:val !~ "OLD"')
```

Removes the items where "OLD" appears.

```
call filter(mydict, 'v:key >= 8')
```

Removes the items with a key below 8.

```
call filter(var, 0)
```

Removes all the items, thus clears the List or Dictionary .

Note that {expr2} is the result of expression and is then used as an expression again. Often it is good to use a literal-string to avoid having to double backslashes.

If {expr2} is a Funcref it must take two arguments:

1. the key or the index of the current item.
2. the value of the current item.

The function must return TRUE if the item should be kept.

Example that keeps the odd items of a list:

```
func Odd(idx, val)
 return a:idx % 2 == 1
endfunc
```

```
call filter(mylist, function('Odd'))
```

It is shorter when using a lambda . In Vim9 syntax:

```
call filter(myList, (idx, val) => idx * val <= 42)
```

In legacy script syntax:

```
call filter(myList, {idx, val -> idx * val <= 42})
```

If you do not use "val" you can leave it out:

```
call filter(myList, {idx -> idx % 2 == 1})
```

In `Vim9` script the result must be true, false, zero or one. Other values will result in a type error.

For a `List` and a `Dictionary` the operation is done in-place. If you want it to remain unmodified make a copy first:

```
:let l = filter(copy(mylist), 'v:val =~ "KEEP"')
```

Returns `{expr1}`, the `List` or `Dictionary` that was filtered, or a new `Blob` or `String`.

When an error is encountered while evaluating `{expr2}` no further items in `{expr1}` are processed.

When `{expr2}` is a Funcref errors inside a function are ignored, unless it was defined with the "abort" flag.

Can also be used as a `method` :

```
mylist->filter(expr2)
```

Return type: `String` , `Blob` , `list<{type}>` or `dict<{type}>` depending on `{expr1}`

`finddir({name} [, {path} [, {count}]])` `finddir()`

Find directory `{name}` in `{path}`. Supports both downwards and upwards recursive directory searches. See `file-searching` for the syntax of `{path}`.

Returns the path of the first found match. When the found directory is below the current directory a relative path is returned. Otherwise a full path is returned.

If `{path}` is omitted or empty then `'path'` is used.

If the optional `{count}` is given, find `{count}`'s occurrence of `{name}` in `{path}` instead of the first one.

When `{count}` is negative return all the matches in a `List`.

Returns an empty string if the directory is not found.

This is quite similar to the ex-command ``:find``.

Can also be used as a `method` :

```
GetName()->finddir()
```

Return type: `String`

`findfile({name} [, {path} [, {count}]])` `findfile()`

Just like `finddir()`, but find a file instead of a directory. Uses `'suffixesadd'`.

Example:

```
:echo findfile("tags.vim", ".;")
```

Searches from the directory of the current file upwards until it finds the file "tags.vim".

Can also be used as a `method` :  
`GetName()->findfile()`

Return type: `String`

`flatten({list} [, {maxdepth}])` `flatten()`  
Flatten `{list}` up to `{maxdepth}` levels. Without `{maxdepth}` the result is a `List` without nesting, as if `{maxdepth}` is a very large number.  
The `{list}` is changed in place, use `flattennew()` if you do not want that.  
In Vim9 script `flatten()` cannot be used, you must always use `flattennew()` .

`E900`

`{maxdepth}` means how deep in nested lists changes are made.  
`{list}` is not modified when `{maxdepth}` is 0.  
`{maxdepth}` must be positive number.

If there is an error the number zero is returned.

Example:

```
:echo flatten([1, [2, [3, 4]], 5])
[1, 2, 3, 4, 5]
:echo flatten([1, [2, [3, 4]], 5], 1)
[1, 2, [3, 4], 5]
```

Can also be used as a `method` :  
`mylist->flatten()`

Return type: `list<{type}>`

`flattennew({list} [, {maxdepth}])` `flattennew()`  
Like `flatten()` but first make a copy of `{list}`.

Return type: `list<{type}>`

`float2nr({expr})` `float2nr()`  
Convert `{expr}` to a `Number` by omitting the part after the decimal point.  
`{expr}` must evaluate to a `Float` or a `Number` .  
Returns 0 if `{expr}` is not a `Float` or a `Number` .  
When the value of `{expr}` is out of range for a `Number` the result is truncated to `0x7fffffff` or `-0x7fffffff` (or when 64-bit `Number` support is enabled, `0x7fffffffffffffff` or `-0x7fffffffffffffff`). `NaN` results in `-0x80000000` (or when 64-bit `Number` support is enabled, `-0x8000000000000000`).

Examples:

```
echo float2nr(3.95)
3
echo float2nr(-23.45)
```

```

-23
 echo float2nr(1.0e100)
2147483647 (or 9223372036854775807)
 echo float2nr(-1.0e150)
-2147483647 (or -9223372036854775807)
 echo float2nr(1.0e-100)
0

```

Can also be used as a `method` :  
`Compute()->float2nr()`

Return type: `Number`

`floor({expr})` `floor()`

Return the largest integral value less than or equal to `{expr}` as a `Float` (round down).

`{expr}` must evaluate to a `Float` or a `Number` .

Returns 0.0 if `{expr}` is not a `Float` or a `Number` .

Examples:

```

 echo floor(1.856)
1.0
 echo floor(-5.456)
-6.0
 echo floor(4.0)
4.0

```

Can also be used as a `method` :  
`Compute()->floor()`

Return type: `Float`

`fmod({expr1}, {expr2})` `fmod()`

Return the remainder of `{expr1} / {expr2}`, even if the division is not representable. Returns `{expr1} - i * {expr2}` for some integer `i` such that if `{expr2}` is non-zero, the result has the same sign as `{expr1}` and magnitude less than the magnitude of `{expr2}`. If `{expr2}` is zero, the value returned is zero. The value returned is a `Float` .

`{expr1}` and `{expr2}` must evaluate to a `Float` or a `Number` .

Returns 0.0 if `{expr1}` or `{expr2}` is not a `Float` or a `Number` .

Examples:

```

 :echo fmod(12.33, 1.22)
0.13
 :echo fmod(-12.33, 1.22)
-0.13

```

Can also be used as a `method` :  
`Compute()->fmod(1.22)`

Return type: `Float`

`fnameescape({string})` `fnameescape()`

Escape `{string}` for use as file name command argument. All characters that have a special meaning, such as '%' and '|' are escaped with a backslash. For most systems the characters escaped are `" \t\n*?[\`$\%#\`" |!<"`. For systems where a backslash appears in a filename, it depends on the value of `'isfname'`. A leading '+' and '>' is also escaped (special after `:edit` and `:write`). And a "-" by itself (special after `:cd`). Returns an empty string on error.

Example:

```
:let fname = '+some str%nge|name'
:exe "edit " .. fnameescape(fname)
```

results in executing:

```
edit \+some\ str\%nge\|name
```

Can also be used as a `method` :

```
GetName()->fnameescape()
```

Return type: `String`

`fnamemodify({fname}, {mods})` `fnamemodify()`

Modify file name `{fname}` according to `{mods}`. `{mods}` is a string of characters like it is used for file names on the command line. See `filename-modifiers`.

Example:

```
:echo fnamemodify("main.c", ":p:h")
```

results in:

```
/home/user/vim/vim/src
```

If `{mods}` is empty or an unsupported modifier is used then `{fname}` is returned.

When `{fname}` is empty then with `{mods} ":h"` returns ".", so that `:cd`` can be used with it. This is different from `expand('%:h')` without a buffer name, which returns an empty string.

**Note:** Environment variables don't work in `{fname}`, use `expand()` first then.

Can also be used as a `method` :

```
GetName()->fnamemodify(':p:h')
```

Return type: `String`

`foldclosed({lnum})` `foldclosed()`

The result is a Number. If the line `{lnum}` is in a closed fold, the result is the number of the first line in that fold. If the line `{lnum}` is not in a closed fold, -1 is returned. `{lnum}` is used like with `getline()`. Thus "." is the current line, "m" mark m, etc.

Can also be used as a `method` :

`GetLnum()->foldclosed()`

Return type: `Number`

`foldclosedend({lnum})`

`foldclosedend()`

The result is a `Number`. If the line `{lnum}` is in a closed fold, the result is the number of the last line in that fold. If the line `{lnum}` is not in a closed fold, -1 is returned. `{lnum}` is used like with `getline()`. Thus "." is the current line, "'m" mark m, etc.

Can also be used as a `method` :

`GetLnum()->foldclosedend()`

Return type: `Number`

`foldlevel({lnum})`

`foldlevel()`

The result is a `Number`, which is the foldlevel of line `{lnum}` in the current buffer. For nested folds the deepest level is returned. If there is no fold at line `{lnum}`, zero is returned. It doesn't matter if the folds are open or closed. When used while updating folds (from '`foldexpr`') -1 is returned for lines where folds are still to be updated and the foldlevel is unknown. As a special case the level of the previous line is usually available. `{lnum}` is used like with `getline()`. Thus "." is the current line, "'m" mark m, etc.

Can also be used as a `method` :

`GetLnum()->foldlevel()`

Return type: `Number`

`foldtext()`

`foldtext()`

Returns a `String`, to be displayed for a closed fold. This is the default function used for the '`foldtext`' option and should only be called from evaluating '`foldtext`'. It uses the `v:foldstart`, `v:foldend` and `v:folddashes` variables. The returned string looks like this:

```
+-- 45 lines: abcdef
```

The number of leading dashes depends on the foldlevel. The "45" is the number of lines in the fold. "abcdef" is the text in the first non-blank line of the fold. Leading white space, "/" or "/"\* and the text from the '`foldmarker`' and '`commentstring`' options is removed.

When used to draw the actual foldtext, the rest of the line will be filled with the fold char from the '`fillchars`' setting.

Returns an empty string when there is no fold.

Return type: `String`

{not available when compiled without the |+folding| feature}

`foldtextresult({lnum})` `foldtextresult()`  
Returns the text that is displayed for the closed fold at line `{lnum}`. Evaluates `'foldtext'` in the appropriate context. When there is no closed fold at `{lnum}` an empty string is returned.  
`{lnum}` is used like with `getline()`. Thus `."` is the current line, `"'m"` mark m, etc.  
Useful when exporting folded text, e.g., to HTML.  
`{not available when compiled without the |+folding| feature}`

Can also be used as a `method` :  
`GetLnum()->foldtextresult()`

Return type: `String`

`foreach({expr1}, {expr2})` `foreach()`  
`{expr1}` must be a `List`, `String`, `Blob` or `Dictionary`.  
For each item in `{expr1}` execute `{expr2}`. `{expr1}` is not modified; its values may be, as with `:lockvar 1. E741`  
See `map()` and `filter()` to modify `{expr1}`.  
  
`{expr2}` must be a `string` or `Funcref`.

If `{expr2}` is a `string`, inside `{expr2}` `v:val` has the value of the current item. For a `Dictionary` `v:key` has the key of the current item and for a `List` `v:key` has the index of the current item. For a `Blob` `v:key` has the index of the current byte. For a `String` `v:key` has the index of the current character.

Examples:

```
call foreach(mylist, 'used[v:val] = true')
```

This records the items that are in the `{expr1}` list.

**Note** that `{expr2}` is the result of expression and is then used as a command. Often it is good to use a `literal-string` to avoid having to double backslashes.

If `{expr2}` is a `Funcref` it must take two arguments:

1. the key or the index of the current item.
2. the value of the current item.

With a legacy script lambda you don't get an error if it only accepts one argument, but with a Vim9 lambda you get "E1106: One argument too many", the number of arguments must match. If the function returns a value, it is ignored.

Returns `{expr1}` in all cases.

When an error is encountered while executing `{expr2}` no further items in `{expr1}` are processed.

When `{expr2}` is a `Funcref` errors inside a function are ignored, unless it was defined with the "abort" flag.

Can also be used as a `method` :  
`mylist->foreach(expr2)`

Return type: `String` , `Blob` `list<{type}>` or `dict<{type}>`  
depending on `{expr1}`

`foreground()` `foreground()`  
Move the Vim window to the foreground. Useful when sent from a client to a Vim server. `remote_send()`  
On Win32 systems this might not work, the OS does not always allow a window to bring itself to the foreground. Use `remote_foreground()` instead.

Return type: `Number`  
{only in the Win32, Motif and GTK GUI versions and the Win32 console version}

`fullcommand({name} [, {vim9}])` `fullcommand()`  
Get the full command name from a short abbreviated command name; see [20.2](#) for details on command abbreviations.

The string argument `{name}` may start with a ``:`` and can include a `[range]`, these are skipped and not returned. Returns an empty string if a command doesn't exist, if it's ambiguous (for user-defined commands) or cannot be shortened this way. `vim9-no-shorten`

Without the `{vim9}` argument uses the current script version. If `{vim9}` is present and FALSE then legacy script rules are used. When `{vim9}` is present and TRUE then Vim9 rules are used, e.g. "en" is not a short form of "endif".

For example ``fullcommand('s')``, ``fullcommand('sub')``, ``fullcommand(':%substitute')`` all return "substitute".

Can also be used as a `method` :  
`GetName()->fullcommand()`

Return type: `String`

`funcref({name} [, {arglist}] [, {dict}])` `funcref()`  
Just like `function()` , but the returned Funcref will lookup the function by reference, not by name. This matters when the function `{name}` is redefined later.

Unlike `function()` , `{name}` must be an existing user function. It only works for an autoloading function if it has already been loaded (to avoid mistakenly loading the autoload script when only intending to use the function name, use `function()` instead). `{name}` cannot be a builtin function. Returns 0 on error.

Can also be used as a `method` :  
`GetFuncname()->funcref([arg])`

Return type: `func(...)`: any or `Number` on error

`function({name} [, {arglist}] [, {dict}])` `function()` `partial` E700 E923  
Return a `Funcref` variable that refers to function `{name}`.  
`{name}` can be the name of a user defined function or an internal function.

`{name}` can also be a `Funcref` or a `partial`. When it is a `partial` the `dict` stored in it will be used and the `{dict}` argument is not allowed. E.g.:

```
let FuncWithArg = function(dict.Func, [arg])
let Broken = function(dict.Func, [arg], dict)
```

When using the `Funcref` the function will be found by `{name}`, also when it was redefined later. Use `funcref()` to keep the same function.

When `{arglist}` or `{dict}` is present this creates a `partial`. That means the argument list and/or the dictionary is stored in the `Funcref` and will be used when the `Funcref` is called.

The arguments are passed to the function in front of other arguments, but after any argument from `method` . Example:

```
func Callback(arg1, arg2, name)
...
let Partial = function('Callback', ['one', 'two'])
...
call Partial('name')
```

Invokes the function as with:  
`call Callback('one', 'two', 'name')`

With a `method` :  
`func Callback(one, two, three)`  
...  
`let Partial = function('Callback', ['two'])`  
...  
`eval 'one'->Partial('three')`

Invokes the function as with:  
`call Callback('one', 'two', 'three')`

The `function()` call can be nested to add more arguments to the `Funcref`. The extra arguments are appended to the list of arguments. Example:

```
func Callback(arg1, arg2, name)
"...
let Func = function('Callback', ['one'])
let Func2 = function(Func, ['two'])
"...
call Func2('name')
```

Invokes the function as with:

```
call Callback('one', 'two', 'name')
```

The Dictionary is only useful when calling a "dict" function.

In that case the {dict} is passed in as "self". Example:

```
function Callback() dict
 echo "called for " .. self.name
endfunction
"...
let context = {"name": "example"}
let Func = function('Callback', context)
"...
call Func() " will echo: called for example
```

The use of function() is not needed when there are no extra arguments, these two are equivalent, if Callback() is defined as context.Callback():

```
let Func = function('Callback', context)
let Func = context.Callback
```

The argument list and the Dictionary can be combined:

```
function Callback(arg1, count) dict
"...
let context = {"name": "example"}
let Func = function('Callback', ['one'], context)
"...
call Func(500)
```

Invokes the function as with:

```
call context.Callback('one', 500)
```

Returns 0 on error.

Can also be used as a `method` :

```
GetFuncname()->function([arg])
```

Return type: func(...): any or `Number` on error

`garbagecollect([{atexit}])`

`garbagecollect()`  
Cleanup unused `Lists` , `Dictionaries` , `Channels` and `Jobs` that have circular references.

There is hardly ever a need to invoke this function, as it is automatically done when Vim runs out of memory or is waiting for the user to press a key after `'updatetime'`. Items without circular references are always freed when they become unused. This is useful if you have deleted a very big `List` and/or `Dictionary` with circular references in a script that runs for a long time.

When the optional {atexit} argument is one, garbage collection will also be done when exiting Vim, if it wasn't done before. This is useful when checking for memory leaks.

The garbage collection is not done immediately but only when

it's safe to perform. This is when waiting for the user to type a character. To force garbage collection immediately use `test_garbagecollect_now()` .

Return type: `String`

`get({list}, {idx} [, {default}])` `get()` `get()-list`  
Get item `{idx}` from `List` `{list}`. When this item is not available return `{default}`. Return zero when `{default}` is omitted.  
Preferably used as a `method` :  
`mylist->get(idx)`

Return type: any, depending on `{list}`

`get({blob}, {idx} [, {default}])` `get()-blob`  
Get byte `{idx}` from `Blob` `{blob}`. When this byte is not available return `{default}`. Return -1 when `{default}` is omitted.  
Preferably used as a `method` :  
`myblob->get(idx)`

Return type: `Number`

`get({dict}, {key} [, {default}])` `get()-dict`  
Get item with key `{key}` from `Dictionary` `{dict}`. When this item is not available return `{default}`. Return zero when `{default}` is omitted. Useful example:  
`let val = get(g:, 'var_name', 'default')`  
This gets the value of `g:var_name` if it exists, and uses `'default'` when it does not exist.  
Preferably used as a `method` :  
`mydict->get(key)`

Return type: any, depending on `{dict}`

`get({func}, {what})` `get()-func`  
Get item `{what}` from `Funcref` `{func}`. Possible values for `{what}` are:  
"name" The function name  
"func" The function  
"dict" The dictionary  
"args" The list with arguments  
"arity" A dictionary with information about the number of arguments accepted by the function (minus the `{arglist}`) with the following fields:  
    required the number of positional arguments  
    optional the number of optional arguments, in addition to the required ones  
    varargs `TRUE` if the function accepts a variable number of arguments ...

**Note:** There is no error, if the `{arglist}` of

the Funcref contains more arguments than the Funcref expects, it's not validated.

Returns zero on error.

Preferably used as a `method` :  
`myfunc->get(what)`

Return type: any, depending on `{func}` and `{what}`

`getbufinfo()`

`getbufinfo([buf])`  
`getbufinfo([dict])`

Get information about buffers as a List of Dictionaries.

Without an argument information about all the buffers is returned.

When the argument is a `Dictionary` only the buffers matching the specified criteria are returned. The following keys can be specified in `{dict}`:

<code>buflisted</code>	include only listed buffers.
<code>bufloaded</code>	include only loaded buffers.
<code>bufmodified</code>	include only modified buffers.

Otherwise, `{buf}` specifies a particular buffer to return information for. For the use of `{buf}`, see `bufname()` above. If the buffer is found the returned List has one item. Otherwise the result is an empty list.

Each returned List item is a dictionary with the following entries:

<code>bufnr</code>	Buffer number.
<code>changed</code>	TRUE if the buffer is modified.
<code>changedtick</code>	Number of changes made to the buffer.
<code>command</code>	TRUE if the buffer belongs to the command-line window <code>cmdwin</code> .
<code>hidden</code>	TRUE if the buffer is hidden.
<code>lastused</code>	Timestamp in seconds, like <code>localtime()</code> , when the buffer was last used. <code>{only with the  +viminfo  feature}</code>
<code>listed</code>	TRUE if the buffer is listed.
<code>lnum</code>	Line number used for the buffer when opened in the current window. Only valid if the buffer has been displayed in the window in the past. If you want the line number of the last known cursor position in a given window, use <code>line()</code> : <code>:echo line('.', {winid})</code>
<code>linecount</code>	Number of lines in the buffer (only valid when loaded)

loaded	TRUE if the buffer is loaded.
name	Full path to the file in the buffer.
signs	List of signs placed in the buffer. Each list item is a dictionary with the following fields: id    sign identifier lnum  line number name  sign name
variables	A reference to the dictionary with buffer-local variables.
windows	List of <code>window-ID</code> s that display this buffer
popups	List of popup <code>window-ID</code> s that display this buffer

Examples:

```

for buf in getbufinfo()
 echo buf.name
endfor
for buf in getbufinfo({'buflisted':1})
 if buf.changed

 endif
endfor

```

To get buffer-local options use:

```
getbufvar({bufnr}, '&option_name')
```

Can also be used as a `method` :

```
GetBufnr()->getbufinfo()
```

Return type: list<dict<any>>

`getbufline()`

```
getbufline({buf}, {lnum} [, {end}])
```

Return a `List` with the lines starting from `{lnum}` to `{end}` (inclusive) in the buffer `{buf}`. If `{end}` is omitted, a `List` with only the line `{lnum}` is returned. See ``getbufoneline()`` for only getting the line.

For the use of `{buf}`, see `bufname()` above.

For `{lnum}` and `{end}` "\$" can be used for the last line of the buffer. Otherwise a number must be used.

When `{lnum}` is smaller than 1 or bigger than the number of lines in the buffer, an empty `List` is returned.

When `{end}` is greater than the number of lines in the buffer, it is treated as `{end}` is set to the number of lines in the buffer. When `{end}` is before `{lnum}` an empty `List` is returned.

This function works only for loaded buffers. For unloaded and non-existing buffers, an empty `List` is returned.

Example:

```
:let lines = getbuflines(bufnr("myfile"), 1, "$")
```

Can also be used as a `method` :

```
GetBufnr()->getbuflines(lnum)
```

Return type: `list<string>`

`getbufoneline()`

`getbufoneline({buf}, {lnum})`

Just like `getbuflines()` but only get one line and return it as a string.

Return type: `String`

`getbufvar({buf}, {varname} [, {def}])`

`getbufvar()`

The result is the value of option or local buffer variable `{varname}` in buffer `{buf}`. **Note** that the name without "b:" must be used.

The `{varname}` argument is a string.

When `{varname}` is empty returns a `Dictionary` with all the buffer-local variables.

When `{varname}` is equal to "&" returns a `Dictionary` with all the buffer-local options.

Otherwise, when `{varname}` starts with "&" returns the value of a buffer-local option.

This also works for a global or buffer-local option, but it doesn't work for a global variable, window-local variable or window-local option.

For the use of `{buf}`, see `bufname()` above.

When the buffer or variable doesn't exist `{def}` or an empty string is returned, there is no error message.

Examples:

```
:let bufmodified = getbufvar(1, "&mod")
:echo "todo myvar = " .. getbufvar("todo", "myvar")
```

Can also be used as a `method` :

```
GetBufnr()->getbufvar(varname)
```

Return type: any, depending on `{varname}`

`getcellpixels()`

`getcellpixels()`

Returns a `List` of terminal cell pixel size.

List format is `[xpixel, ypixel]`.

Only works on Unix (terminal and gVim) and Windows (gVim only). Returns `[]` on other systems or on failure.

**Note** that there could be variations across different terminals. On macOS, system Terminal.app returns sizes in points (before

Retina scaling), whereas third-party terminals return raw pixel sizes (post Retina scaling).

Return type: list<any>

`getcellwidths()` `getcellwidths()`  
Returns a `List` of cell widths of character ranges overridden by `setcellwidths()`. The format is equal to the argument of `setcellwidths()`. If no character ranges have their cell widths overridden, an empty `List` is returned.

Return type: list<any>

`getchangelist([buf])` `getchangelist()`  
Returns the `changelist` for the buffer `{buf}`. For the use of `{buf}`, see `bufname()` above. If buffer `{buf}` doesn't exist, an empty list is returned.

The returned list contains two entries: a list with the change locations and the current position in the list. Each entry in the change list is a dictionary with the following entries:

<code>col</code>	column number
<code>coladd</code>	column offset for <code>'virtualedit'</code>
<code>lnum</code>	line number

If buffer `{buf}` is the current buffer, then the current position refers to the position in the list. For other buffers, it is set to the length of the list.

Can also be used as a `method` :  
`GetBufnr()->getchangelist()`

Return type: list<any>

`getchar([expr] [, {opts}])` `getchar()`  
Get a single character from the user or input stream. If `{expr}` is omitted or is `-1`, wait until a character is available.  
If `{expr}` is `0`, only get a character when one is available. Return zero otherwise.  
If `{expr}` is `1`, only check if a character is available, it is not consumed. Return zero if no character available.  
If you prefer always getting a string use `getcharstr()`, or specify `FALSE` as "number" in `{opts}`.

Without `{expr}` and when `{expr}` is `0` a whole character or special key is returned. If it is a single character, the result is a `Number`. Use `nr2char()` to convert it to a `String`. Otherwise a `String` is returned with the encoded character. For a special key it's a `String` with a sequence of bytes starting with `0x80` (decimal: 128). This is the same value as

the String "\<Key>", e.g., "\<Left>". The returned value is also a String when a modifier (shift, control, alt) was used that is not included in the character. `keytrans()` can also be used to convert a returned String into a readable form.

When `{expr}` is 0 and Esc is typed, there will be a short delay while Vim waits to see if this is the start of an escape sequence.

When `{expr}` is 1 only the first byte is returned. For a one-byte character it is the character itself as a number. Use `nr2char()` to convert it to a String.

Use `getcharmod()` to obtain any additional modifiers.

The optional argument `{opts}` is a Dict and supports the following items:

cursor	A String specifying cursor behavior when waiting for a character. "hide": hide the cursor. "keep": keep current cursor unchanged. "msg": move cursor to message area. (default: "msg")
number	If <code>TRUE</code> , return a Number when getting a single character. If <code>FALSE</code> , the return value is always converted to a String, and an empty String (instead of 0) is returned when no character is available. (default: <code>TRUE</code> )
simplify	If <code>TRUE</code> , include modifiers in the character if possible. E.g., return the same value for <code>CTRL-I</code> and <code>&lt;Tab&gt;</code> . If <code>FALSE</code> , don't include modifiers in the character. (default: <code>TRUE</code> )

When the user clicks a mouse button, the mouse event will be returned. The position can then be found in `v:mouse_col`, `v:mouse_lnum`, `v:mouse_winid` and `v:mouse_win`. `getmousepos()` can also be used. Mouse move events will be ignored.

This example positions the mouse as it would normally happen:

```
let c = getchar()
if c == "\<LeftMouse" && v:mouse_win > 0
 exe v:mouse_win .. "wincmd w"
 exe v:mouse_lnum
 exe "normal " .. v:mouse_col .. "|"
endif
```

When using bracketed paste only the first character is

returned, the rest of the pasted text is dropped.  
`xterm-bracketed-paste` .

There is no prompt, you will somehow have to make clear to the user that a character has to be typed. The screen is not redrawn, e.g. when resizing the window. When using a popup window it should work better with a `popup-filter` .

There is no mapping for the character. Key codes are replaced, thus when the user presses the `<Del>` key you get the code for the `<Del>` key, not the raw character sequence. Examples:

```
getchar() == "\"
getchar() == "\<S-Left>"
```

This example redefines "f" to ignore case:

```
:nmap f :call FindChar(<CR>
:function FindChar()
: let c = nr2char(getchar())
: while col('.') < col('$') - 1
: normal l
: if getline('.')[col('.') - 1] ==? c
: break
: endif
: endwhile
:endfunction
```

You may also receive synthetic characters, such as `<CursorHold>` . Often you will want to ignore this and get another character:

```
:function GetKey()
: let c = getchar()
: while c == "\<CursorHold>"
: let c = getchar()
: endwhile
: return c
:endfunction
```

Return type: `Number` or `String`

`getcharmod()`

`getcharmod()`

The result is a Number which is the state of the modifiers for the last obtained character with `getchar()` or in another way. These values are added together:

```
2 shift
4 control
8 alt (meta)
16 meta (when it's different from ALT)
32 mouse double click
64 mouse triple click
96 mouse quadruple click (== 32 + 64)
128 command (Mac) or super (GTK)
```

Only the modifiers that have not been included in the character itself are obtained. Thus Shift-a results in "A"

without a modifier. Returns 0 if no modifiers are used.

Return type: [Number](#)

`getcharpos({expr})` [getcharpos\(\)](#)  
Get the position for String `{expr}`. Same as `getpos()` but the column number in the returned List is a character index instead of a byte index.  
If `getpos()` returns a very large column number, equal to `v:maxcol`, then `getcharpos()` will return the character index of the last character.

Example:

With the cursor on 'x' in line 5 with text "xxxxx":

```
getcharpos('.') returns [0, 5, 3, 0]
getpos('.') returns [0, 5, 7, 0]
```

Can also be used as a [method](#) :

```
GetMark()->getcharpos()
```

Return type: `list<number>`

`getchsearch()` [getchsearch\(\)](#)  
Return the current character search information as a `{dict}` with the following entries:

<code>char</code>	character previously used for a character search ( <code>t</code> , <code>f</code> , <code>T</code> , or <code>F</code> ); empty string if no character search has been performed
<code>forward</code>	direction of character search; 1 for forward, 0 for backward
<code>until</code>	type of character search; 1 for a <code>t</code> or <code>T</code> character search, 0 for an <code>f</code> or <code>F</code> character search

This can be useful to always have `;` and `,` search forward/backward regardless of the direction of the previous character search:

```
:nnoemap <expr> ; getchsearch().forward ? ';' : ','
:nnoemap <expr> , getchsearch().forward ? ',' : ';'

```

Also see [setchsearch\(\)](#) .

Return type: `dict<any>`

`getcharstr([ {expr} [, {opts}] ])` [getcharstr\(\)](#)  
The same as `getchar()`, except that this always returns a String, and "number" isn't allowed in `{opts}`.

Return type: [String](#)

`getcmdcomplat()` [getcmdcomplat\(\)](#)

Return completion pattern of the current command-line. Only works when the command line is being edited, thus requires use of `c_CTRL-\_e` or `c_CTRL-R_=`. Also see `getcmdtype()`, `setcmdpos()`, `getcmdline()`, `getcmdprompt()`, `getcmdcomplttype()` and `setcmdline()`. Returns an empty string when completion is not defined.

Return type: `String`

`getcmdcomplttype()` `getcmdcomplttype()`

Return the type of the current command-line completion. Only works when the command line is being edited, thus requires use of `c_CTRL-\_e` or `c_CTRL-R_=`. See `:command-completion` for the return string. Also see `getcmdtype()`, `setcmdpos()`, `getcmdline()`, `getcmdprompt()`, `getcmdcomplttype()` and `setcmdline()`. Returns an empty string when completion is not defined.

Return type: `String`

`getcmdline()` `getcmdline()`

Return the current command-line input. Only works when the command line is being edited, thus requires use of `c_CTRL-\_e` or `c_CTRL-R_=`.

Example:

```
:cmap <F7> <C-\>eescape(getcmdline(), ' \')<CR>
```

Also see `getcmdtype()`, `getcmdpos()`, `setcmdpos()`, `getcmdprompt()` and `setcmdline()`.

Returns an empty string when entering a password or using `inputsecret()`.

Return type: `String`

`getcmdpos()` `getcmdpos()`

Return the position of the cursor in the command line as a byte count. The first column is 1. Only works when editing the command line, thus requires use of `c_CTRL-\_e` or `c_CTRL-R_=` or an expression mapping. Returns 0 otherwise.

Also see `getcmdtype()`, `setcmdpos()`, `getcmdline()`, `getcmdprompt()` and `setcmdline()`.

Return type: `Number`

`getcmdprompt()` `getcmdprompt()`

Return the current command-line prompt when using functions like `input()` or `confirm()`.

Only works when the command line is being edited, thus requires use of `c_CTRL-\_e` or `c_CTRL-R_=`.

Also see `getcmdtype()`, `getcmdline()`, `getcmdpos()`,

`setcmdpos()` and `setcmdline()` .

Return type: `String`

`getcmsgscreenpos()` `getcmsgscreenpos()`

Return the screen position of the cursor in the command line as a byte count. The first column is 1. Instead of `getcmsgpos()` , it adds the prompt position. Only works when editing the command line, thus requires use of `c_CTRL-\_e` or `c_CTRL-R_=` or an expression mapping. Returns 0 otherwise. Also see `getcmsgpos()` , `setcmdpos()` , `getcmsgline()` and `setcmdline()` .

Return type: `Number`

`getcmsgdtype()` `getcmsgdtype()`

Return the current command-line type. Possible return values are:

- : normal Ex command
- > debug mode command `debug-mode`
- / forward search command
- ? backward search command
- @ `input()` command
- `:insert` or `:append` command
- = `i_CTRL-R_=`

Only works when editing the command line, thus requires use of `c_CTRL-\_e` or `c_CTRL-R_=` or an expression mapping.

Returns an empty string otherwise.

Also see `getcmsgpos()` , `setcmdpos()` and `getcmsgline()` .

Return type: `String`

`getcmsgdwintype()` `getcmsgdwintype()`

Return the current `command-line-window` type. Possible return values are the same as `getcmsgdtype()` . Returns an empty string when not in the command-line window.

Return type: `String`

`getcmsgcompletion({pat}, {type} [, {filtered}])` `getcmsgcompletion()`

Return a list of command-line completion matches. The `String` `{type}` argument specifies what for. The following completion types are supported:

<code>arglist</code>	file names in argument list
<code>augroup</code>	autocmd groups
<code>buffer</code>	buffer names
<code>behave</code>	<code>:behave</code> suboptions
<code>breakpoint</code>	<code>:breakadd</code> and <code>:breakdel</code> suboptions

color	color schemes
command	Ex command
cmdline	<code>cmdline-completion</code> result
compiler	compilers
cscope	<code>:cscope</code> suboptions
custom,{func}	custom completion, defined via {func}
customlist,{func}	custom completion, defined via {func}
diff_buffer	<code>:diffget</code> and <code>:diffput</code> completion
dir	directory names
dir_in_path	directory names in 'cdpath'
environment	environment variable names
event	autocommand events
expression	Vim expression
file	file and directory names
file_in_path	file and directory names in 'path'
filetype	filetype names 'filetype'
function	function name
help	help subjects
highlight	highlight groups
history	<code>:history</code> suboptions
keymap	keyboard mappings
locale	locale names (as output of locale -a)
mapclear	buffer argument
mapping	mapping name
menu	menus
messages	<code>:messages</code> suboptions
option	options
packadd	optional package <code>pack-add</code> names
runtime	<code>:runtime</code> completion
scriptnames	sourced script names <code>:scriptnames</code>
shellcmd	Shell command
shellcmdline	Shell command line with filename arguments
sign	<code>:sign</code> suboptions
syntax	syntax file names 'syntax'
syntime	<code>:syntime</code> suboptions
tag	tags
tag_listfiles	tags, file names
user	user names
var	user variables

If {pat} is an empty string, then all the matches are returned. Otherwise only items matching {pat} are returned. See `wildcards` for the use of special characters in {pat}.

If the optional {filtered} flag is set to 1, then 'wildignore' is applied to filter the results. Otherwise all the matches are returned. The 'wildignorecase' option always applies.

If the 'wildoptions' option contains 'fuzzy', then fuzzy matching is used to get the completion matches. Otherwise regular expression matching is used. Thus this function follows the user preference, what happens on the command line. If you do not want this you can make 'wildoptions' empty before calling getcompletion() and restore it afterwards.

If `{type}` is "cmdline", then the `cmdline-completion` result is returned. For example, to complete the possible values after a `:"call"` command:

```
echo getcompletion('call ', 'cmdline')
```

If there are no matches, an empty list is returned. An invalid value for `{type}` produces an error.

Can also be used as a `method` :

```
GetPattern()->getcompletion('color')
```

Return type: `list<string>`

`getcurpos([winid])` `getcurpos()`  
Get the position of the cursor. This is like `getpos('.')`, but includes an extra "curswant" item in the list:  
`[0, lnum, col, off, curswant]`  
The "curswant" number is the preferred column when moving the cursor vertically. After `$` command it will be a very large number equal to `v:maxcol`. Also see `getcursorcharpos()` and `getpos()`.  
The first "bufnum" item is always zero. The byte position of the cursor is returned in `'col'`. To get the character position, use `getcursorcharpos()`.

The optional `{winid}` argument can specify the window. It can be the window number or the `window-ID`. The last known cursor position is returned, this may be invalid for the current value of the buffer if it is not the current window. If `{winid}` is invalid a list with zeroes is returned.

This can be used to save and restore the cursor position:

```
let save_cursor = getcurpos()
MoveTheCursorAround
call setpos('.', save_cursor)
```

**Note** that this only works within the window. See `winrestview()` for restoring more state.

Can also be used as a `method` :

```
GetWinid()->getcurpos()
```

Return type: `list<number>`

`getcursorcharpos([winid])` `getcursorcharpos()`  
Same as `getcurpos()` but the column number in the returned List is a character index instead of a byte index.

Example:

With the cursor on 'x' in line 3 with text "xxxxx":

```
getcursorcharpos() returns [0, 3, 2, 0, 3]
getcurpos() returns [0, 3, 4, 0, 3]
```

Can also be used as a `method` :  
`GetWinid()->getcursorcharpos()`

Return type: `list<number>`

`getcwd([winnr] [, tabnr])` `getcwd()`

The result is a String, which is the name of the current working directory. `'autochdir'` is ignored.

With `winnr` return the local current directory of this window in the current tab page. `winnr` can be the window number or the `window-ID` .

If `winnr` is `-1` return the name of the global working directory. See also `haslocaldir()` .

With `winnr` and `tabnr` return the local current directory of the window in the specified tab page. If `winnr` is `-1` return the working directory of the tabpage.

If `winnr` is zero use the current window, if `tabnr` is zero use the current tabpage.

Without any arguments, return the actual working directory of the current window.

Return an empty string if the arguments are invalid.

Examples:

```
" Get the working directory of the current window
:echo getcwd()
:echo getcwd(0)
:echo getcwd(0, 0)
" Get the working directory of window 3 in tabpage 2
:echo getcwd(3, 2)
" Get the global working directory
:echo getcwd(-1)
" Get the working directory of tabpage 3
:echo getcwd(-1, 3)
" Get the working directory of current tabpage
:echo getcwd(-1, 0)
```

Can also be used as a `method` :  
`GetWinnr()->getcwd()`

Return type: `String`

`getenv({name})` `getenv()`

Return the value of environment variable `{name}`. The `{name}` argument is a string, without a leading '\$'. Example:

```
myHome = getenv('HOME')
```

When the variable does not exist `v:null` is returned. That is different from a variable set to an empty string, although some systems interpret the empty value as the variable being deleted. See also `expr-env` .

Can also be used as a [method](#) :  
`GetVname()->getenv()`

Return type: [String](#) or [Number](#)

`getfontname([name])`

[getfontname\(\)](#)

Without an argument returns the name of the normal font being used. Like what is used for the Normal highlight group `hl-Normal` .

With an argument a check is done whether String `{name}` is a valid font name. If not then an empty string is returned. Otherwise the actual font name is returned, or `{name}` if the GUI does not support obtaining the real name.

Only works when the GUI is running, thus not in your vimrc or gvimrc file. Use the [GUIEnter](#) autocommand to use this function just after the GUI has started.

**Note** that the GTK GUI accepts any font name, thus checking for a valid name does not work.

Return type: [String](#)

`getfperm({fname})`

[getfperm\(\)](#)

The result is a String, which is the read, write, and execute permissions of the given file `{fname}`.

If `{fname}` does not exist or its directory cannot be read, an empty string is returned.

The result is of the form "rwxrwxrwx", where each group of "rwx" flags represent, in turn, the permissions of the owner of the file, the group the file belongs to, and other users. If a user does not have a given permission the flag for this is replaced with the string "-". Examples:

```
:echo getfperm("/etc/passwd")
:echo getfperm(expand("~/vimrc"))
```

This will hopefully (from a security point of view) display the string "rw-r--r--" or even "rw-----".

Can also be used as a [method](#) :  
`GetFilename()->getfperm()`

Return type: [String](#)

For setting permissions use [setfperm\(\)](#) .

`getfsize({fname})`

[getfsize\(\)](#)

The result is a Number, which is the size in bytes of the given file `{fname}`.

If `{fname}` is a directory, 0 is returned.

If the file `{fname}` can't be found, -1 is returned.

If the size of `{fname}` is too big to fit in a Number then -2 is returned.

Can also be used as a `method` :  
`GetFilename()->getfsize()`

Return type: `Number`

`getftime({fname})` `getftime()`

The result is a `Number`, which is the last modification time of the given file `{fname}`. The value is measured as seconds since 1st Jan 1970, and may be passed to `strftime()`. See also `localtime()` and `strftime()`.

If the file `{fname}` can't be found -1 is returned.

Can also be used as a `method` :  
`GetFilename()->getftime()`

Return type: `Number`

`getftype({fname})` `getftype()`

The result is a `String`, which is a description of the kind of file of the given file `{fname}`.

If `{fname}` does not exist an empty string is returned.

Here is a table over different kinds of files and their results:

Normal file	"file"
Directory	"dir"
Symbolic link	"link"
Block device	"bdev"
Character device	"cdev"
Socket	"socket"
FIFO	"fifo"
All other	"other"

Example:

```
getftype("/home")
```

**Note** that a type such as "link" will only be returned on systems that support it. On some systems only "dir" and "file" are returned. On MS-Windows a symbolic link to a directory returns "dir" instead of "link".

Can also be used as a `method` :  
`GetFilename()->getftype()`

Return type: `String`

`getimstatus()` `getimstatus()`

The result is a `Number`, which is `TRUE` when the IME status is active and `FALSE` otherwise. See `'imstatusfunc'`.

Return type: `Number`

`getjumplist([winnr] [, {tabnr}])` `getjumplist()`  
Returns the `jumplist` for the specified window.

Without arguments use the current window.

With `{winnr}` only use this window in the current tab page.

`{winnr}` can also be a `window-ID`.

With `{winnr}` and `{tabnr}` use the window in the specified tab page. If `{winnr}` or `{tabnr}` is invalid, an empty list is returned.

The returned list contains two entries: a list with the jump locations and the last used jump position number in the list. Each entry in the jump location list is a dictionary with the following entries:

<code>bufnr</code>	buffer number
<code>col</code>	column number
<code>coladd</code>	column offset for <code>'virtualedit'</code>
<code>filename</code>	filename if available
<code>lnum</code>	line number

Can also be used as a `method` :

`GetWinnr()->getjumplist()`

Return type: `list<any>`

`getline({lnum} [, {end}])` `getline()`  
Without `{end}` the result is a `String`, which is line `{lnum}` from the current buffer. Example:

```
getline(1)
```

When `{lnum}` is a `String` that doesn't start with a digit, `line()` is called to translate the `String` into a `Number`.

To get the line under the cursor:

```
getline(".")
```

When `{lnum}` is a number smaller than 1 or bigger than the number of lines in the buffer, an empty string is returned.

When `{end}` is given the result is a `List` where each item is a line from the current buffer in the range `{lnum}` to `{end}`, including line `{end}`.

`{end}` is used in the same way as `{lnum}`.

Non-existing lines are silently omitted.

When `{end}` is before `{lnum}` an empty `List` is returned.

Example:

```
:let start = line('.')
:let end = search("^\$") - 1
:let lines = getline(start, end)
```

Can also be used as a `method` :

`ComputeLnum()->getline()`

Return type: `list<string>` or `String` depending on `{end}`

To get lines from another buffer see `getbufline()` and

`getbufoneline()`

`getloclist({nr} [, {what}])`

`getloclist()`

Returns a `List` with all the entries in the location list for window `{nr}`. `{nr}` can be the window number or the `window-ID`. When `{nr}` is zero the current window is used.

For a location list window, the displayed location list is returned. For an invalid window number `{nr}`, an empty list is returned. Otherwise, same as `getqflist()`.

If the optional `{what}` dictionary argument is supplied, then returns the items listed in `{what}` as a dictionary. Refer to `getqflist()` for the supported items in `{what}`.

In addition to the items supported by `getqflist()` in `{what}`, the following item is supported by `getloclist()`:

<code>filewinid</code>	id of the window used to display files from the location list. This field is applicable only when called from a location list window. See <code>location-list-file-window</code> for more details.
------------------------	----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

Returns a `Dictionary` with default values if there is no location list for the window `{nr}`.

Returns an empty `Dictionary` if window `{nr}` does not exist.

Examples (See also `getqflist-examples`):

```
:echo getloclist(3, {'all': 0})
:echo getloclist(5, {'filewinid': 0})
```

Return type: `list<dict<any>>` or `list<any>`

`getmarklist([ {buf} ])`

`getmarklist()`

Without the `{buf}` argument returns a `List` with information about all the global marks. `mark`

If the optional `{buf}` argument is specified, returns the local marks defined in buffer `{buf}`. For the use of `{buf}`, see `bufname()`. If `{buf}` is invalid, an empty list is returned.

Each item in the returned `List` is a `Dict` with the following:

<code>mark</code>	name of the mark prefixed by ""
<code>pos</code>	a <code>List</code> with the position of the mark: [ <code>bufnum</code> , <code>lnum</code> , <code>col</code> , <code>off</code> ] Refer to <code>getpos()</code> for more information.
<code>file</code>	file name

Refer to `getpos()` for getting information about a specific mark.

Can also be used as a `method` :  
`GetBufnr()->getmarklist()`

Return type: `list<dict<any>>` or `list<any>`

`getmatches([win])`

`getmatches()`

Returns a `List` with all matches previously defined for the current window by `matchadd()` and the `:match` commands.

`getmatches()` is useful in combination with `setmatches()`, as `setmatches()` can restore a list of matches saved by `getmatches()`.

If `{win}` is specified, use the window with this number or window ID instead of the current window. If `{win}` is invalid, an empty list is returned.

Example:

```
:echo getmatches()
[{'group': 'MyGroup1', 'pattern': 'TODO',
 'priority': 10, 'id': 1}, {'group': 'MyGroup2',
 'pattern': 'FIXME', 'priority': 10, 'id': 2}]
:let m = getmatches()
:call clearmatches()
:echo getmatches()
[]
:call setmatches(m)
:echo getmatches()
[{'group': 'MyGroup1', 'pattern': 'TODO',
 'priority': 10, 'id': 1}, {'group': 'MyGroup2',
 'pattern': 'FIXME', 'priority': 10, 'id': 2}]
:unlet m
```

Return type: `list<dict<any>>` or `list<any>`

`getmousepos()`

`getmousepos()`

Returns a `Dictionary` with the last known position of the mouse. This can be used in a mapping for a mouse click or in a filter of a popup window. The items are:

<code>screenrow</code>	screen row
<code>screencol</code>	screen column
<code>winid</code>	Window ID of the click
<code>winrow</code>	row inside "winid"
<code>wincol</code>	column inside "winid"
<code>line</code>	text line inside "winid"
<code>column</code>	text column inside "winid"
<code>coladd</code>	offset (in screen columns) from the start of the clicked char

All numbers are 1-based.

If not over a window, e.g. when in the command line, then only "screenrow" and "screencol" are valid, the others are zero.

When on the status line below a window or the vertical

separator right of a window, the "line" and "column" values are zero.

When the position is after the text then "column" is the length of the text in bytes plus one.

If the mouse is over a popup window then that window is used.

When using `getchar()` the Vim variables `v:mouse_lnum`, `v:mouse_col` and `v:mouse_winid` also provide these values.

Return type: dict<number>

`getmouseshape()` `getmouseshape()`  
Returns the name of the currently showing mouse pointer. When the `+mouseshape` feature is not supported or the shape is unknown an empty string is returned. This function is mainly intended for testing.

Return type: `String`

`getpid()` `getpid()`  
Return a Number which is the process ID of the Vim process. On Unix and MS-Windows this is a unique number, until Vim exits.

Return type: `Number`

`getpos({expr})` `getpos()`  
Get the position for String `{expr}`.  
The accepted values for `{expr}` are: `E1209`

- `.` The cursor position.
- `$` The last line in the current buffer.
- `'x` Position of mark `x` (if the mark is not set, `0` is returned for all values).
- `w0` First line visible in current window (one if the display isn't updated, e.g. in silent Ex mode).
- `w$` Last line visible in current window (this is one less than `w0` if no lines are visible).
- `v` When not in Visual mode, returns the cursor position. In Visual mode, returns the other end of the Visual area. A good way to think about this is that in Visual mode `"v"` and `"."` complement each other. While `"."` refers to the cursor position, `"v"` refers to where `v_o` would move the cursor. As a result, you can use `"v"` and `"."` together to work on all of a selection in characterwise Visual mode. If the cursor is at the end of a characterwise Visual area, `"v"` refers to the start of the same Visual area. And if the cursor is at the start of a characterwise Visual

area, "v" refers to the end of the same Visual area. "v" differs from '<' and '>' in that it's updated right away.

**Note** that a mark in another file can be used. The line number then applies to another buffer.

The result is a **List** with four numbers:

```
[bufnum, lnum, col, off]
```

"bufnum" is zero, unless a mark like '0 or 'A is used, then it is the buffer number of the mark.

"lnum" and "col" are the position in the buffer. The first column is 1.

The "off" number is zero, unless '**virtualedit**' is used. Then it is the offset in screen columns from the start of the character. E.g., a position within a <Tab> or after the last character.

For getting the cursor position see `getcurpos()` .

The column number in the returned List is the byte position within the line. To get the character position in the line, use `getcharpos()` .

**Note** that for '<' and '>' Visual mode matters: when it is "V" (visual line mode) the column of '<' is zero and the column of '>' is a large number equal to `v:maxcol` .

A very large column number equal to `v:maxcol` can be returned, in which case it means "after the end of the line".

If {`expr`} is invalid, returns a list with all zeros.

This can be used to save and restore the position of a mark:

```
let save_a_mark = getpos("'a")
...
call setpos("'a", save_a_mark)
```

Also see `getcharpos()` , `getcurpos()` and `setpos()` .

Can also be used as a **method** :

```
GetMark()->getpos()
```

Return type: list<number>

`getqflist([{what}])`

`getqflist()`

Returns a **List** with all the current quickfix errors. Each list item is a dictionary with these entries:

```
bufnr number of buffer that has the file name, use
 bufname() to get the name
module module name
lnum line number in the buffer (first line is 1)
end_lnum end of line number if the item is multiline
col column number (first column is 1)
end_col end of column number if the item has range
vcol TRUE : "col" is visual column
```

FALSE : "col" is byte index  
 nr error number  
 pattern search pattern used to locate the error  
 text description of the error  
 type type of the error, 'E', '1', etc.  
 valid TRUE : recognized error message  
 user\_data custom data associated with the item, can be any type.

When there is no error list or it's empty, an empty list is returned. Quickfix list entries with a non-existing buffer number are returned with "bufnr" set to zero (Note: some functions accept buffer number zero for the alternate buffer, you may need to explicitly check for zero).

Useful application: Find pattern matches in multiple files and do something with them:

```

:vimgrep /theword/jg *.c
:for d in getqflist()
: echo bufname(d.bufnr) ':' d.lnum '=' d.text
:endfor

```

If the optional `{what}` dictionary argument is supplied, then returns only the items listed in `{what}` as a dictionary. The following string items are supported in `{what}`:

changedtick get the total number of changes made to the list [quickfix-changedtick](#)  
 context get the [quickfix-context](#)  
 efm errorformat to use when parsing "lines". If not present, then the **'errorformat'** option value is used.  
 id get information for the quickfix list with [quickfix-ID](#) ; zero means the id for the current list or the list specified by "nr"  
 idx get information for the quickfix entry at this index in the list specified by **'id'** or **'nr'**. If set to zero, then uses the current entry. See [quickfix-index](#)  
 items quickfix list entries  
 lines parse a list of lines using **'efm'** and return the resulting entries. Only a [List](#) type is accepted. The current quickfix list is not modified. See [quickfix-parse](#) .  
 nr get information for this quickfix list; zero means the current quickfix list and "\$" means the last quickfix list  
 qfbufnr number of the buffer displayed in the quickfix window. Returns 0 if the quickfix buffer is not present. See [quickfix-buffer](#) .  
 size number of entries in the quickfix list  
 title get the list title [quickfix-title](#)  
 winid get the quickfix [window-ID](#)  
 all all of the above quickfix properties

Non-string items in `{what}` are ignored. To get the value of a particular item, set it to zero.  
 If "nr" is not present then the current quickfix list is used.  
 If both "nr" and a non-zero "id" are specified, then the list specified by "id" is used.  
 To get the number of lists in the quickfix stack, set "nr" to "\$" in `{what}`. The "nr" value in the returned dictionary contains the quickfix stack size.  
 When "lines" is specified, all the other items except "efm" are ignored. The returned dictionary contains the entry "items" with the list of entries.

The returned dictionary contains the following entries:

<code>changedtick</code>	total number of changes made to the list <code>quickfix-changedtick</code>
<code>context</code>	quickfix list context. See <code>quickfix-context</code> . If not present, set to "".
<code>id</code>	quickfix list ID <code>quickfix-ID</code> . If not present, set to 0.
<code>idx</code>	index of the quickfix entry in the list. If not present, set to 0.
<code>items</code>	quickfix list entries. If not present, set to an empty list.
<code>nr</code>	quickfix list number. If not present, set to 0
<code>qfbufnr</code>	number of the buffer displayed in the quickfix window. If not present, set to 0.
<code>size</code>	number of entries in the quickfix list. If not present, set to 0.
<code>title</code>	quickfix list title text. If not present, set to "".
<code>winid</code>	quickfix <code>window-ID</code> . If not present, set to 0

Examples (See also `getqflist-examples` ):

```
:echo getqflist({'all': 1})
:echo getqflist({'nr': 2, 'title': 1})
:echo getqflist({'lines' : ["F1:10:L10"]})
```

Return type: `list<dict<any>>` or `list<any>`

`getreg([ {regname} [, 1 [, {list} ] ] ])` `getreg()`

The result is a String, which is the contents of register `{regname}`. Example:

```
:let cliptext = getreg('*')
```

When register `{regname}` was not set the result is an empty string.

The `{regname}` argument must be a string. E1162

`getreg('=')` returns the last evaluated value of the expression register. (For use in maps.)

`getreg(=', 1)` returns the expression itself, so that it can be restored with `setreg()` . For other registers the extra argument is ignored, thus you can always give it.

If `{list}` is present and `TRUE` , the result type is changed to `List` . Each list item is one text line. Use it if you care about zero bytes possibly present inside register: without third argument both NLS and zero bytes are represented as NLS (see `NL-used-for-Nul` ).

When the register was not set an empty list is returned.

If `{regname}` is "", the unnamed register "" is used.

If `{regname}` is not specified, `v:register` is used.

In `Vim9-script` `{regname}` must be one character.

Can also be used as a `method` :

`GetRegname()->getreg()`

Return type: `String`

`getreginfo([{{regname}}])`

`getreginfo()`

Returns detailed information about register `{regname}` as a Dictionary with the following entries:

<code>regcontents</code>	List of lines contained in register <code>{regname}</code> , like <code>getreg({regname}, 1, 1)</code> .
<code>regtype</code>	the type of register <code>{regname}</code> , as in <code>getregtype()</code> .
<code>isunnamed</code>	Boolean flag, <code>v:true</code> if this register is currently pointed to by the unnamed register.
<code>points_to</code>	for the unnamed register, gives the single letter name of the register currently pointed to (see <code>quotequote</code> ). For example, after deleting a line with <code>`dd`</code> , this field will be "1", which is the register that got the deleted text.

The `{regname}` argument is a string. If `{regname}` is invalid or not set, an empty Dictionary will be returned.

If `{regname}` is "" or "@", the unnamed register "" is used.

If `{regname}` is not specified, `v:register` is used.

The returned Dictionary can be passed to `setreg()` .

In `Vim9-script` `{regname}` must be one character.

Can also be used as a `method` :

`GetRegname()->getreginfo()`

Return type: `dict<any>`

`getregion({pos1}, {pos2} [, {opts}])`

`getregion()`

Returns the list of strings from `{pos1}` to `{pos2}` from a buffer.

`{pos1}` and `{pos2}` must both be `List` s with four numbers.

See [getpos\(\)](#) for the format of the list. It's possible to specify positions from a different buffer, but please [note](#) the limitations at [getregion-notes](#) .

The optional argument `{opts}` is a Dict and supports the following items:

<code>type</code>	Specify the region's selection type. See <a href="#">getregtype()</a> for possible values, except that the width can be omitted and an empty string cannot be used. (default: "v")
<code>exclusive</code>	If <code>TRUE</code> , use exclusive selection for the end position. (default: follow <code>'selection'</code> )

You can get the last selection type by [visualmode\(\)](#) . If Visual mode is active, use [mode\(\)](#) to get the Visual mode (e.g., in a `:vmap` ). This function is useful to get text starting and ending in different columns, such as a [characterwise-visual](#) selection.

#### [getregion-notes](#)

**Note** that:

- Order of `{pos1}` and `{pos2}` doesn't matter, it will always return content from the upper left position to the lower right position.
- If `'virtualedit'` is enabled and the region is past the end of the lines, resulting lines are padded with spaces.
- If the region is blockwise and it starts or ends in the middle of a multi-cell character, it is not included but its selected part is substituted with spaces.
- If `{pos1}` and `{pos2}` are not in the same buffer, an empty list is returned.
- `{pos1}` and `{pos2}` must belong to a [bufloaded\(\)](#) buffer.
- It is evaluated in current window context, which makes a difference if the buffer is displayed in a window with different `'virtualedit'` or `'list'` values.

Examples:

```
:xnoremap <CR>
\ <Cmd>echow getregion(
\ getpos('v'), getpos('.'), #{ type: mode() })<CR>
```

Can also be used as a [method](#) :

```
getpos('.')->getregion(getpos("'a"))
```

Return type: list<string>

`getregionpos({pos1}, {pos2} [, {opts}])` [getregionpos\(\)](#)  
Same as [getregion\(\)](#) , but returns a list of positions describing the buffer text segments bound by `{pos1}` and

{pos2}.

The segments are a pair of positions for every line:

```
[[{start_pos}, {end_pos}], ...]
```

The position is a `List` with four numbers:

```
[bufnum, lnum, col, off]
```

"bufnum" is the buffer number.

"lnum" and "col" are the position in the buffer. The first column is 1.

If the "off" number of a starting position is non-zero, it is the offset in screen columns from the start of the character.

E.g., a position within a `<Tab>` or after the last character.

If the "off" number of an ending position is non-zero, it is the offset of the character's first cell not included in the selection, otherwise all its cells are included.

Apart from the options supported by `getregion()`, {opts} also supports the following:

eol	If <code>TRUE</code> , indicate positions beyond the end of a line with "col" values one more than the length of the line. If <code>FALSE</code> , positions are limited within their lines, and if a line is empty or the selection is entirely beyond the end of a line, a "col" value of 0 is used for both positions. (default: <code>FALSE</code> )
-----	----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

Can also be used as a `method` :

```
getpos('.')->getregionpos(getpos("a"))
```

Return type: `list<list<list<number>>>`

`getregtype([regname])`

`getregtype()`

The result is a `String`, which is type of register {regname}.

The value will be one of:

"v"	for <code>characterwise</code> text
"V"	for <code>linewise</code> text
"<CTRL-V>{width}"	for <code>blockwise-visual</code> text
""	for an empty or unknown register

`<CTRL-V>` is one character with value 0x16.

The {regname} argument is a string. If {regname} is "", the unnamed register "" is used. If {regname} is not specified, `v:register` is used.

In `Vim9-script` {regname} must be one character.

Can also be used as a `method` :

```
GetRegname()->getregtype()
```

Return type: `String`

`getscriptinfo([opts])` `getscriptinfo()`  
Returns a **List** with information about all the sourced Vim scripts in the order they were sourced, like what `:scriptnames` shows.

The optional Dict argument `{opts}` supports the following optional items:

<code>name</code>	Script name match pattern. If specified, and "sid" is not specified, information about scripts with a name that match the pattern "name" are returned.
<code>sid</code>	Script ID <code>&lt;SID&gt;</code> . If specified, only information about the script with ID "sid" is returned and "name" is ignored.

Each item in the returned List is a **Dict** with the following items:

<code>autoload</code>	Set to TRUE for a script that was used with <code>import autoload</code> but was not actually sourced yet (see <code>import-autoload</code> ).
<code>functions</code>	List of script-local function names defined in the script. Present only when a particular script is specified using the "sid" item in <code>{opts}</code> .
<code>name</code>	Vim script file name.
<code>sid</code>	Script ID <code>&lt;SID&gt;</code> .
<code>sourced</code>	Script ID of the actually sourced script that this script name links to, if any, otherwise zero
<code>variables</code>	A dictionary with the script-local variables. Present only when a particular script is specified using the "sid" item in <code>{opts}</code> . <b>Note</b> that this is a copy, the value of script-local variables cannot be changed using this dictionary.
<code>version</code>	Vim script version ( <code>scriptversion</code> )

Examples:

```
:echo getscriptinfo({'name': 'myscript'})
:echo getscriptinfo({'sid': 15})[0].variables
```

Return type: `list<dict<any>>`

`getstacktrace()` `getstacktrace()`

Returns the current stack trace of Vim scripts. Stack trace is a **List** , of which each item is a **Dictionary** with the following items:

<code>funcref</code>	The funcref if the stack is at a function, otherwise this item is omitted.
<code>event</code>	The string of the event description if the stack is at an autocmd event, otherwise this item is omitted.
<code>lnum</code>	The line number in the script on the stack.

filepath The file path of the script on the stack.

Return type: list<dict<any>>

gettabinfo([{{tabnr}}])

gettabinfo()

If `{tabnr}` is not specified, then information about all the tab pages is returned as a `List`. Each List item is a `Dictionary`. Otherwise, `{tabnr}` specifies the tab page number and information about that one is returned. If the tab page does not exist an empty List is returned.

Each List item is a `Dictionary` with the following entries:

tabnr	tab page number.
variables	a reference to the dictionary with tabpage-local variables
windows	List of <code>window-ID</code> s in the tab page.

Can also be used as a `method` :

`GetTabnr()->gettabinfo()`

Return type: list<dict<any>>

gettabvar({tabnr}, {varname} [, {def}])

gettabvar()

Get the value of a tab-local variable `{varname}` in tab page `{tabnr}`. `t:var`

Tabs are numbered starting with one.

The `{varname}` argument is a string. When `{varname}` is empty a dictionary with all tab-local variables is returned.

**Note** that the name without "t:" must be used.

When the tab or variable doesn't exist `{def}` or an empty string is returned, there is no error message.

Can also be used as a `method` :

`GetTabnr()->gettabvar(varname)`

Return type: any, depending on `{varname}`

gettabwinvar({tabnr}, {winnr}, {varname} [, {def}])

gettabwinvar()

Get the value of window-local variable `{varname}` in window `{winnr}` in tab page `{tabnr}`.

The `{varname}` argument is a string. When `{varname}` is empty a dictionary with all window-local variables is returned.

When `{varname}` is equal to "&" get the values of all window-local options in a `Dictionary`.

Otherwise, when `{varname}` starts with "&" get the value of a window-local option.

**Note** that `{varname}` must be the name without "w:".

Tabs are numbered starting with one. For the current tabpage use `getwinvar()`.

`{winnr}` can be the window number or the `window-ID`.

When `{winnr}` is zero the current window is used.

This also works for a global option, buffer-local option and window-local option, but it doesn't work for a global variable or buffer-local variable.

When the tab, window or variable doesn't exist `{def}` or an empty string is returned, there is no error message.

Examples:

```
:let list_is_on = gettabwinvar(1, 2, '&list')
:echo "myvar = " .. gettabwinvar(3, 1, 'myvar')
```

To obtain all window-local variables use:

```
gettabwinvar({tabnr}, {winnr}, '&')
```

Can also be used as a [method](#) :

```
GetTabnr()->gettabwinvar(winnr, varname)
```

Return type: any, depending on `{varname}`

`gettagstack([{winnr}])`

`gettagstack()`

The result is a Dict, which is the tag stack of window `{winnr}`.

`{winnr}` can be the window number or the [window-ID](#) .

When `{winnr}` is not specified, the current window is used.

When window `{winnr}` doesn't exist, an empty Dict is returned.

The returned dictionary contains the following entries:

<code>curidx</code>	Current index in the stack. When at top of the stack, set to (length + 1). Index of bottom of the stack is 1.
<code>items</code>	List of items in the stack. Each item is a dictionary containing the entries described below.
<code>length</code>	Number of entries in the stack.

Each item in the stack is a dictionary with the following entries:

<code>bufnr</code>	buffer number of the current jump
<code>from</code>	cursor position before the tag jump. See <a href="#">getpos()</a> for the format of the returned list.
<code>matchnr</code>	current matching tag number. Used when multiple matching tags are found for a name.
<code>tagname</code>	name of the tag

See [tagstack](#) for more information about the tag stack.

Can also be used as a [method](#) :

```
GetWinnr()->gettagstack()
```

Return type: dict<any>

`gettext({text} [, {package}])`

`gettext()`

Translate String `{text}` if possible.

This is intended for use in Vim scripts. When generating message translations the `{text}` is extracted by ``xgettext``, the translator can add translated messages into the `.po` file and Vim will lookup the translation when `gettext()` is called. For `{text}` double quoted strings are preferred, because ``xgettext`` does not support single quoted escaped text.

When the `{package}` is specified, the translation is looked up for that specific package. This is mainly required for third-party Vim scripts. You need to specify a path to the translations with the `bindtextdomain()` function before using the `gettext()` function.

Return type: `String`

`getwininfo([winid])`

`getwininfo()`

Returns information about windows as a `List` with Dictionaries.

If `{winid}` is given Information about the window with that ID is returned, as a `List` with one item. If the window does not exist the result is an empty list.

Without `{winid}` information about all the windows in all the tab pages is returned.

Each List item is a `Dictionary` with the following entries:

<code>botline</code>	last complete displayed buffer line
<code>bufnr</code>	number of buffer in the window
<code>height</code>	window height (excluding winbar)
<code>leftcol</code>	first column displayed; only used when <code>'wrap'</code> is off
<code>loclist</code>	1 if showing a location list {only with the <code>+quickfix</code> feature}
<code>quickfix</code>	1 if quickfix or location list window {only with the <code>+quickfix</code> feature}
<code>terminal</code>	1 if a terminal window {only with the <code>+terminal</code> feature}
<code>tabnr</code>	tab page number
<code>topline</code>	first displayed buffer line
<code>variables</code>	a reference to the dictionary with window-local variables
<code>width</code>	window width
<code>winbar</code>	1 if the window has a toolbar, 0 otherwise
<code>wincol</code>	leftmost screen column of the window; "col" from <code>win_screenpos()</code>
<code>textoff</code>	number of columns occupied by any <code>'foldcolumn'</code> , <code>'signcolumn'</code> and line number in front of the text
<code>winid</code>	<code>window-ID</code>
<code>winnr</code>	window number
<code>winrow</code>	topmost screen line of the window; "row" from <code>win_screenpos()</code>

Can also be used as a `method` :  
`GetWinnr()->getwininfo()`

Return type: `list<dict<any>>`

`getwinpos([{{timeout}}])`

`getwinpos()`

The result is a `List` with two numbers, the result of `getwinposx()` and `getwinposy()` combined:

`[x-pos, y-pos]`

`{timeout}` can be used to specify how long to wait in msec for a response from the terminal. When omitted 100 msec is used. Use a longer time for a remote terminal.

When using a value less than 10 and no response is received within that time, a previously reported position is returned, if available. This can be used to poll for the position and do some work in the meantime:

```
while 1
 let res = getwinpos(1)
 if res[0] >= 0
 break
 endif
 " Do some work here
endwhile
```

Can also be used as a `method` :  
`GetTimeout()->getwinpos()`

Return type: `list<number>`

`getwinposx()`

`getwinposx()`

The result is a `Number`, which is the X coordinate in pixels of the left hand side of the GUI Vim window. Also works for an xterm (uses a timeout of 100 msec).

The result will be -1 if the information is not available (e.g. on the Wayland backend).

The value can be used with ``:winpos``.

Return type: `Number`

`getwinposy()`

`getwinposy()`

The result is a `Number`, which is the Y coordinate in pixels of the top of the GUI Vim window. Also works for an xterm (uses a timeout of 100 msec).

The result will be -1 if the information is not available (e.g. on the Wayland backend).

The value can be used with ``:winpos``.

Return type: `Number`

`getwinvar({winnr}, {varname} [, {def}])` `getwinvar()`

Like `gettabwinvar()` for the current tabpage.

Examples:

```
:let list_is_on = getwinvar(2, '&list')
:echo "myvar = " .. getwinvar(1, 'myvar')
```

Can also be used as a `method` :

```
GetWinnr()->getwinvar(varname)
```

Return type: any, depending on `{varname}`

`glob({expr} [, {nosuf} [, {list} [, {alllinks}]]])` `glob()`

Expand the file wildcards in `{expr}`. See `wildcards` for the use of special characters.

Unless the optional `{nosuf}` argument is given and is `TRUE` , the `'suffixes'` and `'wildignore'` options apply: Names matching one of the patterns in `'wildignore'` will be skipped and `'suffixes'` affect the ordering of matches. `'wildignorecase'` always applies.

When `{list}` is present and it is `TRUE` the result is a `List` with all matching files. The advantage of using a `List` is, you also get filenames containing newlines correctly. Otherwise the result is a `String` and when there are several matches, they are separated by `<NL>` characters.

If the expansion fails, the result is an empty `String` or `List`.

You can also use `readdir()` if you need to do complicated things, such as limiting the number of matches.

A name for a non-existing file is not included. A symbolic link is only included if it points to an existing file. However, when the `{alllinks}` argument is present and it is `TRUE` then all symbolic links are included.

For most systems backticks can be used to get files names from any external command. Example:

```
:let tagfiles = glob("`find . -name tags -print`")
:let &tags = substitute(tagfiles, "\n", ",", "g")
```

The result of the program inside the backticks should be one item per line. Spaces inside an item are allowed.

See `expand()` for expanding special Vim variables. See `system()` for getting the raw output of an external command.

Can also be used as a `method` :

```
GetExpr()->glob()
```

Return type: `String` or `list<string>` or `list<any>` depending on `{list}`

glob2regpat({string})

glob2regpat()

Convert a file pattern, as used by glob(), into a search pattern. The result can be used to match with a string that is a file name. E.g.

```
if filename =~ glob2regpat('Make*.mak')
```

This is equivalent to:

```
if filename =~ '^Make.*\.mak$'
```

When {string} is an empty string the result is "^\$", match an empty string.

**Note** that the result depends on the system. On MS-Windows a backslash usually means a path separator.

Can also be used as a **method** :

```
GetExpr()->glob2regpat()
```

Return type: **String**

globpath({path}, {expr} [, {nosuf} [, {list} [, {alllinks}]]])

globpath()

Perform glob() for String {expr} on all directories in {path} and concatenate the results. Example:

```
:echo globpath(&rtp, "syntax/c.vim")
```

{path} is a comma-separated list of directory names. Each directory name is prepended to {expr} and expanded like with glob(). A path separator is inserted when needed.

To add a comma inside a directory name escape it with a backslash. **Note** that on MS-Windows a directory may have a trailing backslash, remove it if you put a comma after it. If the expansion fails for one of the directories, there is no error message.

Unless the optional {nosuf} argument is given and is **TRUE**, the **'suffixes'** and **'wildignore'** options apply: Names matching one of the patterns in **'wildignore'** will be skipped and **'suffixes'** affect the ordering of matches.

When {list} is present and it is **TRUE** the result is a **List** with all matching files. The advantage of using a List is, you also get filenames containing newlines correctly. Otherwise the result is a String and when there are several matches, they are separated by <NL> characters. Example:

```
:echo globpath(&rtp, "syntax/c.vim", 0, 1)
```

{alllinks} is used as with glob().

The "\*" item can be used to search in a directory tree.

For example, to find all "README.txt" files in the directories in **'runtimepath'** and below:

```
:echo globpath(&rtp, "**/README.txt")
```

Upwards search and limiting the depth of "\*" is not

supported, thus using **'path'** will not always work properly.

Can also be used as a [method](#) , the base is passed as the second argument:

```
GetExpr()->globpath(&rtp)
```

Return type: [String](#) or list<string> or list<any> depending on [{list}](#)

`has({feature} [, {check}])` [has\(\)](#)

When [{check}](#) is omitted or is zero: The result is a Number, which is 1 if the feature [{feature}](#) is supported, zero otherwise. The [{feature}](#) argument is a string, case is ignored. See [feature-list](#) below.

When [{check}](#) is present and not zero: The result is a Number, which is 1 if the feature [{feature}](#) could ever be supported, zero otherwise. This is useful to check for a typo in [{feature}](#) and to detect dead code. Keep in mind that an older [Vim version](#) will not know about a feature added later and features that have been abandoned will not be known by the current Vim version.

Also see [exists\(\)](#) and [exists\\_compiled\(\)](#) .

**Note** that to skip code that has a syntax error when the feature is not available, Vim may skip the rest of the line and miss a following ``endif``. Therefore put the ``endif`` on a separate line:

```
if has('feature')
 let x = this->breaks->without->the->feature
endif
```

If the ``endif`` would be moved to the second line as `"| endif"` it would not be found.

Return type: [Number](#)

`has_key({dict}, {key})` [has\\_key\(\)](#)

The result is a Number, which is TRUE if [Dictionary {dict}](#) has an entry with key [{key}](#). FALSE otherwise. The [{key}](#) argument is a string. In [Vim9](#) script a number is also accepted (and converted to a string) but no other types. In legacy script the usual automatic conversion to string is done.

Can also be used as a [method](#) :  
`mydict->has_key(key)`

Return type: [Number](#)

`haslocaldir([winnr] [, {tabnr}])` [haslocaldir\(\)](#)

The result is a Number:

- 1 when the window has set a local directory via `:lcd`
- 2 when the tab-page has set a local directory via `:tcd`
- 0 otherwise.

Without arguments use the current window.

With `{winnr}` use this window in the current tab page.

With `{winnr}` and `{tabnr}` use the window in the specified tab page.

`{winnr}` can be the window number or the `window-ID` .

If `{winnr}` is -1 it is ignored and only the tabpage is used.

Return 0 if the arguments are invalid.

Examples:

```

if haslocaldir() == 1
 " window local directory case
elseif haslocaldir() == 2
 " tab-local directory case
else
 " global directory case
endif

" current window
:echo haslocaldir()
:echo haslocaldir(0)
:echo haslocaldir(0, 0)
" window n in current tab page
:echo haslocaldir(n)
:echo haslocaldir(n, 0)
" window n in tab page m
:echo haslocaldir(n, m)
" tab page m
:echo haslocaldir(-1, m)

```

Can also be used as a `method` :

```
GetWinnr()->haslocaldir()
```

Return type: `Number`

`hasmapto({what} [, {mode} [, {abbr}]])` `hasmapto()`

The result is a `Number`, which is `TRUE` if there is a mapping that contains `{what}` in somewhere in the rhs (what it is mapped to) and this mapping exists in one of the modes indicated by `{mode}`.

The arguments `{what}` and `{mode}` are strings.

When `{abbr}` is there and it is `TRUE` use abbreviations instead of mappings. Don't forget to specify Insert and/or Command-line mode.

Both the global mappings and the mappings local to the current buffer are checked for a match.

If no matching mapping is found `FALSE` is returned.

The following characters are recognized in `{mode}`:

n	Normal mode
v	Visual and Select mode
x	Visual mode

```

s Select mode
o Operator-pending mode
i Insert mode
l Language-Argument ("r", "f", "t", etc.)
c Command-line mode

```

When `{mode}` is omitted, "nvo" is used.

This function is useful to check if a mapping already exists to a function in a Vim script. Example:

```

:if !hasmapto('\ABCdoit')
: map <Leader>d \ABCdoit
:endif

```

This installs the mapping to "\ABCdoit" only if there isn't already a mapping to "\ABCdoit".

Can also be used as a `method` :  
`GetRHS()->hasmapto()`

Return type: `Number`

`histadd({history}, {item})`

`histadd()`

Add the String `{item}` to the history `{history}` which can be one of:

`hist-names`

```

"cmd" or ":" command line history
"search" or "/" search pattern history
"expr" or "=" typed expression history
"input" or "@" input line history
"debug" or ">" debug command history
empty or "" the current or last used history

```

The `{history}` string does not need to be the whole name, one character is sufficient.

If `{item}` does already exist in the history, it will be shifted to become the newest entry.

The result is a `Number`: TRUE if the operation was successful, otherwise FALSE is returned.

Example:

```

:call histadd("input", strftime("%Y %b %d"))
:let date=input("Enter date: ")

```

This function is not available in the `sandbox` .

Can also be used as a `method` , the base is passed as the second argument:

`GetHistory()->histadd('search')`

Return type: `Number`

`histdel({history} [, {item}])`

`histdel()`

Clear `{history}`, i.e. delete all its entries. See `hist-names` for the possible values of `{history}`.

If the parameter `{item}` evaluates to a String, it is used as a

regular expression. All entries matching that expression will be removed from the history (if there are any). Upper/lowercase must match, unless "\c" is used `/\c`. If `{item}` evaluates to a Number, it will be interpreted as an index, see `:history-indexing`. The respective entry will be removed if it exists.

The result is TRUE for a successful operation, otherwise FALSE is returned.

Examples:

Clear expression register history:

```
:call histdel("expr")
```

Remove all entries starting with "\*" from the search history:

```
:call histdel("/", '^*')
```

The following three are equivalent:

```
:call histdel("search", histnr("search"))
```

```
:call histdel("search", -1)
```

```
:call histdel("search", '^' .. histget("search", -1) .. '$')
```

To delete the last search pattern and use the last-but-one for the "n" command and `'hlsearch'`:

```
:call histdel("search", -1)
```

```
:let @/ = histget("search", -1)
```

Can also be used as a `method` :

```
GetHistory()->histdel()
```

Return type: `Number`

`histget({history} [, {index}])` `histget()`

The result is a String, the entry with Number `{index}` from `{history}`. See `hist-names` for the possible values of `{history}`, and `:history-indexing` for `{index}`. If there is no such entry, an empty String is returned. When `{index}` is omitted, the most recent item from the history is used.

Examples:

Redo the second last search from history.

```
:execute '/' .. histget("search", -2)
```

Define an Ex command `":H {num}"` that supports re-execution of the `{num}`th entry from the output of `:history`.

```
:command -nargs=1 H execute histget("cmd", 0+<args>)
```

Can also be used as a `method` :

```
GetHistory()->histget()
```

Return type: `String`

histnr({history})

histnr()

The result is the Number of the current entry in {history}.  
See [hist-names](#) for the possible values of {history}.  
If an error occurred, -1 is returned.

Example:

```
:let inp_index = histnr("expr")
```

Can also be used as a [method](#) :  
[GetHistory\(\)](#)→[histnr\(\)](#)

Return type: [Number](#)

hlexists({name})

hlexists()

The result is a Number, which is TRUE if a highlight group called {name} exists. This is when the group has been defined in some way. Not necessarily when highlighting has been defined for it, it may also have been used for a syntax item.

[highlight\\_exists\(\)](#)

Obsolete name: [highlight\\_exists\(\)](#).

Can also be used as a [method](#) :  
[GetName\(\)](#)→[hlexists\(\)](#)

Return type: [Number](#)

hlget([[name] [, {resolve}]]])

hlget()

Returns a List of all the highlight group attributes. If the optional {name} is specified, then returns a List with only the attributes of the specified highlight group. Returns an empty List if the highlight group {name} is not present.

If the optional {resolve} argument is set to v:true and the highlight group {name} is linked to another group, then the link is resolved recursively and the attributes of the resolved highlight group are returned.

Each entry in the returned List is a Dictionary with the following items:

- cleared boolean flag, set to v:true if the highlight group attributes are cleared or not yet specified. See [highlight-clear](#) .
- cterm cterm attributes. See [highlight-cterm](#) .
- ctermbg cterm background color.  
See [highlight-ctermbg](#) .
- ctermfg cterm foreground color.  
See [highlight-ctermfg](#) .
- ctermul cterm underline color. See [highlight-ctermul](#) .
- default boolean flag, set to v:true if the highlight group link is a default link. See [highlight-default](#) .
- font highlight group font. See [highlight-font](#) .

gui       gui attributes. See [highlight-gui](#) .  
 guibg     gui background color. See [highlight-guibg](#) .  
 guifg     gui foreground color. See [highlight-guifg](#) .  
 guisp     gui special color. See [highlight-guisp](#) .  
 id        highlight group ID.  
 linksto   linked highlight group name.  
           See [:highlight-link](#) .  
 name      highlight group name. See [group-name](#) .  
 start     start terminal keycode. See [highlight-start](#) .  
 stop      stop terminal keycode. See [highlight-stop](#) .  
 term      term attributes. See [highlight-term](#) .

The **'term'**, **'cterm'** and **'gui'** items in the above Dictionary have a dictionary value with the following optional boolean items: **'bold'**, **'standout'**, **'underline'**, **'undercurl'**, **'italic'**, **'reverse'**, **'inverse'** and **'strikethrough'**.

Example(s):

```

:echo hlget()
:echo hlget('ModeMsg')
:echo hlget('Number', v:true)

```

Can also be used as a [method](#) :

```
GetName()->hlget()
```

Return type: list<dict<any>>

hlset({list})

[hlset\(\)](#)

Creates or modifies the attributes of a List of highlight groups. Each item in [{list}](#) is a dictionary containing the attributes of a highlight group. See [hlget\(\)](#) for the list of supported items in this dictionary.

In addition to the items described in [hlget\(\)](#) , the following additional items are supported in the dictionary:

          force               boolean flag to force the creation of  
                                   a link for an existing highlight group  
                                   with attributes.

The highlight group is identified using the **'name'** item and the **'id'** item (if supplied) is ignored. If a highlight group with a specified name doesn't exist, then it is created. Otherwise the attributes of an existing highlight group are modified.

If an empty dictionary value is used for the **'term'** or **'cterm'** or **'gui'** entries, then the corresponding attributes are cleared. If the **'cleared'** item is set to v:true, then all the attributes of the highlight group are cleared.

The **'linksto'** item can be used to link a highlight group to another highlight group. See [:highlight-link](#) .

Returns zero for success, -1 for failure.

Example(s):

```
" add bold attribute to the Visual highlight group
:call hlset([#{name: 'Visual',
 \ term: #{reverse: 1 , bold: 1}}])
:call hlset([#{name: 'Type', guifg: 'DarkGreen'}])
:let l = hlget()
:call hlset(l)
" clear the Search highlight group
:call hlset([#{name: 'Search', cleared: v:true}])
" clear the 'term' attributes for a highlight group
:call hlset([#{name: 'Title', term: {}}])
" create the MyHlg group linking it to DiffAdd
:call hlset([#{name: 'MyHlg', linksto: 'DiffAdd'}])
" remove the MyHlg group link
:call hlset([#{name: 'MyHlg', linksto: 'NONE'}])
" clear the attributes and a link
:call hlset([#{name: 'MyHlg', cleared: v:true,
 \ linksto: 'NONE'}])
```

Can also be used as a `method` :  
`GetAttrList()->hlset()`

Return type: `Number`

`hlID({name})`

`hlID()`

The result is a Number, which is the ID of the highlight group with name `{name}`. When the highlight group doesn't exist, zero is returned.

This can be used to retrieve information about the highlight group. For example, to get the background color of the "Comment" group:

```
:echo synIDattr(synIDtrans(hlID("Comment")), "bg")
highlightID()
```

Obsolete name: `highlightID()`.

Can also be used as a `method` :  
`GetName()->hlID()`

Return type: `Number`

`hostname()`

`hostname()`

The result is a String, which is the name of the machine on which Vim is currently running. Machine names greater than 256 characters long are truncated.

Return type: `String`

`iconv({string}, {from}, {to})`

`iconv()`

The result is a String, which is the text `{string}` converted

from encoding `{from}` to encoding `{to}`.  
When the conversion completely fails an empty string is returned. When some characters could not be converted they are replaced with "?".  
The encoding names are whatever the `iconv()` library function can accept, see `":!man 3 iconv"`.  
Most conversions require Vim to be compiled with the `+iconv` feature. Otherwise only UTF-8 to latin1 conversion and back can be done.  
This can be used to display messages with special characters, no matter what `'encoding'` is set to. Write the message in UTF-8 and use:

```
echo iconv(utf8_str, "utf-8", &enc)
```

**Note** that Vim uses UTF-8 for all Unicode encodings, conversion from/to UCS-2 is automatically changed to use UTF-8. You cannot use UCS-2 in a string anyway, because of the NUL bytes.

Can also be used as a `method` :

```
GetText()->iconv('latin1', 'utf-8')
```

Return type: `String`

`id({item})`

`id()`

The result is a unique `String` associated with the `{item}` and not with the `{item}`'s contents. It is only valid while the `{item}` exists and is referenced. It is valid only in the instance of vim that produces the result. The whole idea is that ``id({item})`` does not change if the contents of `{item}` changes. This is useful as a ``key`` for creating an identity dictionary, rather than one based on equals.

This operation does not reference `{item}` and there is no function to convert the ``id`` to the `{item}`. It may be useful to have a map of ``id`` to `{item}`. The following

```
var referenceMap: dict<any>
var id = item->id()
referenceMap[id] = item
```

prevents `{item}` from being garbage collected and provides a way to get the `{item}` from the ``id``.

`{item}` may be a `List`, `Dictionary`, `Object`, `Job`, `Channel` or `Blob`. If the item is not a permitted type, or it is a null value, then an empty `String` is returned.

Can also be used as a `method` :

```
GetItem()->id()
```

Return type: `String`

`indent({lnum})`

`indent()`

The result is a `Number`, which is indent of line `{lnum}` in the current buffer. The indent is counted in spaces, the value

of `'tabstop'` is relevant. `{lnum}` is used just like in `getline()` .  
When `{lnum}` is invalid -1 is returned. In `Vim9` script an error is given.

Can also be used as a `method` :  
`GetLnum()->indent()`

Return type: `Number`

`index({object}, {expr} [, {start} [, {ic}]])` `index()`  
Find `{expr}` in `{object}` and return its index. See `indexof()` for using a lambda to select the item.

If `{object}` is a `List` return the lowest index where the item has a value equal to `{expr}`. There is no automatic conversion, so the String "4" is different from the Number 4. And the number 4 is different from the Float 4.0. The value of `'ignorecase'` is not used here, case matters as indicated by the `{ic}` argument.

If `{object}` is `Blob` return the lowest index where the byte value is equal to `{expr}`.

If `{start}` is given then start looking at the item with index `{start}` (may be negative for an item relative to the end).

When `{ic}` is given and it is `TRUE` , ignore case. Otherwise case must match.

-1 is returned when `{expr}` is not found in `{object}`.

Example:

```
:let idx = index(words, "the")
:if index(numbers, 123) >= 0
```

Can also be used as a `method` :  
`GetObject()->index(what)`

Return type: `Number`

`indexof({object}, {expr} [, {opts}])` `indexof()`  
Returns the index of an item in `{object}` where `{expr}` is v:true. `{object}` must be a `List` or a `Blob` .

If `{object}` is a `List` , evaluate `{expr}` for each item in the List until the expression is v:true and return the index of this item.

If `{object}` is a `Blob` evaluate `{expr}` for each byte in the Blob until the expression is v:true and return the index of this byte.

`{expr}` must be a `string` or `Funcref` .

If `{expr}` is a `string` : If `{object}` is a `List` , inside `{expr} v:key` has the index of the current List item and `v:val` has the value of the item. If `{object}` is a `Blob` , inside `{expr} v:key` has the index of the current byte and `v:val` has the byte value.

If `{expr}` is a `Funcref` it must take two arguments:  
1. the key or the index of the current item.  
2. the value of the current item.

The function must return `TRUE` if the item is found and the search should stop.

The optional argument `{opts}` is a Dict and supports the following items:

`startidx` start evaluating `{expr}` at the item with this index; may be negative for an item relative to the end

Returns -1 when `{expr}` evaluates to `v:false` for all the items.

Example:

```
:let l = [#n: 10}, #{n: 20}, #{n: 30}]
:echo indexof(l, "v:val.n == 20")
:echo indexof(l, {i, v -> v.n == 30})
:echo indexof(l, "v:val.n == 20", #{startidx: 1})
```

Can also be used as a `method` :  
`mylist->indexof(expr)`

Return type: `Number`

`input({prompt} [, {text} [, {completion}]])` `input()`

The result is a String, which is whatever the user typed on the command-line. The `{prompt}` argument is either a prompt string, or a blank string (for no prompt). A `'\n'` can be used in the prompt to start a new line.

The highlighting set with `:echohl` is used for the prompt. The input is entered just like a command-line, with the same editing commands and mappings. There is a separate history for lines typed for `input()`.

Example:

```
:if input("Coffee or beer? ") == "beer"
: echo "Cheers!"
:endif
```

If the optional `{text}` argument is present and not empty, this is used for the default reply, as if the user typed this.

Example:

```
:let color = input("Color? ", "white")
```

The optional `{completion}` argument specifies the type of completion supported for the input. Without it completion is not performed. The supported completion types are the same as

that can be supplied to a user-defined command using the "-complete=" argument. Refer to `:command-completion` for more information. Example:

```
let fname = input("File: ", "", "file")
```

**NOTE:** This function must not be used in a startup file, for the versions that only run in GUI mode (e.g., the Win32 GUI).

**Note:** When `input()` is called from within a mapping it will consume remaining characters from that mapping, because a mapping is handled like the characters were typed.

Use `inputsave()` before `input()` and `inputrestore()` after `input()` to avoid that. Another solution is to avoid that further characters follow in the mapping, e.g., by using `:execute` or `:normal`.

Example with a mapping:

```
:nmap \x :call GetFoo()<CR>:exe "/" .. Foo<CR>
:function GetFoo()
: call inputsave()
: let g:Foo = input("enter search pattern: ")
: call inputrestore()
:endfunction
```

Can also be used as a `method` :

```
GetPrompt()->input()
```

Return type: `String`

`inputdialog({prompt} [, {text} [, {cancelreturn}]]])` `inputdialog()`

Like `input()`, but when the GUI is running and text dialogs are supported, a dialog window pops up to input the text.

Example:

```
:let n = inputdialog("value for shiftwidth", shiftwidth())
:if n != ""
: let &sw = n
:endif
```

When the dialog is cancelled `{cancelreturn}` is returned. When omitted an empty string is returned.

Hitting `<Enter>` works like pressing the OK button. Hitting `<Esc>` works like pressing the Cancel button.

**NOTE:** Command-line completion is not supported.

Can also be used as a `method` :

```
GetPrompt()->inputdialog()
```

Return type: `String`

`inputlist({textlist})` `inputlist()`

`{textlist}` must be a `List` of strings. This `List` is displayed, one string per line. The user will be prompted to enter a number, which is returned.

The user can also select an item by clicking on it with the

mouse, if the mouse is enabled in the command line ('mouse' is "a" or includes "c"). For the first string 0 is returned. When clicking above the first item a negative number is returned. When clicking on the prompt one more than the length of `{textlist}` is returned. Make sure `{textlist}` has less than 'lines' entries, otherwise it won't work. It's a good idea to put the entry number at the start of the string. And put a prompt in the first item. Example:

```
let color = inputlist(['Select color:', '1. red',
 \ '2. green', '3. blue'])
```

Can also be used as a `method` :  
`GetChoices()->inputlist()`

Return type: `Number`

`inputrestore()`

`inputrestore()`

Restore typeahead that was saved with a previous `inputsave()` . Should be called the same number of times `inputsave()` is called. Calling it more often is harmless though. Returns TRUE when there is nothing to restore, FALSE otherwise.

Return type: `Number`

`inputsave()`

`inputsave()`

Preserve typeahead (also from mappings) and clear it, so that a following prompt gets input from the user. Should be followed by a matching `inputrestore()` after the prompt. Can be used several times, in which case there must be just as many `inputrestore()` calls. Returns TRUE when out of memory, FALSE otherwise.

Return type: `Number`

`inputsecret({prompt} [, {text}])`

`inputsecret()`

This function acts much like the `input()` function with but two exceptions:

- a) the user's response will be displayed as a sequence of asterisks ("\*") thereby keeping the entry secret, and
- b) the user's response will not be recorded on the input `history` stack.

The result is a String, which is whatever the user actually typed on the command-line in response to the issued prompt. **NOTE:** Command-line completion is not supported.

Can also be used as a `method` :  
`GetPrompt()->inputsecret()`

Return type: `String`

`insert({object}, {item} [, {idx}])` `insert()`  
When `{object}` is a `List` or a `Blob` insert `{item}` at the start of it.

If `{idx}` is specified insert `{item}` before the item with index `{idx}`. If `{idx}` is zero it goes before the first item, just like omitting `{idx}`. A negative `{idx}` is also possible, see `list-index`. `-1` inserts just before the last item.

Returns the resulting `List` or `Blob`. Examples:

```
:let mylist = insert([2, 3, 5], 1)
:call insert(mylist, 4, -1)
:call insert(mylist, 6, len(mylist))
```

The last example can be done simpler with `add()`.

**Note** that when `{item}` is a `List` it is inserted as a single item. Use `extend()` to concatenate `Lists`.

Can also be used as a `method` :

```
mylist->insert(item)
```

Return type: `Number`

`instanceof({object}, {class})` `instanceof()` [E614](#) [E616](#) [E693](#)

The result is a `Number`, which is `TRUE` when the `{object}` argument is a direct or indirect instance of a `Class`, `Interface`, or class `:type` alias specified by `{class}`. If `{class}` is varargs, the function returns `TRUE` when `{object}` is an instance of any of the specified classes. Example:

```
instanceof(animal, Dog, Cat)
```

Can also be used as a `method` :

```
myobj->instanceof(mytype)
```

Return type: `Number`

`interrupt()` `interrupt()`

Interrupt script execution. It works more or less like the user typing **CTRL-C**, most commands won't execute and control returns to the user. This is useful to abort execution from lower down, e.g. in an autocommand. Example:

```
:function s:check_typoname(file)
: if fnamemodify(a:file, ':t') == '['
: echomsg 'Maybe typo'
: call interrupt()
: endif
:endfunction
:au BufWritePre * call s:check_typoname(expand('<amatch>'))
```

Return type: `void`

`invert({expr})` `invert()`  
Bitwise invert. The argument is converted to a number. A List, Dict or Float argument causes an error. Example:  
`:let bits = invert(bits)`  
Can also be used as a `method` :  
`:let bits = bits->invert()`  
  
Return type: `Number`

`isabsolutePath({path})` `isabsolutePath()`  
The result is a Number, which is `TRUE` when `{path}` is an absolute path.  
On Unix, a path is considered absolute when it starts with '/'.  
On MS-Windows, it is considered absolute when it starts with an optional drive prefix and is followed by a '\' or '/'. UNC paths are always absolute.  
Example:  
`echo isabsolutePath('/usr/share/') " 1`  
`echo isabsolutePath('./foobar') " 0`  
`echo isabsolutePath('C:\Windows') " 1`  
`echo isabsolutePath('foobar') " 0`  
`echo isabsolutePath('\\remote\file') " 1`  
  
Can also be used as a `method` :  
`GetName()->isabsolutePath()`  
  
Return type: `Number`

`isdirectory({directory})` `isdirectory()`  
The result is a Number, which is `TRUE` when a directory with the name `{directory}` exists. If `{directory}` doesn't exist, or isn't a directory, the result is `FALSE`. `{directory}` is any expression, which is used as a String.  
  
Can also be used as a `method` :  
`GetName()->isdirectory()`  
  
Return type: `Number`

`isinf({expr})` `isinf()`  
Return 1 if `{expr}` is a positive infinity, or -1 a negative infinity, otherwise 0.  
`:echo isinf(1.0 / 0.0)`  
`1`  
`:echo isinf(-1.0 / 0.0)`  
`-1`  
  
Can also be used as a `method` :  
`Compute()->isinf()`  
  
Return type: `Number`

`islocked({expr})` `islocked()` E786

The result is a Number, which is `TRUE` when `{expr}` is the name of a locked variable.

The string argument `{expr}` must be the name of a variable, `List` item or `Dictionary` entry, not the variable itself!

Example:

```
:let alist = [0, ['a', 'b'], 2, 3]
:lockvar 1 alist
:echo islocked('alist') " 1
:echo islocked('alist[1]') " 0
```

When `{expr}` is a variable that does not exist -1 is returned.

If `{expr}` uses a range, list or dict index that is out of range or does not exist you get an error message. Use `exists()` to check for existence.

In Vim9 script it does not work for local function variables.

Can also be used as a `method` :

```
GetName()->islocked()
```

Return type: `Number`

`isnan({expr})` `isnan()`

Return `TRUE` if `{expr}` is a float with value NaN.

```
echo isnan(0.0 / 0.0)
```

```
1
```

Can also be used as a `method` :

```
Compute()->isnan()
```

Return type: `Number`

`items({dict})` `items()`

Return a `List` with all the key-value pairs of `{dict}`. Each `List` item is a list with two items: the key of a `{dict}` entry and the value of this entry. The `List` is in arbitrary order. Also see `keys()` and `values()` .

Example:

```
for [key, value] in items(mydict)
 echo key .. ': ' .. value
endfor
```

A `List` or a `String` argument is also supported. In these cases, `items()` returns a `List` with the index and the value at the index.

Can also be used as a `method` :

```
mydict->items()
```

Return type: `list<list<any>>` or `list<any>`

job\_ functions are documented here: [job-functions-details](#)

`join({list} [, {sep}])` [join\(\)](#)  
Join the items in `{list}` together into one String.  
When `{sep}` is specified it is put in between the items. If `{sep}` is omitted a single space is used.  
**Note** that `{sep}` is not added at the end. You might want to add it there too:  
`let lines = join(mylist, "\n") .. "\n"`  
String items are used as-is. [Lists](#) and [Dictionaries](#) are converted into a string like with `string()` .  
The opposite function is `split()` .  
  
Can also be used as a [method](#) :  
`mylist->join()`  
  
Return type: [String](#)

`js_decode({string})` [js\\_decode\(\)](#)  
This is similar to `json_decode()` with these differences:  
- Object key names do not have to be in quotes.  
- Strings can be in single quotes.  
- Empty items in an array (between two commas) are allowed and result in `v:none` items.  
  
Can also be used as a [method](#) :  
`ReadObject()->js_decode()`  
  
Return type: any, depending on `{varname}`

`js_encode({expr})` [js\\_encode\(\)](#)  
This is similar to `json_encode()` with these differences:  
- Object key names are not in quotes.  
- `v:none` items in an array result in an empty item between commas.  
For example, the Vim object:  
`[1,v:none,{"one":1},v:none]`  
Will be encoded as:  
`[1,,{one:1},,]`  
While `json_encode()` would produce:  
`[1,null,{"one":1},null]`  
This encoding is valid for JavaScript. It is more efficient than JSON, especially when using an array with optional items.  
  
Can also be used as a [method](#) :  
`GetObject()->js_encode()`  
  
Return type: [String](#)

json\_decode({string})

json\_decode() E491

This parses a JSON formatted string and returns the equivalent in Vim values. See [json\\_encode\(\)](#) for the relation between JSON and Vim values.

The decoding is permissive:

- A trailing comma in an array and object is ignored, e.g. "[1, 2, ]" is the same as "[1, 2]".
- Integer keys are accepted in objects, e.g. {1:2} is the same as {"1":2}.
- More floating point numbers are recognized, e.g. "1." for "1.0", or "001.2" for "1.2". Special floating point values "Infinity", "-Infinity" and "NaN" (capitalization ignored) are accepted.
- Leading zeroes in integer numbers are ignored, e.g. "012" for "12" or "-012" for "-12".
- Capitalization is ignored in literal names null, true or false, e.g. "NULL" for "null", "True" for "true".
- Control characters U+0000 through U+001F which are not escaped in strings are accepted, e.g. " " (tab character in string) for "\t".
- An empty JSON expression or made of only spaces is accepted and results in v:none.
- Backslash in an invalid 2-character sequence escape is ignored, e.g. "\a" is decoded as "a".
- A correct surrogate pair in JSON strings should normally be a 12 character sequence such as "\uD834\uDD1E", but json\_decode() silently accepts truncated surrogate pairs such as "\uD834" or "\uD834\u"

E938

A duplicate key in an object, valid in rfc7159, is not accepted by json\_decode() as the result must be a valid Vim type, e.g. this fails: {"a":"b", "a":"c"}

Can also be used as a [method](#) :

[ReadObject\(\)->json\\_decode\(\)](#)

Return type: any, depending on {varname}

json\_encode({expr})

json\_encode()

Encode {expr} as JSON and return this as a string.

The encoding is specified in:

<https://tools.ietf.org/html/rfc7159.html>

Vim values are converted as follows: E1161

Number	decimal number
Float	floating point number
Float nan	"NaN"
Float inf	"Infinity"
Float -inf	"-Infinity"
String	in double quotes (possibly null)
Funcref	not possible, error
List	as an array (possibly null); when used recursively: []

<code>Dict</code>	as an object (possibly null); when used recursively: <code>{}</code>
<code>Blob</code>	as an array of the individual bytes
<code>v:false</code>	"false"
<code>v:true</code>	"true"
<code>v:none</code>	"null"
<code>v:null</code>	"null"

**Note** that NaN and Infinity are passed on as values. This is missing in the JSON standard, but several implementations do allow it. If not then you will get an error. If a string contains an illegal character then the replacement character `0xffffd` is used.

Can also be used as a `method` :  
`GetObject()->json_encode()`

Return type: `String`

`keys({dict})`

`keys()`

Return a `List` with all the keys of `{dict}`. The `List` is in arbitrary order. Also see `items()` and `values()` .

Can also be used as a `method` :  
`mydict->keys()`

Return type: `list<string>`

`keytrans({string})`

`keytrans()`

Turn the internal byte representation of keys into a form that can be used for `:map` . E.g.

```
:let xx = "\<C-Home>"
:echo keytrans(xx)
<C-Home>
```

Can also be used as a `method` :  
`"\<C-Home>"->keytrans()`

Return type: `String`

`len({expr})`

`len()` **E701**

The result is a Number, which is the length of the argument. When `{expr}` is a String or a Number the length in bytes is used, as with `strlen()` .

When `{expr}` is a `List` the number of items in the `List` is returned.

When `{expr}` is a `Blob` the number of bytes is returned.

When `{expr}` is a `Dictionary` the number of entries in the `Dictionary` is returned.

When `{expr}` is an `Object` , invokes the `len()` method in the object (if present) to get the length ( `object-len()` ).

Otherwise returns zero.

Can also be used as a `method` :  
`mylist->len()`

Return type: `Number`

`libcall({libname}, {funcname}, {argument})` `libcall()` E364 E368  
Call function `{funcname}` in the run-time library `{libname}` with single argument `{argument}`. This is useful to call functions in a library that you especially made to be used with Vim. Since only one argument is possible, calling standard library functions is rather limited. The result is the String returned by the function. If the function returns NULL, this will appear as an empty string "" to Vim. If the function returns a number, use `libcallnr()`! If `{argument}` is a number, it is passed to the function as an int; if `{argument}` is a string, it is passed as a null-terminated string. This function will fail in `restricted-mode` .

`libcall()` allows you to write your own 'plug-in' extensions to Vim without having to recompile the program. It is NOT a means to call system functions! If you try to do so Vim will very probably crash.

For Win32, the functions you write must be placed in a DLL and use the normal C calling convention (NOT Pascal which is used in Windows System DLLs). The function must take exactly one parameter, either a character pointer or a long integer, and must return a character pointer or NULL. The character pointer returned must point to memory that will remain valid after the function has returned (e.g. in static data in the DLL). If it points to allocated memory, that memory will leak away. Using a static buffer in the function should work, it's then freed when the DLL is unloaded.

WARNING: If the function returns a non-valid pointer, Vim may crash! This also happens if the function returns a number, because Vim thinks it's a pointer. For Win32 systems, `{libname}` should be the filename of the DLL without the ".DLL" suffix. A full path is only required if the DLL is not in the usual places. For Unix: When compiling your own plugins, remember that the object code must be compiled as position-independent ('PIC'). {only in Win32 and some Unix versions, when the `+libcall` feature is present}

Examples:

```
:echo libcall("libc.so", "getenv", "HOME")
```

Can also be used as a `method` , the base is passed as the

third argument:

```
GetValue()->libcall("libc.so", "getenv")
```

`libcallnr()`

`libcallnr({libname}, {funcname}, {argument})`

Just like `libcall()` , but used for a function that returns an int instead of a string.

{only in Win32 on some Unix versions, when the `+libcall` feature is present}

Examples:

```
:echo libcallnr("/usr/lib/libc.so", "getpid", "")
:call libcallnr("libc.so", "printf", "Hello World!\n")
:call libcallnr("libc.so", "sleep", 10)
```

Can also be used as a `method` , the base is passed as the third argument:

```
GetValue()->libcallnr("libc.so", "printf")
```

Return type: `String`

`line({expr} [, {winid}])`

`line()`

The result is a Number, which is the line number of the file position given with `{expr}`. The `{expr}` argument is a string. See `getpos()` for accepted positions.

To get the column number use `col()` . To get both use `getpos()` .

With the optional `{winid}` argument the values are obtained for that window instead of the current window.

Returns 0 for invalid values of `{expr}` and `{winid}`.

Examples:

```
line(".") line number of the cursor
line(".", winid) idem, in window "winid"
line("t") line number of mark t
line("' " .. marker) line number of mark marker
```

To jump to the last known position when opening a file see `last-position-jump` .

Can also be used as a `method` :

```
GetValue()->line()
```

Return type: `Number`

`line2byte({lnum})`

`line2byte()`

Return the byte count from the start of the buffer for line `{lnum}`. This includes the end-of-line character, depending on the `'fileformat'` option for the current buffer. The first line returns 1. `'encoding'` matters, `'fileencoding'` is ignored.

This can also be used to get the byte count for the line just below the last line:

```
line2byte(line("$") + 1)
```

This is the buffer size plus one. If `'fileencoding'` is empty it is the file size plus one. `{lnum}` is used like with `getline()`. When `{lnum}` is invalid, or the `+byte_offset` feature has been disabled at compile time, -1 is returned. Also see `byte2line()`, `go` and `:goto`.

Can also be used as a `method` :

```
GetLnum()->line2byte()
```

Return type: `Number`

`lispindent({lnum})` `lispindent()`

Get the amount of indent for line `{lnum}` according the lisp indenting rules, as with `'lisp'`. The indent is counted in spaces, the value of `'tabstop'` is relevant. `{lnum}` is used just like in `getline()`. When `{lnum}` is invalid -1 is returned. In `Vim9` script an error is given.

Can also be used as a `method` :

```
GetLnum()->lispindent()
```

Return type: `Number`

`list2blob({list})` `list2blob()`

Return a Blob concatenating all the number values in `{list}`.  
Examples:

```
list2blob([1, 2, 3, 4]) returns 0z01020304
```

```
list2blob([]) returns 0z
```

Returns an empty Blob on error. If one of the numbers is negative or more than 255 error `E1239` is given.

`blob2list()` does the opposite.

Can also be used as a `method` :

```
GetList()->list2blob()
```

Return type: `Blob`

`list2str({list} [, {utf8}])` `list2str()`

Convert each number in `{list}` to a character string and concatenates them all. Examples:

```
list2str([32]) returns " "
```

```
list2str([65, 66, 67]) returns "ABC"
```

The same can be done (slowly) with:

```
join(map(list, {nr, val -> nr2char(val)}), '')
```

`str2list()` does the opposite.

When `{utf8}` is omitted or zero, the current `'encoding'` is used.  
When `{utf8}` is TRUE, always return UTF-8 characters.  
With UTF-8 composing characters work as expected:  
`list2str([97, 769])` returns `"á"`

Returns an empty string on error.

Can also be used as a `method` :  
`GetList()->list2str()`

Return type: `String`

`listener_add({callback} [, {buf}])` `listener_add()`  
Add a callback function that will be invoked when changes have been made to buffer `{buf}`.  
`{buf}` refers to a buffer name or number. For the accepted values, see `bufname()` . When `{buf}` is omitted the current buffer is used.  
Returns a unique ID that can be passed to `listener_remove()` .

The `{callback}` is invoked with five arguments:

<code>bufnr</code>	the buffer that was changed
<code>start</code>	first changed line number
<code>end</code>	first line number below the change
<code>added</code>	number of lines added, negative if lines were deleted
<code>changes</code>	a List of items with details about the changes

Example:

```
func Listener(bufnr, start, end, added, changes)
 echo 'lines ' .. a:start .. ' until ' .. a:end .. ' changed'
endfunc
call listener_add('Listener', bufnr)
```

The List cannot be changed. Each item in "changes" is a dictionary with these entries:

<code>lnum</code>	the first line number of the change
<code>end</code>	the first line below the change
<code>added</code>	number of lines added; negative if lines were deleted
<code>col</code>	first column in "lnum" that was affected by the change; one if unknown or the whole line was affected; this is a byte index, first character has a value of one.

When lines are inserted (not when a line is split, e.g. by typing CR in Insert mode) the values are:

<code>lnum</code>	line above which the new line is added
<code>end</code>	equal to "lnum"
<code>added</code>	number of lines inserted
<code>col</code>	1

When lines are deleted the values are:

<code>lnum</code>	the first deleted line
<code>end</code>	the line below the first deleted line, before

```

 the deletion was done
 added negative, number of lines deleted
 col 1
When lines are changed:
 lnum the first changed line
 end the line below the last changed line
 added 0
 col first column with a change or 1

```

The entries are in the order the changes were made, thus the most recent change is at the end. The line numbers are valid when the callback is invoked, but later changes may make them invalid, thus keeping a copy for later might not work.

The `{callback}` is invoked just before the screen is updated, when `listener_flush()` is called or when a change is being made that changes the line count in a way it causes a line number in the list of changes to become invalid.

The `{callback}` is invoked with the text locked, see `textlock`. If you do need to make changes to the buffer, use a timer to do this later `timer_start()`.

The `{callback}` is not invoked when the buffer is first loaded. Use the `BufReadPost` autocmd event to handle the initial text of a buffer.

The `{callback}` is also not invoked when the buffer is unloaded, use the `BufUnload` autocmd event for that.

Returns zero if `{callback}` or `{buf}` is invalid.

Can also be used as a `method`, the base is passed as the second argument:

```
GetBuffer()->listener_add(callback)
```

Return type: `Number`

```
listener_flush([{buf}]) listener_flush()
Invoke listener callbacks for buffer {buf}. If there are no pending changes then no callbacks are invoked.
```

`{buf}` refers to a buffer name or number. For the accepted values, see `bufname()`. When `{buf}` is omitted the current buffer is used.

Can also be used as a `method` :

```
GetBuffer()->listener_flush()
```

Return type: `Number`

```
listener_remove({id}) listener_remove()
Remove a listener previously added with listener_add().
```

Returns FALSE when {id} could not be found, TRUE when {id} was removed.

Can also be used as a `method` :

```
GetListenerId()->listener_remove()
```

Return type: `Number`

`localtime()`

`localtime()`

Return the current time, measured as seconds since 1st Jan 1970. See also `strftime()` , `strptime()` and `getftime()` .

Return type: `Number`

`log({expr})`

`log()`

Return the natural logarithm (base e) of {expr} as a `Float` . {expr} must evaluate to a `Float` or a `Number` in the range (0, inf].

Returns 0.0 if {expr} is not a `Float` or a `Number` .

Examples:

```
:echo log(10)
2.302585
:echo log(exp(5))
5.0
```

Can also be used as a `method` :

```
Compute()->log()
```

Return type: `Float`

`log10({expr})`

`log10()`

Return the logarithm of Float {expr} to base 10 as a `Float` . {expr} must evaluate to a `Float` or a `Number` .

Returns 0.0 if {expr} is not a `Float` or a `Number` .

Examples:

```
:echo log10(1000)
3.0
:echo log10(0.01)
-2.0
```

Can also be used as a `method` :

```
Compute()->log10()
```

Return type: `Float`

`luaeval({expr} [, {expr}])`

`luaeval()`

Evaluate Lua expression {expr} and return its result converted to Vim data structures. Second {expr} may hold additional argument accessible as `_A` inside first {expr}.

Strings are returned as they are.

Boolean objects are converted to numbers.  
Numbers are converted to `Float` values.  
Dictionaries and lists obtained by `vim.eval()` are returned as-is.  
Other objects are returned as zero without any errors.  
See `lua-luaeval` for more details.  
**Note** that in a `:def` function local variables are not visible to `{expr}`.

Can also be used as a `method` :  
`GetExpr()->luaeval()`

Return type: any, depending on `{expr}`

`{only available when compiled with the |+lua| feature}`

`map({expr1}, {expr2})` `map()`  
`{expr1}` must be a `List`, `String`, `Blob` or `Dictionary`.  
When `{expr1}` is a `List` or `Dictionary`, replace each item in `{expr1}` with the result of evaluating `{expr2}`.  
For a `Blob` each byte is replaced.  
For a `String`, each character, including composing characters, is replaced.  
If the item type changes you may want to use `mapnew()` to create a new `List` or `Dictionary`. This is required when using Vim9 script.

`{expr2}` must be a `String` or `Funcref`.

If `{expr2}` is a `String`, inside `{expr2}` `v:val` has the value of the current item. For a `Dictionary` `v:key` has the key of the current item and for a `List` `v:key` has the index of the current item. For a `Blob` `v:key` has the index of the current byte. For a `String` `v:key` has the index of the current character.

Example:

```
:call map(mylist, '> " .. v:val .. " <")
```

This puts "> " before and " <" after each item in "mylist".

**Note** that `{expr2}` is the result of an expression and is then used as an expression again. Often it is good to use a `literal-string` to avoid having to double backslashes. You still have to double ' quotes

If `{expr2}` is a `Funcref` it is called with two arguments:

1. The key or the index of the current item.
2. the value of the current item.

With a legacy script lambda you don't get an error if it only accepts one argument, but with a Vim9 lambda you get "E1106: One argument too many", the number of arguments must match.

The function must return the new value of the item. Example that changes each value by "key-value":

```

func KeyValue(key, val)
 return a:key .. '-' .. a:val
endfunc
call map(myDict, function('KeyValue'))

```

It is shorter when using a `lambda` :

```
call map(myDict, {key, val -> key .. '-' .. val})
```

If you do not use "val" you can leave it out:

```
call map(myDict, {key -> 'item: ' .. key})
```

If you do not use "key" you can use a short name:

```
call map(myDict, {_, val -> 'item: ' .. val})
```

The operation is done in-place for a `List` and `Dictionary` .

If you want it to remain unmodified make a copy first:

```
:let tlist = map(copy(mylist), ' v:val .. "\t"')
```

Returns `{expr1}`, the `List` or `Dictionary` that was filtered, or a new `Blob` or `String` .

When an error is encountered while evaluating `{expr2}` no further items in `{expr1}` are processed.

When `{expr2}` is a Funcref errors inside a function are ignored, unless it was defined with the "abort" flag.

Can also be used as a `method` :

```
mylist->map(expr2)
```

Return type: `String` , `Blob` , `list<{type}>` or `dict<{type}>` depending on `{expr1}`

`maparg({name} [, {mode} [, {abbr} [, {dict}]]])` `maparg()`

When `{dict}` is omitted or zero: Return the rhs of mapping `{name}` in mode `{mode}`. The returned String has special characters translated like in the output of the ":map" command listing. When `{dict}` is TRUE a dictionary is returned, see below. To get a list of all mappings see `maplist()` .

When there is no mapping for `{name}`, an empty String is returned if `{dict}` is FALSE, otherwise returns an empty Dict. When the mapping for `{name}` is empty, then "<Nop>" is returned.

The `{name}` can have special key names, like in the ":map" command.

`{mode}` can be one of these strings:

```

"n" Normal
"v" Visual (including Select)
"o" Operator-pending
"i" Insert
"c" Cmd-line
"s" Select
"x" Visual
"l" langmap language-mapping
"t" Terminal-Job

```

"" Normal, Visual and Operator-pending  
When `{mode}` is omitted, the modes for "" are used.

When `{abbr}` is there and it is `TRUE` use abbreviations instead of mappings.

When `{dict}` is there and it is `TRUE` return a dictionary containing all the information of the mapping with the following items:

`mapping-dict`

- "lhs" The `{lhs}` of the mapping as it would be typed
- "lhsraw" The `{lhs}` of the mapping as raw bytes
- "lhsrawalt" The `{lhs}` of the mapping as raw bytes, alternate form, only present when it differs from "lhsraw"
- "rhs" The `{rhs}` of the mapping as typed.
- "silent" 1 for a `:map-silent` mapping, else 0.
- "noremap" 1 if the `{rhs}` of the mapping is not remappable.
- "script" 1 if mapping was defined with `<script>`.
- "expr" 1 for an expression mapping ( `:map-<expr>` ).
- "buffer" 1 for a buffer local mapping ( `:map-local` ).
- "mode" Modes for which the mapping is defined. In addition to the modes mentioned above, these characters will be used:
  - " " Normal, Visual and Operator-pending
  - "! " Insert and Commandline mode ( `mapmode-ic` )
- "sid" The script local ID, used for `<sid>` mappings ( `<SID>` ). Negative for special contexts.
- "scriptversion" The version of the script. 999999 for `Vim9` script.
- "lnum" The line number in "sid", zero if unknown.
- "nowait" Do not wait for other, longer mappings. ( `:map-<nowait>` ).
- "abbr" True if this is an abbreviation `abbreviations` .
- "mode\_bits" Vim's internal binary representation of "mode". `mapset()` ignores this; only "mode" is used. See `maplist()` for usage examples. The values are from `src/vim.h` and may change in the future.

The dictionary can be used to restore a mapping with `mapset()` .

The mappings local to the current buffer are checked first, then the global mappings.

This function can be used to map a key even when it's already mapped, and have it do the original mapping too. Sketch:

```
exe 'nnoremap <Tab> ==' .. maparg('<Tab>', 'n')
```

Can also be used as a `method` :

```
GetKey()->maparg('n')
```

Return type: `String` or `dict<any>` depending on `{dict}`

`mapcheck({name} [, {mode} [, {abbr}]])`

`mapcheck()`

Check if there is a mapping that matches with `{name}` in mode `{mode}`. See `maparg()` for `{mode}` and special names in `{name}`.

When `{abbr}` is there and it is `TRUE` use abbreviations instead of mappings.

A match happens with a mapping that starts with `{name}` and with a mapping which is equal to the start of `{name}`.

	matches mapping	"a"	"ab"	"abc"
<code>mapcheck("a")</code>	yes	yes	yes	yes
<code>mapcheck("abc")</code>	yes	yes	yes	yes
<code>mapcheck("ax")</code>	yes	no	no	no
<code>mapcheck("b")</code>	no	no	no	no

The difference with `maparg()` is that `mapcheck()` finds a mapping that matches with `{name}`, while `maparg()` only finds a mapping for `{name}` exactly.

When there is no mapping that starts with `{name}`, an empty String is returned. If there is one, the RHS of that mapping is returned. If there are several mappings that start with `{name}`, the RHS of one of them is returned. This will be "`<Nop>`" if the RHS is empty.

The mappings local to the current buffer are checked first, then the global mappings.

This function can be used to check if a mapping can be added without being ambiguous. Example:

```
:if mapcheck("_vv") == ""
: map _vv :set guifont=7x13<CR>
:endif
```

This avoids adding the `"_vv"` mapping when there already is a mapping for `"_v"` or for `"_vvv"`.

Can also be used as a `method` :

```
GetKey()->mapcheck('n')
```

Return type: `String`

`maplist([{abbr}])`

`maplist()`

Returns a `List` of all mappings. Each List item is a `Dict`, the same as what is returned by `maparg()`, see `mapping-dict`. When `{abbr}` is there and it is `TRUE` use abbreviations instead of mappings.

Example to show all mappings with 'MultiMatch' in rhs:

```
vim9script
echo maplist()->filter(
 (_, m) => match(m.rhs, 'MultiMatch') >= 0)
```

It can be tricky to find mappings for particular `:map-modes`. `mapping-dict`'s `"mode_bits"` can simplify this. For example, the `mode_bits` for Normal, Insert or Command-line modes are `0x19`. To find all the mappings available in those modes you can do:

```
vim9script
```

```

var saved_maps = []
for m in maplist()
 if and(m.mode_bits, 0x19) != 0
 saved_maps->add(m)
 endif
endfor
echo saved_maps->mapnew((_, m) => m.lhs)

```

The values of the mode\_bits are defined in Vim's src/vim.h file and they can be discovered at runtime using `:map-commands` and "maplist()". Example:

```

vim9script
omap xyzyy <Nop>
var op_bit = maplist()->filter(
 (_, m) => m.lhs == 'xyzyy')[0].mode_bits
ounmap xyzyy
echo printf("Operator-pending mode bit: 0x%x", op_bit)

```

Return type: list<dict<any>>

`mapnew({expr1}, {expr2})` mapnew()  
 Like `map()` but instead of replacing items in `{expr1}` a new List or Dictionary is created and returned. `{expr1}` remains unchanged. Items can still be changed by `{expr2}`, if you don't want that use `deepcopy()` first.

Return type: `String` , `Blob` , list<{type}> or dict<{type}> depending on `{expr1}`

`mapset({mode}, {abbr}, {dict})` mapset()  
`mapset({dict})`

Restore a mapping from a dictionary, possibly returned by `maparg()` or `maplist()` . A buffer mapping, when `dict.buffer` is true, is set on the current buffer; it is up to the caller to ensure that the intended buffer is the current buffer. This feature allows copying mappings from one buffer to another. The `dict.mode` value may restore a single mapping that covers more than one mode, like with mode values of `!'`, `' '`, `'nox'`, or `'v'`. [E1276](#)

In the first form, `{mode}` and `{abbr}` should be the same as for the call to `maparg()` . [E460](#)  
`{mode}` is used to define the mode in which the mapping is set, not the "mode" entry in `{dict}`.

Example for saving and restoring a mapping:

```

let save_map = maparg('K', 'n', 0, 1)
nnoremap K somethingelse
...
call mapset('n', 0, save_map)

```

**Note** that if you are going to replace a map in several modes, e.g. with ``:map!``, you need to save/restore the mapping for all of them, when they might differ.

In the second form, with `{dict}` as the only argument, `mode` and `abbr` are taken from the dict.

Example:

```
vim9script
var save_maps = maplist()->filter(
 (_, m) => m.lhs == 'K')
nnoremap K somethingelse
cnoremap K somethingelse2
...
unmap K
for d in save_maps
 mapset(d)
endfor
```

Return type: `Number`

`match({expr}, {pat} [, {start} [, {count}]]])` `match()`

When `{expr}` is a `List` then this returns the index of the first item where `{pat}` matches. Each item is used as a String, `Lists` and `Dictionaries` are used as echoed.

Otherwise, `{expr}` is used as a String. The result is a `Number`, which gives the index (byte offset) in `{expr}` where `{pat}` matches.

A match at the first character or `List` item returns zero. If there is no match -1 is returned.

For getting submatches see `matchlist()` .

Example:

```
:echo match("testing", "ing") " results in 4
:echo match([1, 'x'], '\a') " results in 1
```

See `string-match` for how `{pat}` is used.

`strpbrk()`

Vim doesn't have a `strpbrk()` function. But you can do:

```
:let sepidx = match(line, '[.,;: \t]')
```

`strcasestr()`

Vim doesn't have a `strcasestr()` function. But you can add `"\c"` to the pattern to ignore case:

```
:let idx = match(haystack, '\cneedle')
```

If `{start}` is given, the search starts from byte index `{start}` in a String or item `{start}` in a `List` .

The result, however, is still the index counted from the first character/item. Example:

```
:echo match("testing", "ing", 2)
```

result is again "4".

```
:echo match("testing", "ing", 4)
```

result is again "4".

```
:echo match("testing", "t", 2)
```

result is "3".

For a String, if `{start}` > 0 then it is like the string starts `{start}` bytes later, thus `"^"` will match at `{start}`. Except

when `{count}` is given, then it's like matches before the `{start}` byte are ignored (this is a bit complicated to keep it backwards compatible).

For a String, if `{start} < 0`, it will be set to 0. For a list the index is counted from the end.

If `{start}` is out of range (`{start} > strlen({expr})` for a String or `{start} > len({expr})` for a `List`) -1 is returned.

When `{count}` is given use the `{count}`'th match. When a match is found in a String the search for the next one starts one character further. Thus this example results in 1:

```
echo match("testing", "..", 0, 2)
```

In a `List` the search continues in the next item.

**Note** that when `{count}` is added the way `{start}` works changes, see above.

#### match-pattern

See `pattern` for the patterns that are accepted.

The `'ignorecase'` option is used to set the ignore-caseness of the pattern. `'smartcase'` is NOT used. The matching is always done like `'magic'` is set and `'coptions'` is empty.

**Note** that a match at the start is preferred, thus when the pattern is using "\*" (any number of matches) it tends to find zero matches at the start instead of a number of matches further down in the text.

Can also be used as a `method` :

```
GetText()->match('word')
```

```
GetList()->match('word')
```

Return type: `Number`

`matchadd({group}, {pattern} [, {priority} [, {id} [, {dict}]]])` E290 E798 E799 E801 E957

Defines a pattern to be highlighted in the current window (a "match"). It will be highlighted with `{group}`. Returns an identification number (ID), which can be used to delete the match using `matchdelete()`. The ID is bound to the window. Matching is case sensitive and magic, unless case sensitivity or magicness are explicitly overridden in `{pattern}`. The `'magic'`, `'smartcase'` and `'ignorecase'` options are not used. The "Conceal" value is special, it causes the match to be concealed.

The optional `{priority}` argument assigns a priority to the match. A match with a high priority will have its highlighting overrule that of a match with a lower priority. A priority is specified as an integer (negative numbers are no exception). If the `{priority}` argument is not specified, the default priority is 10. The priority of `'hlsearch'` is zero, hence all matches with a priority greater than zero will overrule it. Syntax highlighting (see `'syntax'`) is a separate mechanism, and regardless of the chosen priority a match will

always overrule syntax highlighting.

The optional `{id}` argument allows the request for a specific match ID. If a specified ID is already taken, an error message will appear and the match will not be added. An ID is specified as a positive integer (zero excluded). IDs 1, 2 and 3 are reserved for `:match`, `:2match` and `:3match`, respectively. 3 is reserved for use by the `matchparen` plugin.

If the `{id}` argument is not specified or `-1`, `matchadd()` automatically chooses a free ID, which is at least 1000.

The optional `{dict}` argument allows for further custom values. Currently this is used to specify a match specific conceal character that will be shown for `hl-Conceal` highlighted matches. The dict can have the following members:

<code>conceal</code>	Special character to show instead of the match (only for <code>hl-Conceal</code> highlighted matches, see <code>:syn-cchar</code> )
<code>window</code>	Instead of the current window use the window with this number or window ID.

The number of matches is not limited, as it is the case with the `:match` commands.

Returns `-1` on error.

Example:

```
:highlight MyGroup ctermbg=green guibg=green
:let m = matchadd("MyGroup", "TODO")
```

Deletion of the pattern:

```
:call matchdelete(m)
```

A list of matches defined by `matchadd()` and `:match` are available from `getmatches()`. All matches can be deleted in one operation by `clearmatches()`.

Can also be used as a `method`:

```
GetGroup()->matchadd('TODO')
```

Return type: `Number`

`matchaddpos({group}, {pos} [, {priority} [, {id} [, {dict}]]])`  
Same as `matchadd()`, but requires a list of positions `{pos}` instead of a pattern. This command is faster than `matchadd()` because it does not handle regular expressions and it sets buffer line boundaries to redraw screen. It is supposed to be used when fast match additions and deletions are required, for example to highlight matching parentheses.

`{pos}` is a list of positions. Each position can be one of

these:

- A number. This whole line will be highlighted. The first line has number 1.
- A list with one number, e.g., [23]. The whole line with this number will be highlighted.
- A list with two numbers, e.g., [23, 11]. The first number is the line number, the second one is the column number (first column is 1, the value must correspond to the byte index as `col()` would return). The character at this position will be highlighted.
- A list with three numbers, e.g., [23, 11, 3]. As above, but the third number gives the length of the highlight in bytes.

Returns -1 on error.

Example:

```
:highlight MyGroup ctermbg=green guibg=green
:let m = matchaddpos("MyGroup", [[23, 24], 34])
```

Deletion of the pattern:

```
:call matchdelete(m)
```

Matches added by `matchaddpos()` are returned by `getmatches()` .

Can also be used as a `method` :

```
GetGroup()->matchaddpos([23, 11])
```

Return type: `Number`

`matcharg({nr})`

`matcharg()`

Selects the `{nr}` match item, as set with a `:match` , `:2match` or `:3match` command.

Return a `List` with two elements:

The name of the highlight group used  
The pattern used.

When `{nr}` is not 1, 2 or 3 returns an empty `List` .

When there is no match item set returns `['', '']`.

This is useful to save and restore a `:match` .

Highlighting matches using the `:match` commands are limited to three matches. `matchadd()` does not have this limitation.

Can also be used as a `method` :

```
GetMatch()->matcharg()
```

Return type: `list<string>`

`matchbufline({buf}, {pat}, {lnum}, {end}, [, {dict}])`

`matchbufline()`

Returns the `List` of matches in lines from `{lnum}` to `{end}` in buffer `{buf}` where `{pat}` matches.

`{lnum}` and `{end}` can either be a line number or the string "\$" to refer to the last line in `{buf}`.

The `{dict}` argument supports following items:  
submatches include submatch information ( `/\()` )

For each match, a `Dict` with the following items is returned:  
byteidx starting byte index of the match  
lnum line number where there is a match  
text matched string

**Note** that there can be multiple matches in a single line.

This function works only for loaded buffers. First call `bufload()` if needed.

See `match-pattern` for information about the effect of some option settings on the pattern.

When `{buf}` is not a valid buffer, the buffer is not loaded or `{lnum}` or `{end}` is not valid then an error is given and an empty `List` is returned.

Examples:

```
" Assuming line 3 in buffer 5 contains "a"
:echo matchbufline(5, '\<k\>', 3, 3)
[{'lnum': 3, 'byteidx': 0, 'text': 'a'}]
" Assuming line 4 in buffer 10 contains "tik tok"
:echo matchbufline(10, '\<k\>', 1, 4)
[{'lnum': 4, 'byteidx': 0, 'text': 'tik'}, {'lnum': 4, 'byteidx': 4, 'text': 'tok'}]
```

If `{submatch}` is present and is `v:true`, then submatches like `"\1"`, `"\2"`, etc. are also returned. Example:

```
" Assuming line 2 in buffer 2 contains "acd"
:echo matchbufline(2, '\(a)\?\(b)\?\(c)\?\(.*\)', 2, 2
\ {'submatches': v:true})
[{'lnum': 2, 'byteidx': 0, 'text': 'acd', 'submatches': ['a', '', 'c', 'd']}]
```

The "submatches" List always contains 9 items. If a submatch is not found, then an empty string is returned for that submatch.

Can also be used as a `method` :

```
GetBuffer()->matchbufline('mypat', 1, '$')
```

Return type: `list<dict<any>>` or `list<any>`

`matchdelete({id} [, {win}])` `matchdelete()` E802 E803  
Deletes a match with ID `{id}` previously defined by `matchadd()` or one of the `:match` commands. Returns 0 if successful, otherwise -1. See example for `matchadd()` . All matches can be deleted in one operation by `clearmatches()` .  
If `{win}` is specified, use the window with this number or window ID instead of the current window.

Can also be used as a `method` :

```
GetMatch()->matchdelete()
```

Return type: `Number`

`matchend({expr}, {pat} [, {start} [, {count}]])` `matchend()`

Same as `match()` , but return the index of first character after the match. Example:

```
:echo matchend("testing", "ing")
results in "7".
```

`strspn()` `strcspn()`

Vim doesn't have a `strspn()` or `strcspn()` function, but you can do it with `matchend()`:

```
:let span = matchend(line, '[a-zA-Z]')
:let span = matchend(line, '^[a-zA-Z]')
```

Except that `-1` is returned when there are no matches.

The `{start}`, if given, has the same meaning as for `match()` .

```
:echo matchend("testing", "ing", 2)
results in "7".
```

```
:echo matchend("testing", "ing", 5)
result is "-1".
```

When `{expr}` is a `List` the result is equal to `match()` .

Can also be used as a `method` :

```
GetText()->matchend('word')
```

Return type: `Number`

`matchfuzzy({list}, {str} [, {dict}])` `matchfuzzy()`

If `{list}` is a list of strings, then returns a `List` with all the strings in `{list}` that fuzzy match `{str}`. The strings in the returned list are sorted based on the matching score.

The optional `{dict}` argument always supports the following items:

<code>matchseq</code>	When this item is present return only matches that contain the characters in <code>{str}</code> in the given sequence.
<code>limit</code>	Maximum number of matches in <code>{list}</code> to be returned. Zero means no limit.

If `{list}` is a list of dictionaries, then the optional `{dict}` argument supports the following additional items:

<code>key</code>	Key of the item which is fuzzy matched against <code>{str}</code> . The value of this item should be a string.
<code>text_cb</code>	<code>Funcref</code> that will be called for every item in <code>{list}</code> to get the text for fuzzy matching. This should accept a dictionary item as the argument and return the text for that item to use for fuzzy matching.

`{str}` is treated as a literal string and regular expression

matching is NOT supported. The maximum supported `{str}` length is 256.

When `{str}` has multiple words each separated by white space, then the list of strings that have all the words is returned.

If there are no matching strings or there is an error, then an empty list is returned. If length of `{str}` is greater than 256, then returns an empty list.

When `{limit}` is given, `matchfuzzy()` will find up to this number of matches in `{list}` and return them in sorted order.

Refer to [fuzzy-matching](#) for more information about fuzzy matching strings.

Example:

```
:echo matchfuzzy(["clay", "crow"], "cay")
results in ["clay"].
:echo getbufinfo()->map({_, v -> v.name})->matchfuzzy("ndl")
results in a list of buffer names fuzzy matching "ndl".
:echo getbufinfo()->matchfuzzy("ndl", {'key' : 'name'})
results in a list of buffer information dicts with buffer
names fuzzy matching "ndl".
:echo getbufinfo()->matchfuzzy("spl",
\ {'text_cb' : {v -> v.name}})
results in a list of buffer information dicts with buffer
names fuzzy matching "spl".
:echo v:oldfiles->matchfuzzy("test")
results in a list of file names fuzzy matching "test".
:let l = readfile("buffer.c")->matchfuzzy("str")
results in a list of lines in "buffer.c" fuzzy matching "str".
:echo ['one two', 'two one']->matchfuzzy('two one')
results in ['two one', 'one two'].
:echo ['one two', 'two one']->matchfuzzy('two one',
\ {'matchseq': 1})
results in ['two one'].
```

Return type: `list<string>` or `list<any>`

`matchfuzzypos({list}, {str} [, {dict}])` `matchfuzzypos()`  
Same as `matchfuzzy()`, but returns the list of matched strings, the list of character positions where characters in `{str}` matches and a list of matching scores. You can use `byteidx()` to convert a character position to a byte position.

If `{str}` matches multiple times in a string, then only the positions for the best match is returned.

If there are no matching strings or there is an error, then a list with three empty list items is returned.

Example:

```

:echo matchfuzzypos(['testing'], 'tsg')
results in [['testing'], [[0, 2, 6]], [99]]
:echo matchfuzzypos(['clay', 'lacy'], 'la')
results in [['lacy', 'clay'], [[0, 1], [1, 2]], [153, 133]]
:echo [{'text': 'hello', 'id' : 10}]->matchfuzzypos('ll', {'key' :
results in [[{'id': 10, 'text': 'hello'}], [[2, 3]], [127]]

```

Return type: list<list<any>>

matchlist({expr}, {pat} [, {start} [, {count}]]]) matchlist()  
 Same as `match()` , but return a `List` . The first item in the list is the matched string, same as what `matchstr()` would return. Following items are submatches, like "\1", "\2", etc. in `:substitute` . When an optional submatch didn't match an empty string is used. Example:

```

:echo matchlist('acd', '\(a\)?\(b\)?\(c\)?\(.*\)')
Results in: ['acd', 'a', '', 'c', 'd', '', '', '', '', '']
When there is no match an empty list is returned.

```

You can pass in a List, but that is not very useful.

Can also be used as a `method` :  
`GetText()->matchlist('word')`

Return type: list<string> or list<any>

matchstrlist()

matchstrlist({list}, {pat} [, {dict}])  
 Returns the `List` of matches in {list} where {pat} matches. {list} is a `List` of strings. {pat} is matched against each string in {list}.

The {dict} argument supports following items:  
 submatches include submatch information ( /\( )

For each match, a `Dict` with the following items is returned:

- byteidx starting byte index of the match.
- idx index in {list} of the match.
- text matched string
- submatches a List of submatches. Present only if "submatches" is set to v:true in {dict}.

See `match-pattern` for information about the effect of some option settings on the pattern.

Example:

```

:echo matchstrlist(['tik tok'], '\<k\+>')
[{'idx': 0, 'byteidx': 0, 'text': 'tik'}, {'idx': 0, 'byteidx': 4, 'text': 'tok'}]
:echo matchstrlist(['a', 'b'], '\<k\+>')
[{'idx': 0, 'byteidx': 0, 'text': 'a'}, {'idx': 1, 'byteidx': 0, 'text': 'b'}]

```

If "submatches" is present and is v:true, then submatches like

"\1", "\2", etc. are also returned. Example:  
:echo matchstrlist(['acd'], '\(a\)?\(b\)?\(c\)?\(.\*\)')  
 \ # {submatches: v:true}  
 [ { 'idx': 0, 'byteidx': 0, 'text': 'acd', 'submatches': ['a', '', 'c',  
The "submatches" List always contains 9 items. If a submatch  
is not found, then an empty string is returned for that  
submatch.

Can also be used as a `method` :  
GetListOfStrings()->matchstrlist('mypat')

Return type: list<dict<any>> or list<any>

matchstr({expr}, {pat} [, {start} [, {count}]]]) `matchstr()`

Same as `match()` , but return the matched string. Example:

:echo matchstr("testing", "ing")  
results in "ing".

When there is no match "" is returned.

The {start}, if given, has the same meaning as for `match()` .

:echo matchstr("testing", "ing", 2)  
results in "ing".

:echo matchstr("testing", "ing", 5)  
result is "".

When {expr} is a `List` then the matching item is returned.  
The type isn't changed, it's not necessarily a String.

Can also be used as a `method` :  
GetText()->matchstr('word')

Return type: `String`

matchstrpos({expr}, {pat} [, {start} [, {count}]]]) `matchstrpos()`

Same as `matchstr()` , but return the matched string, the start  
position and the end position of the match. Example:

:echo matchstrpos("testing", "ing")  
results in ["ing", 4, 7].

When there is no match ["", -1, -1] is returned.

The {start}, if given, has the same meaning as for `match()` .

:echo matchstrpos("testing", "ing", 2)  
results in ["ing", 4, 7].

:echo matchstrpos("testing", "ing", 5)  
result is ["", -1, -1].

When {expr} is a `List` then the matching item, the index  
of first item where {pat} matches, the start position and the  
end position of the match are returned.

:echo matchstrpos([1, '\_\_x'], '\a')  
result is ["x", 1, 2, 3].

The type isn't changed, it's not necessarily a String.

Can also be used as a `method` :  
GetText()->matchstrpos('word')

Return type: list<any>

max({expr})

max()

Return the maximum value of all items in {expr}. Example:  
echo max([apples, pears, oranges])

{expr} can be a List or a Dictionary . For a Dictionary, it returns the maximum of all values in the Dictionary. If {expr} is neither a List nor a Dictionary, or one of the items in {expr} cannot be used as a Number this results in an error. An empty List or Dictionary results in zero.

Can also be used as a method :

mylist->max()

Return type: Number

menu\_info({name} [, {mode}])

menu\_info()

Return information about the specified menu {name} in mode {mode}. The menu name should be specified without the shortcut character ('&'). If {name} is "", then the top-level menu names are returned.

{mode} can be one of these strings:

"n"	Normal
"v"	Visual (including Select)
"o"	Operator-pending
"i"	Insert
"c"	Cmd-line
"s"	Select
"x"	Visual
"t"	Terminal-Job
""	Normal, Visual and Operator-pending
!"	Insert and Cmd-line

When {mode} is omitted, the modes for "" are used.

Returns a Dictionary containing the following items:

accel	menu item accelerator text menu-text
display	display name (name without '&')
enabled	v:true if this menu item is enabled Refer to :menu-enable
icon	name of the icon file (for toolbar) toolbar-icon
iconidx	index of a built-in icon
modes	modes for which the menu is defined. In addition to the modes mentioned above, these characters will be used: " " Normal, Visual and Operator-pending
name	menu item name.
noremenu	v:true if the {rhs} of the menu item is not remappable else v:false.
priority	menu order priority menu-priority

rhs	right-hand-side of the menu item. The returned string has special characters translated like in the output of the ":menu" command listing. When the {rhs} of a menu item is empty, then "<Nop>" is returned.
script	v:true if script-local remapping of {rhs} is allowed else v:false. See :menu-script .
shortcut	shortcut key (character after '&' in the menu name) menu-shortcut
silent	v:true if the menu item is created with <silent> argument :menu-silent
submenus	List containing the names of all the submenus. Present only if the menu item has submenus.

Returns an empty dictionary if the menu item is not found.

Examples:

```

:echo menu_info('Edit.Cut')
:echo menu_info('File.Save', 'n')

" Display the entire menu hierarchy in a buffer
func ShowMenu(name, pfx)
 let m = menu_info(a:name)
 call append(line('$'), a:pfx .. m.display)
 for child in m->get('submenus', [])
 call ShowMenu(a:name .. '.' .. escape(child, '.'),
 \ a:pfx .. ' ')
 endfor
endfunc
new
for topmenu in menu_info('').submenus
 call ShowMenu(topmenu, '')
endfor

```

Can also be used as a method :  
 GetMenuName()->menu\_info('v')

Return type: dict<any>

min({expr})

min()

Return the minimum value of all items in {expr}. Example:  
 echo min([apples, pears, oranges])

{expr} can be a List or a Dictionary . For a Dictionary, it returns the minimum of all values in the Dictionary. If {expr} is neither a List nor a Dictionary, or one of the items in {expr} cannot be used as a Number this results in an error. An empty List or Dictionary results in zero.

Can also be used as a method :  
 mylist->min()

Return type: Number

`mkdir({name} [, {flags} [, {prot}]])` `mkdir()` E739  
Create directory `{name}`.

When `{flags}` is present it must be a string. An empty string has no effect.

`{flags}` can contain these character flags:  
"p" intermediate directories will be created as necessary  
"D" `{name}` will be deleted at the end of the current function, but not recursively `:defer`  
"R" `{name}` will be deleted recursively at the end of the current function `:defer`

**Note** that when `{name}` has more than one part and "p" is used some directories may already exist. Only the first one that is created and what it contains is scheduled to be deleted. E.g. when using:

```
call mkdir('subdir/tmp/autoload', 'pR')
and "subdir" already exists then "subdir/tmp" will be
scheduled for deletion, like with:
defer delete('subdir/tmp', 'rf')
```

**Note** that if scheduling the `defer` fails the directory is not deleted. This should only happen when out of memory.

If `{prot}` is given it is used to set the protection bits of the new directory. The default is `0o755` (`rw-r-xr-x`: r/w for the user, readable for others). Use `0o700` to make it unreadable for others. This is used for the newly created directories. **Note:** `umask` is applied to `{prot}` (on Unix).  
Example:

```
:call mkdir($HOME .. "/tmp/foo/bar", "p", 0o700)
```

This function is not available in the `sandbox`.

There is no error if the directory already exists and the "p" flag is passed (since patch 8.0.1708). However, without the "p" option the call will fail.

The function result is a `Number`, which is `TRUE` if the call was successful or `FALSE` if the directory creation failed or partly failed.

Not available on all systems. To check use:  
`:if exists("*mkdir")`

Can also be used as a `method` :  
`GetName()->mkdir()`

Return type: `Number`

`mode([{{expr}}])` `mode()`

Return a string that indicates the current mode.  
 If {expr} is supplied and it evaluates to a non-zero Number or a non-empty String ( non-zero-arg ), then the full mode is returned, otherwise only the first letter is returned.  
 Also see state() .

```

n Normal
no Operator-pending
nov Operator-pending (forced characterwise o_v)
noV Operator-pending (forced linewise o_V)
noCTRL-V Operator-pending (forced blockwise o_CTRL-V);
 CTRL-V is one character

ce Normal Ex mode Q
r Hit-enter prompt
rm The -- more -- prompt
r? A :confirm query of some sort
! Shell or external command is executing
t Terminal-Job mode: keys go to the job

```

This is useful in the 'statusline' option or when used with remote\_expr() In most other places it always returns "c" or "n".

**Note** that in the future more modes and more specific modes may be added. It's better not to compare the whole string but only the leading character(s).

Also see visualmode() .

Can also be used as a `method` :  
`DoFull()->mode()`

Return type: `String`

`mzeval({expr})`

`mzeval()`

Evaluate MzScheme expression `{expr}` and return its result converted to Vim data structures. Numbers and strings are returned as they are. Pairs (including lists and improper lists) and vectors are returned as Vim `Lists` . Hash tables are represented as Vim `Dictionary` type with keys converted to strings. All other types are converted to string with display function. Examples:

```
:mz (define l (list 1 2 3))
:mz (define h (make-hash)) (hash-set! h "list" l)
:echo mzeval("l")
:echo mzeval("h")
```

**Note** that in a `:def` function local variables are not visible to `{expr}`.

Can also be used as a `method` :  
`GetExpr()->mzeval()`

Return type: any, depending on `{expr}`

`{only available when compiled with the |+mzscheme| feature}`

`nextnonblank({lnum})`

`nextnonblank()`

Return the line number of the first line at or below `{lnum}` that is not blank. Example:

```
if getline(nextnonblank(1)) =~ "Java"
```

When `{lnum}` is invalid or there is no non-blank line at or below it, zero is returned.

`{lnum}` is used like with `getline()` .

See also `prevnonblank()` .

Can also be used as a `method` :  
`GetLnum()->nextnonblank()`

Return type: `Number`

`ngettext({single}, {plural}, {number}[, {domain}])`

`ngettext()`

Return a string that contains the correct value for a message based on the rules for plural form(s) in a language. Examples:

```
ngettext("File", "Files", 2) # returns "Files"
```

Can be used as a `method` :

```
1->gettext("File", "Files") # returns "File"
```

See `gettext()` for information on the domain parameter.

Return type: `String`

```
nr2char({expr} [, {utf8}]) nr2char()
```

Return a string with a single character, which has the number value `{expr}`. Examples:

```
nr2char(64) returns "@"
nr2char(32) returns " "
```

When `{utf8}` is omitted or zero, the current `'encoding'` is used.

Example for "utf-8":

```
nr2char(300) returns I with bow character
```

When `{utf8}` is TRUE, always return UTF-8 characters.

**Note** that a NUL character in the file is specified with `nr2char(10)`, because NULs are represented with newline characters. `nr2char(0)` is a real NUL and terminates the string, thus results in an empty string.

To turn a list of character numbers into a string:

```
let list = [65, 66, 67]
let str = join(map(list, {_, val -> nr2char(val)}), '')
```

Result: "ABC"

Can also be used as a `method` :

```
GetNumber()->nr2char()
```

Return type: `String`

```
or({expr}, {expr}) or()
```

Bitwise OR on the two arguments. The arguments are converted to a number. A List, Dict or Float argument causes an error. Also see `'and()'` and `'xor()'`.

Example:

```
:let bits = or(bits, 0x80)
```

Can also be used as a `method` :

```
:let bits = bits->or(0x80)
```

**Rationale:** The reason this is a function and not using the `"|"` character like many languages, is that Vi has always used `"|"` to separate commands. In many places it would not be clear if `"|"` is an operator or a command separator.

Return type: `Number`

```
pathshorten({path} [, {len}]) pathshorten()
```

Shorten directory names in the path `{path}` and return the result. The tail, the file name, is kept as-is. The other components in the path are reduced to `{len}` letters in length. If `{len}` is omitted or smaller than 1 then 1 is used (single letters). Leading `'~'` and `'.'` characters are kept. Examples:

```
:echo pathshorten('~/.vim/autoload/myfile.vim')
~/.v/a/myfile.vim

:echo pathshorten('~/.vim/autoload/myfile.vim', 2)
~/.vi/au/myfile.vim
```

It doesn't matter if the path exists or not.  
Returns an empty string on error.

Can also be used as a [method](#) :  
`GetDirectories()->pathshorten()`

Return type: [String](#)

`perlevel({expr})`

[perlevel\(\)](#)

Evaluate Perl expression `{expr}` in scalar context and return its result converted to Vim data structures. If value can't be converted, it is returned as a string Perl representation.

**Note:** If you want an array or hash, `{expr}` must return a reference to it.

Example:

```
:echo perlevel('[1 .. 4]')
[1, 2, 3, 4]
```

**Note** that in a `:def` function local variables are not visible to `{expr}`.

Can also be used as a [method](#) :  
`GetExpr()->perlevel()`

Return type: any, depending on `{expr}`

[{only available when compiled with the |+perl| feature}](#)

`popup_` functions are documented here: [popup-functions](#)

`pow({x}, {y})`

[pow\(\)](#)

Return the power of `{x}` to the exponent `{y}` as a [Float](#) .  
`{x}` and `{y}` must evaluate to a [Float](#) or a [Number](#) .

Returns 0.0 if `{x}` or `{y}` is not a [Float](#) or a [Number](#) .

Examples:

```
:echo pow(3, 3)
27.0
:echo pow(2, 16)
65536.0
:echo pow(32, 0.20)
2.0
```

Can also be used as a [method](#) :  
`Compute()->pow(3)`

Return type: [Number](#)

prevnonblank({lnum}) prevnonblank()  
 Return the line number of the first line at or above {lnum} that is not blank. Example:  
`let ind = indent(prevnonblank(v:lnum - 1))`  
 When {lnum} is invalid or there is no non-blank line at or above it, zero is returned.  
 {lnum} is used like with `getline()` .  
 Also see `nextnonblank()` .

Can also be used as a `method` :  
`GetLnum()->prevnonblank()`

Return type: `Number`

printf({fmt}, {expr1} ...) printf()  
 Return a String with {fmt}, where "%" items are replaced by the formatted form of their respective arguments. Example:  
`printf("%4d: E%d %.30s", lnum, errno, msg)`  
 May result in:  
`" 99: E42 asdfasdfasdfasdfasdfasdfas"`

When used as a `method` the base is passed as the second argument:  
`Compute()->printf("result: %d")`

You can use ``call()`` to pass the items as a list.

Often used items are:

%s	string
%6S	string right-aligned in 6 display cells
%6s	string right-aligned in 6 bytes
%.9s	string truncated to 9 bytes
%c	single byte
%d	decimal number
%5d	decimal number padded with spaces to 5 characters
%x	hex number
%04x	hex number padded with zeros to at least 4 characters
%X	hex number using upper case letters
%o	octal number
%08b	binary number padded with zeros to at least 8 chars
%f	floating point number as 12.23, inf, -inf or nan
%F	floating point number as 12.23, INF, -INF or NAN
%e	floating point number as 1.23e3, inf, -inf or nan
%E	floating point number as 1.23E3, INF, -INF or NAN
%g	floating point number, as %f or %e depending on value
%G	floating point number, as %F or %E depending on value
%%	the % character itself

Conversion specifications start with '%' and end with the conversion type. All other characters are copied unchanged to the result.

The "%" starts a conversion specification. The following arguments appear in sequence:

% [pos-argument] [flags] [field-width] [.precision] type

#### pos-argument

At most one positional argument specifier. These take the form {n\$}, where n is >= 1.

#### flags

Zero or more of the following flags:

- # The value should be converted to an "alternate form". For c, d, and s conversions, this option has no effect. For o conversions, the precision of the number is increased to force the first character of the output string to a zero (except if a zero value is printed with an explicit precision of zero).  
For b and B conversions, a non-zero result has the string "0b" (or "0B" for B conversions) prepended to it.  
For x and X conversions, a non-zero result has the string "0x" (or "0X" for X conversions) prepended to it.
- 0 (zero) Zero padding. For all conversions the converted value is padded on the left with zeros rather than blanks. If a precision is given with a numeric conversion (d, b, B, o, x, and X), the 0 flag is ignored.
- A negative field width flag; the converted value is to be left adjusted on the field boundary. The converted value is padded on the right with blanks, rather than on the left with blanks or zeros. A - overrides a 0 if both are given.
- ' ' (space) A blank should be left before a positive number produced by a signed conversion (d).
- + A sign must always be placed before a number produced by a signed conversion. A + overrides a space if both are used.

#### field-width

An optional decimal digit string specifying a minimum field width. If the converted value has fewer bytes than the field width, it will be padded with spaces on the left (or right, if the left-adjustment flag has been given) to fill out the field width. For the S conversion the count is in cells.

### .precision

An optional precision, in the form of a period '.' followed by an optional digit string. If the digit string is omitted, the precision is taken as zero. This gives the minimum number of digits to appear for d, o, x, and X conversions, the maximum number of bytes to be printed from a string for s conversions, or the maximum number of cells to be printed from a string for S conversions. For floating point it is the number of digits after the decimal point.

### type

A character that specifies the type of conversion to be applied, see below.

A field width or precision, or both, may be indicated by an asterisk '\*' instead of a digit string. In this case, a Number argument supplies the field width or precision. A negative field width is treated as a left adjustment flag followed by a positive field width; a negative precision is treated as though it were missing. Example:

```
:echo printf("%d: %.*s", nr, width, line)
```

This limits the length of the text used from "line" to "width" bytes.

If the argument to be formatted is specified using a positional argument specifier, and a '\*' is used to indicate that a number argument is to be used to specify the width or precision, the argument(s) to be used must also be specified using a {n\$} positional argument specifier. See [printf-\\$](#).

The conversion specifiers and their meanings are:

```
printf-d printf-b printf-B printf-o
printf-x printf-X
```

dbBoxX The Number argument is converted to signed decimal (d), unsigned binary (b and B), unsigned octal (o), or unsigned hexadecimal (x and X) notation. The letters "abcdef" are used for x conversions; the letters "ABCDEF" are used for X conversions.

The precision, if any, gives the minimum number of digits that must appear; if the converted value requires fewer digits, it is padded on the left with zeros.

In no case does a non-existent or small field width cause truncation of a numeric field; if the result of a conversion is wider than the field width, the field is expanded to contain the conversion result.

The 'h' modifier indicates the argument is 16 bits.

The 'l' modifier indicates the argument is a long integer. The size will be 32 bits or 64 bits depending on your platform.

The "ll" modifier indicates the argument is 64 bits.

The b and B conversion specifiers never take a width modifier and always assume their argument is a 64 bit integer.

Generally, these modifiers are not useful. They are ignored when type is known from the argument.

i alias for d  
D alias for ld  
U alias for lu  
O alias for lo

#### printf-c

c The Number argument is converted to a byte, and the resulting character is written.

#### printf-s

s The text of the String argument is used. If a precision is specified, no more bytes than the number specified are used.

If the argument is not a String type, it is automatically converted to text with the same format as "echo".

#### printf-S

S The text of the String argument is used. If a precision is specified, no more display cells than the number specified are used.

#### printf-f E807

f F The Float argument is converted into a string of the form 123.456. The precision specifies the number of digits after the decimal point. When the precision is zero the decimal point is omitted. When the precision is not specified 6 is used. A really big number (out of range or dividing by zero) results in "inf" or "-inf" with %f (INF or -INF with %F). "0.0 / 0.0" results in "nan" with %f (NAN with %F).  
Example:

```
echo printf("%.2f", 12.115)
```

```
12.12
```

Note that roundoff depends on the system libraries. Use `round()` when in doubt.

#### printf-e printf-E

e E The Float argument is converted into a string of the form 1.234e+03 or 1.234E+03 when using 'E'. The precision specifies the number of digits after the decimal point, like with 'f'.

#### printf-g printf-G

g G The Float argument is converted like with 'f' if the value is between 0.001 (inclusive) and 10000000.0 (exclusive). Otherwise 'e' is used for 'g' and 'E' for 'G'. When no precision is specified superfluous zeroes and '+' signs are removed, except for the zero

immediately after the decimal point. Thus 10000000.0 results in 1.0e7.

#### printf-%

% A '%' is written. No argument is converted. The complete conversion specification is "%%".

When a Number argument is expected a String argument is also accepted and automatically converted.  
When a Float or String argument is expected a Number argument is also accepted and automatically converted.  
Any other argument type results in an error message.

#### E766 E767

The number of {exprN} arguments must exactly match the number of "%" items. If there are not sufficient or too many arguments an error is given. Up to 18 arguments can be used.

#### printf-\$

In certain languages, error and informative messages are more readable when the order of words is different from the corresponding message in English. To accommodate translations having a different word order, positional arguments may be used to indicate this. For instance:

```
#, c-format
msgid "%s returning %s"
msgstr "waarde %2$s komt terug van %1$s"
```

In this example, the sentence has its 2 string arguments reversed in the output.

```
echo printf(
 "In The Netherlands, vim's creator's name is: %1$s %2$s",
 "Bram", "Moolenaar")
```

In The Netherlands, vim's creator's name is: Bram Moolenaar

```
echo printf(
 "In Belgium, vim's creator's name is: %2$s %1$s",
 "Bram", "Moolenaar")
```

In Belgium, vim's creator's name is: Moolenaar Bram

Width (and precision) can be specified using the '\*' specifier. In this case, you must specify the field width position in the argument list.

```
echo printf("%1$*2$.*3$d", 1, 2, 3)
001
echo printf("%2$*3$.*1$d", 1, 2, 3)
2
echo printf("%3$*1$.*2$d", 1, 2, 3)
03
echo printf("%1$*2$.*3$g", 1.4142, 2, 3)
1.414
```

You can mix specifying the width and/or precision directly and via positional arguments:

```
echo printf("%1$4.*2$f", 1.4142135, 6)
1.414214
echo printf("%1$*2$.4f", 1.4142135, 6)
1.4142
echo printf("%1$*2$.*3$f", 1.4142135, 6, 2)
1.41
```

You will get an overflow error `E1510`, when the field-width or precision will result in a string longer than 6400 chars.

`E1500`

You cannot mix positional and non-positional arguments:

```
echo printf("%s%1$s", "One", "Two")
E1500: Cannot mix positional and non-positional arguments:
%s%1$s
```

`E1501`

You cannot skip a positional argument in a format string:

```
echo printf("%3$s%1$s", "One", "Two", "Three")
E1501: format argument 2 unused in $-style format:
%3$s%1$s
```

`E1502`

You can re-use a `[field-width]` (or `[precision]`) argument:

```
echo printf("%1$d at width %2$d is: %01$*2$d", 1, 2)
1 at width 2 is: 01
```

However, you can't use it as a different type:

```
echo printf("%1$d at width %2$ld is: %01$*2$d", 1, 2)
E1502: Positional argument 2 used as field width reused as
different type: long int/int
```

`E1503`

When a positional argument is used, but not the correct number or arguments is given, an error is raised:

```
echo printf("%1$d at width %2$d is: %01$*2$.*3$d", 1, 2)
E1503: Positional argument 3 out of bounds: %1$d at width
%2$d is: %01$*2$.*3$d
```

Only the first error is reported:

```
echo printf("%01$*2$.*3$d %4$d", 1, 2)
E1503: Positional argument 3 out of bounds: %01$*2$.*3$d
%4$d
```

`E1504`

A positional argument can be used more than once:

```
echo printf("%1$s %2$s %1$s", "One", "Two")
One Two One
```

However, you can't use a different type the second time:

```
echo printf("%1$s %2$s %1$d", "One", "Two")
E1504: Positional argument 1 type used inconsistently:
int/string
```

E1505

Various other errors that lead to a format string being wrongly formatted lead to:

```
echo printf("%1$d at width %2$d is: %01$*2$.3$d", 1, 2)
E1505: Invalid format specifier: %1$d at width %2$d is:
%01$*2$.3$d
```

E1507

This internal error indicates that the logic to parse a positional format argument ran into a problem that couldn't be otherwise reported. Please file a bug against Vim if you run into this, copying the exact format string and parameters that were used.

Return type: [String](#)

`prompt_getprompt({buf})` [prompt\\_getprompt\(\)](#)  
Returns the effective prompt text for buffer `{buf}`. `{buf}` can be a buffer name or number. See [prompt-buffer](#).

If the buffer doesn't exist or isn't a prompt buffer, an empty string is returned.

Can also be used as a [method](#) :  
`GetBuffer()->prompt_getprompt()`

Return type: [String](#)

[{only available when compiled with the |+channel| feature}](#)

`prompt_setcallback({buf}, {expr})` [prompt\\_setcallback\(\)](#)  
Set prompt callback for buffer `{buf}` to `{expr}`. When `{expr}` is an empty string the callback is removed. This has only effect if `{buf}` has `'buftype'` set to "prompt".

The callback is invoked when pressing Enter. The current buffer will always be the prompt buffer. A new line for a prompt is added before invoking the callback, thus the prompt for which the callback was invoked will be in the last but one line.

If the callback wants to add text to the buffer, it must insert it above the last line, since that is where the current prompt is. This can also be done asynchronously.

The callback is invoked with one argument, which is the text that was entered at the prompt. This can be an empty string if the user only typed Enter.

Example:

```
func s:TextEntered(text)
```

```

if a:text == 'exit' || a:text == 'quit'
 stopinsert
 " Reset 'modified' to allow the buffer to be closed.
 " We assume there is nothing useful to be saved.
 set nomodified
 close
else
 " Do something useful with "a:text". In this example
 " we just repeat it.
 call append(line('$') - 1, 'Entered: "' .. a:text .. "')
endif
endfunc
call prompt_setcallback(bufnr(), function('s:TextEntered'))

```

Can also be used as a [method](#) :

```
GetBuffer()->prompt_setcallback(callback)
```

{only available when compiled with the |+channel| feature}

```
prompt_setinterrupt({buf}, {expr}) prompt_setinterrupt\(\)
Set a callback for buffer {buf} to {expr}. When {expr} is an
empty string the callback is removed. This has only effect if
{buf} has 'buftype' set to "prompt".
```

This callback will be invoked when pressing **CTRL-C** in Insert mode. Without setting a callback Vim will exit Insert mode, as in any buffer.

Can also be used as a [method](#) :

```
GetBuffer()->prompt_setinterrupt(callback)
```

Return type: [Number](#)

{only available when compiled with the |+channel| feature}

```
prompt_setprompt({buf}, {text}) prompt_setprompt\(\)
Set prompt for buffer {buf} to {text}. You most likely want
{text} to end in a space.
The result is only visible if {buf} has 'buftype' set to
"prompt". Example:
```

```
call prompt_setprompt(bufnr(), 'command: ')

```

Can also be used as a [method](#) :

```
GetBuffer()->prompt_setprompt('command: ')

```

Return type: [Number](#)

{only available when compiled with the |+channel| feature}

prop\_ functions are documented here: [text-prop-functions](#)

```
pum_getpos() pum_getpos\(\)
```

If the popup menu (see [ins-completion-menu](#) ) is not visible, returns an empty [Dictionary](#) , otherwise, returns a

**Dictionary** with the following keys:

height	nr of items visible
width	screen cells
row	top screen row (0 first row)
col	leftmost screen column (0 first col)
size	total nr of items
scrollbar	<b>TRUE</b> if scrollbar is visible

The values are the same as in `v:event` during `CompleteChanged` .

Return type: dict<any>

`pumvisible()` `pumvisible()`

Returns non-zero when the popup menu is visible, zero otherwise. See `ins-completion-menu` . This can be used to avoid some things that would remove the popup menu.

Return type: `Number`

`py3eval({expr} [, {locals}])` `py3eval()`

Evaluate Python expression `{expr}` and return its result converted to Vim data structures. If a `{locals}` `Dictionary` is given, it defines set of local variables available in the expression. The keys are variable names and the values are the variable values. `Dictionary` and `List` values are referenced, and may be updated by the expression (as if `python-bindeval` was used). Numbers and strings are returned as they are (strings are copied though, Unicode strings are additionally converted to `'encoding'`). Lists are represented as Vim `List` type. Dictionaries are represented as Vim `Dictionary` type with keys converted to strings. **Note** that in a `:def` function local variables are not visible to {expr}.`

Can also be used as a `method` :

```
GetExpr()->py3eval()
'b",".join(l)'->py3eval({'l': ['a', 'b', 'c']})
```

Return type: any, depending on `{expr}`

`{only available when compiled with the |+python3| feature}`

`pyeval({expr} [, {locals}])` `E858 E859`  
`pyeval()`

Evaluate Python expression `{expr}` and return its result converted to Vim data structures. For `{locals}` see `py3eval()` . Numbers and strings are returned as they are (strings are

copied though).

Lists are represented as Vim `List` type.

Dictionaries are represented as Vim `Dictionary` type, non-string keys result in error.

**Note** that in a `:def` function local variables are not visible to `{expr}`.

Can also be used as a `method` :

```
GetExpr()->pyeval()
```

Return type: any, depending on `{expr}`

{only available when compiled with the `|+python|` feature}

`pyxeval({expr} [, {locals}])` `pyxeval()`

Evaluate Python expression `{expr}` and return its result converted to Vim data structures.

For `{locals}` see `py3eval()` .

Uses Python 2 or 3, see `python_x` and `'pyxversion'`.

See also: `pyeval()` , `py3eval()`

Can also be used as a `method` :

```
GetExpr()->pyxeval()
```

Return type: any, depending on `{expr}`

{only available when compiled with the `+python` or the `+python3` feature}

`rand([ {expr} ])` `rand()` `random`

Return a pseudo-random Number generated with an xoshiro128\*\* algorithm using seed `{expr}`. The returned number is 32 bits, also on 64 bits systems, for consistency.

`{expr}` can be initialized by `srand()` and will be updated by `rand()`. If `{expr}` is omitted, an internal seed value is used and updated.

Returns -1 if `{expr}` is invalid.

Examples:

```
:echo rand()
:let seed = srand()
:echo rand(seed)
:echo rand(seed) % 16 " random number 0 - 15
```

Return type: `Number`

`range({expr} [, {max} [, {stride}]])` `E726` `E727`  
`range()`

Returns a `List` with Numbers:

- If only `{expr}` is specified: `[0, 1, ..., {expr} - 1]`
- If `{max}` is specified: `[{expr}, {expr} + 1, ..., {max}]`
- If `{stride}` is specified: `[{expr}, {expr} + {stride}, ..., {max}]` (increasing `{expr}` with `{stride}` each time, not producing a value past `{max}`).

When the maximum is one before the start the result is an empty list. When the maximum is more than one before the start this is an error.

Examples:

```
range(4) " [0, 1, 2, 3]
range(2, 4) " [2, 3, 4]
range(2, 9, 3) " [2, 5, 8]
range(2, -2, -1) " [2, 1, 0, -1, -2]
range(0) " []
range(2, 0) " error!
```

Can also be used as a `method` :

```
GetExpr()->range()
```

Return type: `list<number>`

```
readblob({fname} [, {offset} [, {size}]]]) readblob()
```

Read file `{fname}` in binary mode and return a `Blob` .

If `{offset}` is specified, read the file from the specified offset. If it is a negative value, it is used as an offset from the end of the file. E.g., to read the last 12 bytes:

```
readblob('file.bin', -12)
```

If `{size}` is specified, only the specified size will be read.

E.g. to read the first 100 bytes of a file:

```
readblob('file.bin', 0, 100)
```

If `{size}` is -1 or omitted, the whole data starting from `{offset}` will be read.

This can be also used to read the data from a character device on Unix when `{size}` is explicitly set. Only if the device supports seeking `{offset}` can be used. Otherwise it should be zero. E.g. to read 10 bytes from a serial console:

```
readblob('/dev/ttyS0', 0, 10)
```

When the file can't be opened an error message is given and the result is an empty `Blob` .

When the offset is beyond the end of the file the result is an empty blob.

When trying to read more bytes than are available the result is truncated.

Also see `readfile()` and `writefile()` .

Return type: `Blob`

```
readdir({directory} [, {expr} [, {dict}]]]) readdir()
```

Return a list with file and directory names in `{directory}`.

You can also use `glob()` if you don't need to do complicated things, such as limiting the number of matches.

The list will be sorted (case sensitive), see the `{dict}` argument below for changing the sort order.

When `{expr}` is omitted all entries are included.

When `{expr}` is given, it is evaluated to check what to do:

If `{expr}` results in -1 then no further entries will

be handled.

If `{expr}` results in 0 then this entry will not be added to the list.

If `{expr}` results in 1 then this entry will be added to the list.

The entries "." and ".." are always excluded.

Each time `{expr}` is evaluated `v:val` is set to the entry name.

When `{expr}` is a function the name is passed as the argument.

For example, to get a list of files ending in ".txt":

```
readdir(dirname, {n -> n =~ '.txt$'})
```

To skip hidden and backup files:

```
readdir(dirname, {n -> n !~ '^\.|\~$'})
```

E857

The optional `{dict}` argument allows for further custom values. Currently this is used to specify if and how sorting should be performed. The dict can have the following members:

sort	How to sort the result returned from the system. Valid values are:
"none"	do not sort (fastest method)
"case"	sort case sensitive (byte value of each character, technically, using <code>strcmp()</code> ) (default)
"icase"	sort case insensitive (technically using <code>strcasecmp()</code> )
"collate"	sort using the collation order of the "POSIX" or "C" <code>locale</code> (technically using <code>strcoll()</code> )

Other values are silently ignored.

For example, to get a list of all files in the current directory without sorting the individual entries:

```
readdir('.', '1', #{sort: 'none'})
```

If you want to get a directory tree:

```
function! s:tree(dir)
 return {a:dir : map(readdir(a:dir),
 \ {_, x -> isdirectory(x) ?
 \ {x : s:tree(a:dir .. '/' .. x)} : x)}}
endfunction
echo s:tree(".")
```

Returns an empty List on error.

Can also be used as a `method` :

```
GetDirName()->readdir()
```

Return type: `list<string>` or `list<any>`

`readdir({directory} [, {expr} [, {dict}]])` readdir()

Extended version of `readdir()` .

Return a list of Dictionaries with file and directory information in `{directory}`.

This is useful if you want to get the attributes of file and

directory at the same time as getting a list of a directory. This is much faster than calling `readdir()` then calling `getfperm()`, `getfsize()`, `getftime()` and `getftype()` for each file and directory especially on MS-Windows. The list will by default be sorted by name (case sensitive), the sorting can be changed by using the optional `{dict}` argument, see `readdir()`.

The Dictionary for file and directory information has the following items:

<code>group</code>	Group name of the entry. (Only on Unix)
<code>name</code>	Name of the entry.
<code>perm</code>	Permissions of the entry. See <code>getfperm()</code> .
<code>size</code>	Size of the entry. See <code>getfsize()</code> .
<code>time</code>	Timestamp of the entry. See <code>getftime()</code> .
<code>type</code>	Type of the entry. On Unix, almost same as <code>getftype()</code> except: Symlink to a dir     "linkd" Other symlink       "link" On MS-Windows: Normal file         "file" Directory          "dir" Junction           "junction" Symlink to a dir    "linkd" Other symlink       "link" Other reparse point "reparse"
<code>user</code>	User name of the entry's owner. (Only on Unix)

On Unix, if the entry is a symlink, the Dictionary includes the information of the target (except the "type" item).

On MS-Windows, it includes the information of the symlink itself because of performance reasons.

When `{expr}` is omitted all entries are included.

When `{expr}` is given, it is evaluated to check what to do:

If `{expr}` results in -1 then no further entries will be handled.

If `{expr}` results in 0 then this entry will not be added to the list.

If `{expr}` results in 1 then this entry will be added to the list.

The entries "." and ".." are always excluded.

Each time `{expr}` is evaluated `v:val` is set to a Dictionary of the entry.

When `{expr}` is a function the entry is passed as the argument.

For example, to get a list of files ending in ".txt":

```
readdirrex(dirname, {e -> e.name =~ '.txt$'})
```

For example, to get a list of all files in the current directory without sorting the individual entries:

```
readdirrex(dirname, '1', #{sort: 'none'})
```

Can also be used as a `method` :

```
GetDirName()->readdirrex()
```

Return type: list<dict<any>> or list<any>

### readfile()

readfile({fname} [, {type} [, {max}]])

Read file {fname} and return a List , each line of the file as an item. Lines are broken at NL characters. Macintosh files separated with CR will result in a single long line (unless a NL appears somewhere).

All NUL characters are replaced with a NL character.

When {type} contains "b" binary mode is used:

- When the last line ends in a NL an extra empty list item is added.

- No CR characters are removed.

Otherwise:

- CR characters that appear before a NL are removed.

- Whether the last line ends in a NL or not does not matter.

- When 'encoding' is Unicode any UTF-8 byte order mark is removed from the text.

When {max} is given this specifies the maximum number of lines to be read. Useful if you only want to check the first ten lines of a file:

```
:for line in readfile(fname, '', 10)
: if line =~ 'Date' | echo line | endif
:endfor
```

When {max} is negative -{max} lines from the end of the file are returned, or as many as there are.

When {max} is zero the result is an empty list.

Note that without {max} the whole file is read into memory. Also note that there is no recognition of encoding. Read a file into a buffer if you need to.

Deprecated (use readblob() instead): When {type} contains "B" a Blob is returned with the binary data of the file unmodified.

When the file can't be opened an error message is given and the result is an empty list.

Also see writefile() .

Can also be used as a method :

```
GetFileName()->readfile()
```

Return type: list<string> or list<any>

reduce({object}, {func} [, {initial}]) reduce() E998

{func} is called for every item in {object}, which can be a String , List or a Blob . {func} is called with two arguments: the result so far and current item. After processing all items the result is returned. E1132

{initial} is the initial result. When omitted, the first item in {object} is used and {func} is first called for the second item. If {initial} is not given and {object} is empty no result can be computed, an E998 error is given.

Examples:

```
echo reduce([1, 3, 5], { acc, val -> acc + val })
echo reduce(['x', 'y'], { acc, val -> acc .. val }, 'a')
echo reduce(0z1122, { acc, val -> 2 * acc + val })
echo reduce('xyz', { acc, val -> acc .. ',' .. val })
```

Can also be used as a `method` :

```
echo mylist->reduce({ acc, val -> acc + val }, 0)
```

Return type: `String` , `Blob` , `list<{type}>` or `dict<{type}>`  
depending on `{object}` and `{func}`

`reg_executing()`

`reg_executing()`

Returns the single letter name of the register being executed.  
Returns an empty string when no register is being executed.  
See [@](#) .

Return type: `String`

`reg_recording()`

`reg_recording()`

Returns the single letter name of the register being recorded.  
Returns an empty string when not recording. See [q](#) .

Return type: `String`

`reltime()`

`reltime()`

`reltime({start})`

`reltime({start}, {end})`

Return an item that represents a time value. The item is a list with items that depend on the system. In Vim 9 script the type `list<any>` can be used.

The item can be passed to `reltimestr()` to convert it to a string or `reltimefloat()` to convert to a Float. For example, to see the time spent in function `Work()`:

```
var startTime = reltime()
Work()
echo startTime->reltime()->reltimestr()
```

Without an argument `reltime()` returns the current time (the representation is system-dependent, it cannot be used as the wall-clock time, see `localtime()` for that).

With one argument it returns the time passed since the time specified in the argument.

With two arguments it returns the time passed between `{start}` and `{end}`.

The `{start}` and `{end}` arguments must be values returned by `reltime()`. If there is an error an empty List is returned in legacy script, in Vim9 script an error is given.

Can also be used as a `method` :

`GetStart()->reltime()`

Return type: `list<number>`

{only available when compiled with the `|+reltime|` feature}

`reltimefloat({time})`

`reltimefloat()`

Return a Float that represents the time value of `{time}`.

Example:

```
let start = reltime()
call MyFunction()
let seconds = reltimefloat(reltime(start))
```

See the [note](#) of `reltimestr()` about overhead.

Also see [profiling](#) .

If there is an error 0.0 is returned in legacy script, in Vim9 script an error is given.

Can also be used as a [method](#) :

```
reltime(start)->reltimefloat()
```

Return type: `Float`

{only available when compiled with the `|+reltime|` feature}

`reltimestr({time})`

`reltimestr()`

Return a String that represents the time value of `{time}`.

This is the number of seconds, a dot and the number of microseconds. Example:

```
let start = reltime()
call MyFunction()
echo reltimestr(reltime(start))
```

**Note** that overhead for the commands will be added to the time.

The accuracy depends on the system. Use `reltimefloat()` for the greatest accuracy which is nanoseconds on some systems.

Leading spaces are used to make the string align nicely. You can use `split()` to remove it.

```
echo split(reltimestr(reltime(start)))[0]
```

Also see [profiling](#) .

If there is an error an empty string is returned in legacy script, in Vim9 script an error is given.

Can also be used as a [method](#) :

```
reltime(start)->reltimestr()
```

Return type: `String`

{only available when compiled with the `|+reltime|` feature}

`remote_expr({server}, {string} [, {idvar} [, {timeout}]])`

`remote_expr()` E449

Send the `{string}` to `{server}`. The `{server}` argument is a string, also see [{server}](#) .

The string is sent as an expression and the result is returned after evaluation. The result must be a `String` or a `List` other types will be converted to `String`. A `List` is turned into a `String` by joining the items with a line break in between (not at the end), like with `join(expr, "\n")`.

If `{idvar}` is present and not empty, it is taken as the name of a variable and a `{serverid}` for later use with `remote_read()` is stored there.

If `{timeout}` is given the read times out after this many seconds. Otherwise a timeout of 600 seconds is used.

See also `clientserver RemoteReply` .

This function is not available in the `sandbox` .

`{only available when compiled with the |+clientserver| feature}`

**Note:** Any errors will cause a local error message to be issued and the result will be the empty string.

Variables will be evaluated in the global namespace, independent of a function currently being active. Except when in debug mode, then local function variables and arguments can be evaluated.

Examples:

```
:echo remote_expr("gvim", "2+2")
:echo remote_expr("gvim1", "b:current_syntax")
```

Can also be used as a `method` :

```
ServerName()->remote_expr(expr)
```

Return type: `String` or `list<{type}>`

`remote_foreground({server})` `remote_foreground()`

Move the Vim server with the name `{server}` to the foreground.

The `{server}` argument is a string, also see `{server}` .

This works like:

```
remote_expr({server}, "foreground()")
```

Except that on Win32 systems the client does the work, to work around the problem that the OS doesn't always allow the server to bring itself to the foreground.

**Note:** This does not restore the window if it was minimized, like `foreground()` does.

This function is not available in the `sandbox` .

Can also be used as a `method` :

```
ServerName()->remote_foreground()
```

Return type: `Number`

`{only in the Win32, Motif and GTK GUI versions and the Win32 console version}`

`remote_peek({serverid} [, {retvar}])` `remote_peek()`

Returns a positive number if there are available strings from `{serverid}`. Copies any reply string into the variable `{retvar}` if specified. `{retvar}` must be a string with the name of a variable.

Returns zero if none are available.

Returns -1 if something is wrong.

See also `clientserver` .

This function is not available in the `sandbox` .  
 {only available when compiled with the |+clientserver| feature}

Examples:

```
:let repl = ""
:echo "PEEK: " .. remote_peek(id, "repl") .. ": " .. repl
```

Can also be used as a `method` :

```
ServerId()->remote_peek()
```

Return type: `Number`

`remote_read({serverid}, [{timeout}])` `remote_read()`

Return the oldest available reply from `{serverid}` and consume it. Unless a `{timeout}` in seconds is given, it blocks until a reply is available. Returns an empty string, if a reply is not available or on error.

See also `clientserver` .

This function is not available in the `sandbox` .  
 {only available when compiled with the |+clientserver| feature}

Example:

```
:echo remote_read(id)
```

Can also be used as a `method` :

```
ServerId()->remote_read()
```

Return type: `String`

`remote_send({server}, {string} [, {idvar}])` `remote_send()` E241

Send the `{string}` to `{server}`. The `{server}` argument is a string, also see `{server}` .

The string is sent as input keys and the function returns immediately. At the Vim server the keys are not mapped

```
:map .
```

If `{idvar}` is present, it is taken as the name of a variable and a `{serverid}` for later use with `remote_read()` is stored there.

See also `clientserver` `RemoteReply` .

This function is not available in the `sandbox` .  
 {only available when compiled with the |+clientserver| feature}

**Note:** Any errors will be reported in the server and may mess up the display.

Examples:

```
:echo remote_send("gvim", ":DropAndReply " .. file, "serverid") ..
 \ remote_read(serverid)
```

```
:autocmd NONE RemoteReply *
 \ echo remote_read(expand("<amatch>"))
:echo remote_send("gvim", ":sleep 10 | echo " ..
 \ 'server2client(expand("<client>"), "HELLO")<CR>')
```

Can also be used as a **method** :

```
ServerName()->remote_send(keys)
```

Return type: **String**

`remote_startserver({name})` **remote\_startserver()** E941 E942  
Become the server {name}. {name} must be a non-empty string. This fails if already running as a server, when `v:servername` is not empty.

Can also be used as a **method** :

```
ServerName()->remote_startserver()
```

Return type: **Number**

{only available when compiled with the |+clientserver| feature}

`remove({list}, {idx})` **remove()**  
`remove({list}, {idx}, {end})`

Without {end}: Remove the item at {idx} from **List** {list} and return the item.

With {end}: Remove items from {idx} to {end} (inclusive) and return a **List** with these items. When {idx} points to the same item as {end} a list with one item is returned. When {end} points to an item before {idx} this is an error.

See **list-index** for possible values of {idx} and {end}.

Returns zero on error.

Example:

```
:echo "last item: " .. remove(mylist, -1)
:call remove(mylist, 0, 9)
```

Use **delete()** to remove a file.

Can also be used as a **method** :

```
mylist->remove(idx)
```

Return type: any, depending on {list}

`remove({blob}, {idx})`

`remove({blob}, {idx}, {end})`

Without `{end}`: Remove the byte at `{idx}` from `Blob {blob}` and return the byte.

With `{end}`: Remove bytes from `{idx}` to `{end}` (inclusive) and return a `Blob` with these bytes. When `{idx}` points to the same byte as `{end}` a `Blob` with one byte is returned. When `{end}` points to a byte before `{idx}` this is an error.

Returns zero on error.

Example:

```
:echo "last byte: " .. remove(myblob, -1)
:call remove(mylist, 0, 9)
```

Return type: `Number`

`remove({dict}, {key})`

Remove the entry from `{dict}` with key `{key}` and return it.

Example:

```
:echo "removed " .. remove(dict, "one")
```

If there is no `{key}` in `{dict}` this is an error.

Returns zero on error.

Return type: any, depending on `{dict}`

`rename({from}, {to})`

`rename()`

Rename the file by the name `{from}` to the name `{to}`. This should also work to move files across file systems. The result is a `Number`, which is 0 if the file was renamed successfully, and non-zero when the renaming failed.

**NOTE:** If `{to}` exists it is overwritten without warning.

This function is not available in the `sandbox`.

Can also be used as a `method` :

```
GetOldName()->rename(newname)
```

Return type: `Number`

`repeat({expr}, {count})`

`repeat()`

Repeat `{expr}` `{count}` times and return the concatenated result. Example:

```
:let separator = repeat('-', 80)
```

When `{count}` is zero or negative the result is empty.

When `{expr}` is a `List` or a `Blob` the result is `{expr}` concatenated `{count}` times. Example:

```
:let longlist = repeat(['a', 'b'], 3)
```

Results in `['a', 'b', 'a', 'b', 'a', 'b']`.

Can also be used as a `method` :

```
mylist->repeat(count)
```

Return type: `String`, `Blob` or `list<{type}>` depending on `{expr}`

resolve({filename})

resolve() E655

On MS-Windows, when {filename} is a shortcut (a .lnk file), returns the path the shortcut points to in a simplified form. When {filename} is a symbolic link or junction point, return the full path to the target. If the target of junction is removed, return {filename}.

On Unix, repeat resolving symbolic links in all path components of {filename} and return the simplified result. To cope with link cycles, resolving of symbolic links is stopped after 100 iterations.

On other systems, return the simplified {filename}.

The simplification step is done as by `simplify()`.

`resolve()` keeps a leading path component specifying the current directory (provided the result is still a relative path name) and also keeps a trailing path separator.

Can also be used as a `method` :

```
GetName()->resolve()
```

Return type: `String`

reverse({object})

reverse()

Reverse the order of items in {object}. {object} can be a `List`, a `Blob` or a `String`. For a `List` and a `Blob` the items are reversed in-place and {object} is returned.

For a `String` a new `String` is returned.

Returns zero if {object} is not a `List`, `Blob` or a `String`.

If you want a `List` or `Blob` to remain unmodified make a copy first:

```
:let revlist = reverse(copy(mylist))
```

Can also be used as a `method` :

```
mylist->reverse()
```

Return type: `String`, `Blob` or `list<{type}>` depending on {object}

round({expr})

round()

Round off {expr} to the nearest integral value and return it as a `Float`. If {expr} lies halfway between two integral values, then use the larger one (away from zero).

{expr} must evaluate to a `Float` or a `Number`.

Returns 0.0 if {expr} is not a `Float` or a `Number`.

Examples:

```
echo round(0.456)
```

```
0.0
```

```
echo round(4.5)
```

```
5.0
```

```
echo round(-4.5)
```

```
-5.0
```

Can also be used as a `method` :

`Compute()->round()`

Return type: `Float`

`rubyeval({expr})`

`rubyeval()`

Evaluate Ruby expression `{expr}` and return its result converted to Vim data structures. Numbers, floats and strings are returned as they are (strings are copied though).

Arrays are represented as Vim `List` type.

Hashes are represented as Vim `Dictionary` type.

Other objects are represented as strings resulted from their "Object#to\_s" method.

**Note** that in a `:def` function local variables are not visible to {expr}.`

Can also be used as a `method` :

`GetRubyExpr()->rubyeval()`

Return type: any, depending on `{expr}`

`{only available when compiled with the |+ruby| feature}`

`screenattr({row}, {col})`

`screenattr()`

Like `screenchar()` , but return the attribute. This is a rather arbitrary number that can only be used to compare to the attribute at other positions.

Returns -1 when row or col is out of range.

Can also be used as a `method` :

`GetRow()->screenattr(col)`

Return type: `Number`

`screenchar({row}, {col})`

`screenchar()`

The result is a `Number`, which is the character at position [row, col] on the screen. This works for every possible screen position, also status lines, window separators and the command line. The top left position is row one, column one. The character excludes composing characters. For double-byte encodings it may only be the first byte.

This is mainly to be used for testing.

Returns -1 when row or col is out of range.

Can also be used as a `method` :

`GetRow()->screenchar(col)`

Return type: `Number`

`screenchars({row}, {col})`

`screenchars()`

The result is a `List` of `Numbers`. The first number is the same

as what `screenchar()` returns. Further numbers are composing characters on top of the base character. This is mainly to be used for testing. Returns an empty List when row or col is out of range.

Can also be used as a `method` :  
`GetRow()->screenchars(col)`

Return type: `list<number>` or `list<any>`

`screencol()`

`screencol()`

The result is a Number, which is the current screen column of the cursor. The leftmost column has number 1. This function is mainly used for testing.

**Note:** Always returns the current screen column, thus if used in a command (e.g. `":echo screencol()"`) it will return the column inside the command line, which is 1 when the command is executed. To get the cursor position in the file use one of the following mappings:

```
noremap <expr> GG ":echom " .. screencol() .. "\n"
noremap <silent> GG :echom screencol()<CR>
noremap GG <Cmd>echom screencol()<CR>
```

Return type: `Number`

`screenpos({winid}, {lnum}, {col})`

`screenpos()`

The result is a Dict with the screen position of the text character in window `{winid}` at buffer line `{lnum}` and column `{col}`. `{col}` is a one-based byte index.

The Dict has these members:

```
row screen row
col first screen column
endcol last screen column
curscol cursor screen column
```

If the specified position is not visible, all values are zero. The "endcol" value differs from "col" when the character occupies more than one screen cell. E.g. for a Tab "col" can be 1 and "endcol" can be 8.

The "curscol" value is where the cursor would be placed. For a Tab it would be the same as "endcol", while for a double width character it would be the same as "col".

The `conceal` feature is ignored here, the column numbers are as if '`conceallevel`' is zero. You can set the cursor to the right position and use `screencol()` to get the value with `conceal` taken into account.

If the position is in a closed fold the screen position of the first character is returned, `{col}` is not used.

Returns an empty Dict if `{winid}` is invalid.

Can also be used as a `method` :  
`GetWinid()->screenpos(lnum, col)`

Return type: dict<number> or dict<any>

screenrow()

screenrow()

The result is a Number, which is the current screen row of the cursor. The top line has number one. This function is mainly used for testing. Alternatively you can use `winline()` .

**Note:** Same restrictions as with `screencol()` .

Return type: `Number`

screenstring({row}, {col})

screenstring()

The result is a String that contains the base character and any composing characters at position [row, col] on the screen. This is like `screenchars()` but returning a String with the characters.

This is mainly to be used for testing.

Returns an empty String when row or col is out of range.

Can also be used as a `method` :

`GetRow()->screenstring(col)`

Return type: `String`

search({pattern} [, {flags} [, {stoptline} [, {timeout} [, {skip}]]]])

search()

Search for regexp pattern `{pattern}`. The search starts at the cursor position (you can use `cursor()` to set it).

When a match has been found its line number is returned.

If there is no match a 0 is returned and the cursor doesn't move. No error message is given.

To get the matched string, use `matchbufline()` .

`{flags}` is a String, which can contain these character flags:

'b' search Backward instead of forward

'c' accept a match at the Cursor position

'e' move to the End of the match

'n' do Not move the cursor

'p' return number of matching sub-Pattern (see below)

's' Set the ' mark at the previous location of the cursor

'w' Wrap around the end of the file

'W' don't Wrap around the end of the file

'z' start searching at the cursor column instead of Zero

If neither 'w' or 'W' is given, the **'wrapscan'** option applies.

If the 's' flag is supplied, the ' mark is set, only if the cursor is moved. The 's' flag cannot be combined with the 'n' flag.

'ignorecase', 'smartcase' and 'magic' are used.

When the 'z' flag is not given, forward searching always starts in column zero and then matches before the cursor are skipped. When the 'c' flag is present in 'cpo' the next search starts after the match. Without the 'c' flag the next search starts one column after the start of the match. This matters for overlapping matches. See `cpo-c` . You can also insert "\ze" to change where the match ends, see `/\ze` .

When searching backwards and the 'z' flag is given then the search starts in column zero, thus no match in the current line will be found (unless wrapping around the end of the file).

When the `{stopline}` argument is given then the search stops after searching this line. This is useful to restrict the search to a range of lines. Examples:

```
let match = search('(', 'b', line("w0"))
let end = search('END', '', line("w$"))
```

When `{stopline}` is used and it is not zero this also implies that the search does not wrap around the end of the file. A zero value is equal to not giving the argument.

E1285 E1286 E1287 E1288 E1289

When the `{timeout}` argument is given the search stops when more than this many milliseconds have passed. Thus when `{timeout}` is 500 the search stops after half a second. The value must not be negative. A zero value is like not giving the argument.

**Note:** the timeout is only considered when searching, not while evaluating the `{skip}` expression.  
{only available when compiled with the `|+retime|` feature}

If the `{skip}` expression is given it is evaluated with the cursor positioned on the start of a match. If it evaluates to non-zero this match is skipped. This can be used, for example, to skip a match in a comment or a string.

`{skip}` can be a string, which is evaluated as an expression, a function reference or a lambda.

When `{skip}` is omitted or empty, every match is accepted. When evaluating `{skip}` causes an error the search is aborted and -1 returned.

`search()-sub-match`

With the 'p' flag the returned value is one more than the first sub-match in `\(\)`. One if none of them matched but the whole pattern did match.

To get the column number too use `searchpos()` .

The cursor will be positioned at the match, unless the 'n' flag is used.

Example (goes over all files in the argument list):

```
:let n = 1
```

```

:while n <= argc() " loop over all files in arglist
: exe "argument " .. n
: " start at the last char in the file and wrap for the
: " first search to find match at start of file
: normal G$
: let flags = "w"
: while search("foo", flags) > 0
: s/foo/bar/g
: let flags = "W"
: endwhile
: update " write the file if modified
: let n = n + 1
:endwhile

```

Example for using some flags:

```
:echo search('\<if\|\(else\)\|\(endif\)', 'ncpe')
```

This will search for the keywords "if", "else", and "endif" under or after the cursor. Because of the 'p' flag, it returns 1, 2, or 3 depending on which keyword is found, or 0 if the search fails. With the cursor on the first word of the line:

```
if (foo == 0) | let foo = foo + 1 | endif
```

the function returns 1. Without the 'c' flag, the function finds the "endif" and returns 3. The same thing happens without the 'e' flag if the cursor is on the "f" of "if". The 'n' flag tells the function not to move the cursor.

Can also be used as a [method](#) :

```
GetPattern()->search()
```

Return type: [Number](#)

`searchcount([options])` [searchcount\(\)](#)

Get or update the last search count, like what is displayed without the "S" flag in '[shortmess](#)'. This works even if '[shortmess](#)' does contain the "S" flag.

This returns a [Dictionary](#) . The dictionary is empty if the previous pattern was not set and "pattern" was not specified.

key	type	meaning
current	<a href="#">Number</a>	current position of match; 0 if the cursor position is before the first match
exact_match	<a href="#">Boolean</a>	1 if "current" is matched on "pos", otherwise 0
total	<a href="#">Number</a>	total count of matches found
incomplete	<a href="#">Number</a>	0: search was fully completed 1: recomputing was timed out 2: max count exceeded

For `{options}` see further down.

To get the last search count when `n` or `N` was pressed, call this function with ``recompute: 0``. This sometimes returns wrong information because `n` and `N`'s maximum count is 99. If it exceeded 99 the result must be max count + 1 (100). If you want to get correct information, specify ``recompute: 1``:

```

" result == maxcount + 1 (100) when many matches
let result = searchcount({recompute: 0})

" Below returns correct result (recompute defaults
" to 1)
let result = searchcount()

```

The function is useful to add the count to **'statusline'**:

```

function! LastSearchCount() abort
 let result = searchcount({recompute: 0})
 if empty(result)
 return ''
 endif
 if result.incomplete ==# 1 " timed out
 return printf(' /%s [?/??]', @/)
 elseif result.incomplete ==# 2 " max count exceeded
 if result.total > result.maxcount &&
 \ result.current > result.maxcount
 return printf(' /%s [>%d/>%d]', @/,
 \ result.current, result.total)
 elseif result.total > result.maxcount
 return printf(' /%s [%d/>%d]', @/,
 \ result.current, result.total)
 endif
 endif
 return printf(' /%s [%d/%d]', @/,
 \ result.current, result.total)
endfunction
let &statusline .= '%{LastSearchCount()}'

" Or if you want to show the count only when
" 'hlsearch' was on
" let &statusline .=
" \ '%{v:hlsearch ? LastSearchCount() : ""}'

```

You can also update the search count, which can be useful in a `CursorMoved` or `CursorMovedI` autocommand:

```

autocmd CursorMoved,CursorMovedI *
 \ let s:searchcount_timer = timer_start(
 \ 200, function('s:update_searchcount'))
function! s:update_searchcount(timer) abort
 if a:timer ==# s:searchcount_timer
 call searchcount({
 \ recompute: 1, maxcount: 0, timeout: 100})
 redrawstatus
 endif
endfunction

```

This can also be used to count matched texts with specified pattern in the current buffer using "pattern":

```
" Count '\<foo\>' in this buffer
" (Note that it also updates search count)
let result = searchcount(#{pattern: '\<foo\>'})

" To restore old search count by old pattern,
" search again
call searchcount()
```

{options} must be a [Dictionary](#) . It can contain:

key	type	meaning
recompute	Boolean	if <code>TRUE</code> , recompute the count like <code>n</code> or <code>N</code> was executed. otherwise returns the last computed result (when <code>n</code> or <code>N</code> was used when "S" is not in ' <a href="#">shortmess</a> ', or this function was called). (default: <code>TRUE</code> )
pattern	String	recompute if this was given and different with <code>@/</code> . this works as same as the below command is executed before calling this function <code>let @/ = pattern</code> (default: <code>@/</code> )
timeout	Number	0 or negative number is no timeout. timeout milliseconds for recomputing the result (default: 0)
maxcount	Number	0 or negative number is no limit. max count of matched text while recomputing the result. if search exceeded total count, "total" value becomes <code>`maxcount + 1`</code> (default: 99)
pos	List	<code>`[lnum, col, off]`</code> value when recomputing the result. this changes "current" result value. see <a href="#">cursor()</a> , <a href="#">getpos()</a> (default: cursor's position)

Can also be used as a [method](#) :

```
GetSearchOpts()->searchcount()
```

Return type: dict<number>

```
searchdecl({name} [, {global} [, {thisblock}]])
```

```
searchdecl()
```

Search for the declaration of `{name}`.

With a non-zero `{global}` argument it works like `gD`, find first match in the file. Otherwise it works like `gd`, find first match in the function.

With a non-zero `{thisblock}` argument matches in a `{}` block that ends before the cursor position are ignored. Avoids finding variable declarations only valid in another scope.

Moves the cursor to the found match.

Returns zero for success, non-zero for failure.

Example:

```
if searchdecl('myvar') == 0
 echo getline('.')
endif
```

Can also be used as a `method` :

```
GetName()->searchdecl()
```

Return type: `Number`

```
searchpair({start}, {middle}, {end} [, {flags} [, {skip}
 [, {stoplevel} [, {timeout}]]]])
```

Search for the match of a nested start-end pair. This can be used to find the "endif" that matches an "if", while other if/endif pairs in between are ignored.

The search starts at the cursor. The default is to search forward, include 'b' in `{flags}` to search backward.

If a match is found, the cursor is positioned at it and the line number is returned. If no match is found 0 or -1 is returned and the cursor doesn't move. No error message is given.

`{start}`, `{middle}` and `{end}` are patterns, see `pattern`. They must not contain `\( \)` pairs. Use of `\%( \)` is allowed. When `{middle}` is not empty, it is found when searching from either direction, but only when not in a nested start-end pair. A typical use is:

```
searchpair('\<if>', '\<else>', '\<endif>')
```

By leaving `{middle}` empty the "else" is skipped.

`{flags}` 'b', 'c', 'n', 's', 'w' and 'W' are used like with `search()`. Additionally:

'r' Repeat until no more matches found; will find the outer pair. Implies the 'W' flag.

'm' Return number of matches instead of line number with the match; will be > 1 when 'r' is used.

**Note:** it's nearly always a good idea to use the 'W' flag, to avoid wrapping around the end of the file.

When a match for `{start}`, `{middle}` or `{end}` is found, the `{skip}` expression is evaluated with the cursor positioned on

the start of the match. It should return non-zero if this match is to be skipped. E.g., because it is inside a comment or a string.

When `{skip}` is omitted or empty, every match is accepted.

When evaluating `{skip}` causes an error the search is aborted and -1 returned.

`{skip}` can be a string, a lambda, a funcref or a partial. Anything else makes the function fail.

In a `:def` function when the `{skip}` argument is a string constant it is compiled into instructions.

For `{stopline}` and `{timeout}` see `search()` .

The value of `'ignorecase'` is used. `'magic'` is ignored, the patterns are used like it's on.

The search starts exactly at the cursor. A match with `{start}`, `{middle}` or `{end}` at the next character, in the direction of searching, is the first one found. Example:

```
if 1
 if 2
 endif 2
 endif 1
```

When starting at the "if 2", with the cursor on the "i", and searching forwards, the "endif 2" is found. When starting on the character just before the "if 2", the "endif 1" will be found. That's because the "if 2" will be found first, and then this is considered to be a nested if/endif from "if 2" to "endif 2".

When searching backwards and `{end}` is more than one character, it may be useful to put `"\zs"` at the end of the pattern, so that when the cursor is inside a match with the end it finds the matching start.

Example, to find the "endif" command in a Vim script:

```
:echo searchpair('\<if\>', '\<el\%[seif]\>', '\<en\%[dif]\>', 'W',
 \ 'getline(".") =~ "^\\s*\\\"")
```

The cursor must be at or after the "if" for which a match is to be found. **Note** that single-quote strings are used to avoid having to double the backslashes. The skip expression only catches comments at the start of a line, not after a command. Also, a word "en" or "if" halfway a line is considered a match.

Another example, to search for the matching "{ of a }":

```
:echo searchpair('{', '', '}', 'bW')
```

This works when the cursor is at or before the "}" for which a match is to be found. To reject matches that syntax highlighting recognized as strings:

```
:echo searchpair('{', '', '}', 'bW',
```

```
\ 'synIDattr(synID(line("."), col("."), 0), "name") =~? "string")
```

Return type: `Number`

```
searchpairpos({start}, {middle}, {end} [, {flags} [, {skip}
 [, {stoptime} [, {timeout}]]]])
```

Same as `searchpair()`, but returns a `List` with the line and column position of the match. The first element of the `List` is the line number and the second element is the byte index of the column position of the match. If no match is found, returns `[0, 0]`.

```
:let [lnum,col] = searchpairpos('{', '|', '|', 'n')
```

See `match-parens` for a bigger and more useful example.

Return type: `list<number>`

```
searchpos({pattern} [, {flags} [, {stoptime} [, {timeout} [, {skip}]]]])
```

Same as `search()`, but returns a `List` with the line and column position of the match. The first element of the `List` is the line number and the second element is the byte index of the column position of the match. If no match is found, returns `[0, 0]`.

Example:

```
:let [lnum, col] = searchpos('mypattern', 'n')
```

When the 'p' flag is given then there is an extra item with the sub-pattern match number `search()-sub-match`. Example:

```
:let [lnum, col, submatch] = searchpos('\(\l\)\|\(\u\)', 'np')
```

In this example "submatch" is 2 when a lowercase letter is found `/\l`, 3 when an uppercase letter is found `/\u`.

Can also be used as a `method` :

```
GetPattern()->searchpos()
```

Return type: `list<number>`

```
server2client({clientid}, {string})
```

Send a reply string to `{clientid}`. The most recent `{clientid}` that sent a string can be retrieved with `expand("<client>")`.  
{only available when compiled with the `|+clientserver|` feature}  
Returns zero for success, -1 for failure.

**Note:**

This id has to be stored before the next command can be received. I.e. before returning from the received command and before calling any commands that waits for input.

See also `clientserver`.

Example:

```
:echo server2client(expand("<client>"), "HELLO")
```

Can also be used as a `method` :

```
GetClientId()->server2client(string)
```

Return type: `Number`

`serverlist()`

`serverlist()`

Return a list of available server names, one per line. When there are no servers or the information is not available an empty string is returned. See also `clientserver` .  
{only available when compiled with the |+clientserver| feature}  
Example:

```
:echo serverlist()
```

Return type: `String`

`setbufline({buf}, {lnum}, {text})`

`setbufline()`

Set line `{lnum}` to `{text}` in buffer `{buf}`. This works like `setline()` for the specified buffer.

This function works only for loaded buffers. First call `bufload()` if needed.

To insert lines use `appendbufline()` .  
Any text properties in `{lnum}` are cleared.

`{text}` can be a string to set one line, or a List of strings to set multiple lines. If the List extends below the last line then those lines are added. If the List is empty then nothing is changed and zero is returned.

For the use of `{buf}`, see `bufname()` above.

`{lnum}` is used like with `setline()` .  
Use "\$" to refer to the last line in buffer `{buf}`.  
When `{lnum}` is just below the last line the `{text}` will be added below the last line.

When `{buf}` is not a valid buffer, the buffer is not loaded or `{lnum}` is not valid then 1 is returned. In `Vim9` script an error is given.  
On success 0 is returned.

Can also be used as a `method` , the base is passed as the third argument:

```
GetText()->setbufline(buf, lnum)
```

Return type: `Number`

`setbufvar({buf}, {varname}, {val})`

`setbufvar()`

Set option or local variable `{varname}` in buffer `{buf}` to `{val}`.

This also works for a global or local window option, but it doesn't work for a global or local window variable. For a local window option the global value is unchanged. For the use of `{buf}`, see `bufname()` above. The `{varname}` argument is a string. **Note** that the variable name without "b:" must be used. Examples:

```
:call setbufvar(1, "&mod", 1)
:call setbufvar("todo", "myvar", "foobar")
```

This function is not available in the `sandbox` .

Can also be used as a `method` , the base is passed as the third argument:

```
GetValue()->setbufvar(buf, varname)
```

Return type: `Number`

`setcellwidths({list})` `setcellwidths()`

Specify overrides for cell widths of character ranges. This tells Vim how wide characters are when displayed in the terminal, counted in screen cells. The values override `'ambiwidth'`. Example:

```
call setcellwidths([
 \ [0x111, 0x111, 1],
 \ [0x2194, 0x2199, 2],
 \])
```

The `{list}` argument is a List of Lists with each three numbers: `[{low}, {high}, {width}]`. `E1109` `E1110`  
`{low}` and `{high}` can be the same, in which case this refers to one character. Otherwise it is the range of characters from `{low}` to `{high}` (inclusive). `E1111` `E1114`  
Only characters with value `0x80` and higher can be used.

`{width}` must be either 1 or 2, indicating the character width in screen cells. `E1112`

An error is given if the argument is invalid, also when a range overlaps with another. `E1113`

If the new value causes `'fillchars'` or `'listchars'` to become invalid it is rejected and an error is given.

To clear the overrides pass an empty `{list}`:

```
setcellwidths([]);
```

You can use the script `$VIMRUNTIME/tools/emoji_list.vim` to see the effect for known emoji characters. Move the cursor through the text to check if the cell widths of your terminal match with what Vim knows about each emoji. If it doesn't look right you need to adjust the `{list}` argument.

Return type: `Number`

`setcharpos({expr}, {list})` `setcharpos()`  
Same as `setpos()` but uses the specified column number as the character index instead of the byte index in the line.

Example:

With the text "␣␣␣␣" in line 8:

```
 call setcharpos('.', [0, 8, 4, 0])
positions the cursor on the fourth character '␣'.
 call setpos('.', [0, 8, 4, 0])
positions the cursor on the second character '␣'.
```

Can also be used as a `method` :

```
GetPosition()->setcharpos('.')
```

Return type: `Number`

`setcharsearch({dict})` `setcharsearch()`  
Set the current character search information to `{dict}`, which contains one or more of the following entries:

<code>char</code>	character which will be used for a subsequent <code>,</code> or <code>;</code> command; an empty string clears the character search
<code>forward</code>	direction of character search; 1 for forward, 0 for backward
<code>until</code>	type of character search; 1 for a <code>t</code> or <code>T</code> character search, 0 for an <code>f</code> or <code>F</code> character search

This can be useful to save/restore a user's character search from a script:

```
:let prevsearch = getcharsearch()
:" Perform a command which clobbers user's search
:call setcharsearch(prevsearch)
```

Also see `getcharsearch()` .

Can also be used as a `method` :

```
SavedSearch()->setcharsearch()
```

Return type: `dict<any>`

`setcmdline({str} [, {pos}])` `setcmdline()`  
Set the command line to `{str}` and set the cursor position to `{pos}`.  
If `{pos}` is omitted, the cursor is positioned after the text.  
Returns 0 when successful, 1 when not editing the command line.

Can also be used as a `method` :

```
GetText()->setcmdline()
```

Return type: `Number`

`setcmdpos({pos})`

`setcmdpos()`

Set the cursor position in the command line to byte position `{pos}`. The first position is 1.

Use `getcmdpos()` to obtain the current position.

Only works while editing the command line, thus you must use

`c_CTRL-\_e`, `c_CTRL-R_=` or `c_CTRL-R_CTRL-R` with '='. For `c_CTRL-\_e` and `c_CTRL-R_CTRL-R` with '=' the position is set after the command line is set to the expression. For `c_CTRL-R_=` it is set after evaluating the expression but before inserting the resulting text.

When the number is too big the cursor is put at the end of the line. A number smaller than one has undefined results.

Returns 0 when successful, 1 when not editing the command line.

Can also be used as a `method` :

`GetPos()->setcmdpos()`

Return type: `Number`

`setcursorcharpos({lnum}, {col} [, {off}])`

`setcursorcharpos()`

`setcursorcharpos({list})`

Same as `cursor()` but uses the specified column number as the character index instead of the byte index in the line.

Example:

With the text "␣␣␣␣" in line 4:

`call setcursorcharpos(4, 3)`

positions the cursor on the third character '␣'.

`call cursor(4, 3)`

positions the cursor on the first character '␣'.

Can also be used as a `method` :

`GetCursorPos()->setcursorcharpos()`

Return type: `Number`

`setenv({name}, {val})`

`setenv()`

Set environment variable `{name}` to `{val}`. Example:

`call setenv('HOME', '/home/myhome')`

When `{val}` is `v:null` the environment variable is deleted.

See also `expr-env` .

Can also be used as a `method` , the base is passed as the second argument:

`GetPath()->setenv('PATH')`

Return type: `Number`

`setfperm({fname}, {mode})` `setfperm()` `chmod`  
Set the file permissions for `{fname}` to `{mode}`.  
`{mode}` must be a string with 9 characters. It is of the form "rwxrwxrwx", where each group of "rwx" flags represent, in turn, the permissions of the owner of the file, the group the file belongs to, and other users. A '-' character means the permission is off, any other character means on. Multi-byte characters are not supported.

For example "rw-r-----" means read-write for the user, readable by the group, not accessible by others. "xx-x-----" would do the same thing.

Returns non-zero for success, zero for failure.

Can also be used as a `method` :  
`GetFilename()->setfperm(mode)`

To read permissions see `getfperm()`.

Return type: `Number`

`setline({lnum}, {text})` `setline()`  
Set line `{lnum}` of the current buffer to `{text}`. To insert lines use `append()`. To set lines in another buffer use `setbufline()`.  
Any text properties in `{lnum}` are cleared. See `text-prop-cleared`

`{lnum}` is used like with `getline()`.

When `{lnum}` is just below the last line the `{text}` will be added below the last line.

`{text}` can be any type or a List of any type, each item is converted to a String. When `{text}` is an empty List then nothing is changed and FALSE is returned.

If this succeeds, FALSE is returned. If this fails (most likely because `{lnum}` is invalid) TRUE is returned.

In `Vim9` script an error is given if `{lnum}` is invalid.

Example:

```
:call setline(5, strftime("%c"))
```

When `{text}` is a `List` then line `{lnum}` and following lines will be set to the items in the list. Example:

```
:call setline(5, ['aaa', 'bbb', 'ccc'])
```

This is equivalent to:

```
:for [n, l] in [[5, 'aaa'], [6, 'bbb'], [7, 'ccc']]
: call setline(n, l)
:endfor
```

**Note:** The '[' and ']' marks are not set.

Can also be used as a `method` , the base is passed as the second argument:

```
GetText()->setline(lnum)
```

Return type: `Number`

`setloclist({nr}, {list} [, {action} [, {what}]])` `setloclist()`  
Create or replace or add to the location list for window `{nr}`.  
`{nr}` can be the window number or the `window-ID` .  
When `{nr}` is zero the current window is used.

For a location list window, the displayed location list is modified. For an invalid window number `{nr}`, -1 is returned. Otherwise, same as `setqflist()` .  
Also see `location-list` .

For `{action}` see `setqflist-action` .

If the optional `{what}` dictionary argument is supplied, then only the items listed in `{what}` are set. Refer to `setqflist()` for the list of supported keys in `{what}`.

Can also be used as a `method` , the base is passed as the second argument:

```
GetLoclist()->setloclist(winnr)
```

Return type: `Number`

`setmatches({list} [, {win}])` `setmatches()`  
Restores a list of matches saved by `getmatches()` for the current window. Returns 0 if successful, otherwise -1. All current matches are cleared before the list is restored. See example for `getmatches()` .  
If `{win}` is specified, use the window with this number or window ID instead of the current window.

Can also be used as a `method` :

```
GetMatches()->setmatches()
```

Return type: `Number`

`setpos({expr}, {list})` `setpos()`  
Set the position for String `{expr}`. Possible values:  
    .           the cursor  
    'x          mark x

`{list}` must be a `List` with four or five numbers:  
    [bufnum, lnum, col, off]  
    [bufnum, lnum, col, off, curswant]

"bufnum" is the buffer number. Zero can be used for the current buffer. When setting an uppercase mark "bufnum" is used for the mark position. For other marks it specifies the buffer to set the mark in. You can use the `bufnr()` function to turn a file name into a buffer number. For setting the cursor and the ' mark "bufnum" is ignored, since these are associated with a window, not a buffer. Does not change the jumplist.

"lnum" and "col" are the position in the buffer. The first column is 1. Use a zero "lnum" to delete a mark. If "col" is smaller than 1 then 1 is used. To use the character count instead of the byte count, use `setcharpos()` .

The "off" number is only used when **'virtualedit'** is set. Then it is the offset in screen columns from the start of the character. E.g., a position within a `<Tab>` or after the last character.

The "curswant" number is only used when setting the cursor position. It sets the preferred column for when moving the cursor vertically. When the "curswant" number is missing the preferred column is not set. When it is present and setting a mark position it is not used.

**Note** that for '< and '> changing the line number may result in the marks to be effectively be swapped, so that '< is always before '>.

Returns 0 when the position could be set, -1 otherwise. An error message is given if `{expr}` is invalid.

Also see `setcharpos()` , `getpos()` and `getcurpos()` .

This does not restore the preferred column for moving vertically; if you set the cursor position with this, `j` and `k` motions will jump to previous columns! Use `cursor()` to also set the preferred column. Also see the "curswant" key in `winrestview()` .

Can also be used as a **method** :  
`GetPosition()->setpos('.')`

Return type: **Number**

`setqflist({list} [, {action} [, {what}]]])` `setqflist()`  
Create or replace or add to the quickfix list.

If the optional `{what}` dictionary argument is supplied, then only the items listed in `{what}` are set. The first `{list}` argument is ignored. See below for the supported items in `{what}`.

## setqflist-what

When `{what}` is not present, the items in `{list}` are used. Each item must be a dictionary. Non-dictionary items in `{list}` are ignored. Each dictionary item can contain the following entries:

<code>bufnr</code>	buffer number; must be the number of a valid buffer
<code>filename</code>	name of a file; only used when "bufnr" is not present or it is invalid.
<code>module</code>	name of a module; if given it will be used in quickfix error window instead of the filename.
<code>lnum</code>	line number in the file
<code>end_lnum</code>	end of lines, if the item spans multiple lines
<code>pattern</code>	search pattern used to locate the error
<code>col</code>	column number
<code>vcoll</code>	when non-zero: "col" is visual column when zero: "col" is byte index
<code>end_col</code>	end column, if the item spans multiple columns
<code>nr</code>	error number
<code>text</code>	description of the error
<code>type</code>	single-character error type, 'E', 'W', etc.
<code>valid</code>	recognized error message
<code>user_data</code>	custom data associated with the item, can be any type.

The "col", "vcoll", "nr", "type" and "text" entries are optional. Either "lnum" or "pattern" entry can be used to locate a matching error line.

If the "filename" and "bufnr" entries are not present or neither the "lnum" or "pattern" entries are present, then the item will not be handled as an error line.

If both "pattern" and "lnum" are present then "pattern" will be used.

If the "valid" entry is not supplied, then the valid flag is set when "bufnr" is a valid buffer or "filename" exists.

If you supply an empty `{list}`, the quickfix list will be cleared.

**Note** that the list is not exactly the same as what `setqflist()` returns.

`{action}` values: [setqflist-action](#) E927

'a' The items from `{list}` are added to the existing quickfix list. If there is no existing list, then a new list is created.

'r' The items from the current quickfix list are replaced with the items from `{list}`. This can also be used to clear the list:

```
:call setqflist([], 'r')
```

'u' Like 'r', but tries to preserve the current selection in the quickfix list.

'f' All the quickfix lists in the quickfix stack are

freed.

If `{action}` is not present or is set to ' ', then a new list is created. The new quickfix list is added after the current quickfix list in the stack and all the following lists are freed. To add a new quickfix list at the end of the stack, set "nr" in `{what}` to "\$".

The following items can be specified in dictionary `{what}`:

context	quickfix list context. See <a href="#">quickfix-context</a>
efm	errorformat to use when parsing text from "lines". If this is not present, then the <b>'errorformat'</b> option value is used. See <a href="#">quickfix-parse</a>
id	quickfix list identifier <a href="#">quickfix-ID</a>
idx	index of the current entry in the quickfix list specified by 'id' or 'nr'. If set to '\$', then the last entry in the list is set as the current entry. See <a href="#">quickfix-index</a>
items	list of quickfix entries. Same as the <code>{list}</code> argument.
lines	use <b>'errorformat'</b> to parse a list of lines and add the resulting entries to the quickfix list <code>{nr}</code> or <code>{id}</code> . Only a <code>List</code> value is supported. See <a href="#">quickfix-parse</a>
nr	list number in the quickfix stack; zero means the current quickfix list and "\$" means the last quickfix list.
quickfixtextfunc	function to get the text to display in the quickfix window. The value can be the name of a function or a funcref or a lambda. Refer to <a href="#">quickfix-window-function</a> for an explanation of how to write the function and an example.
title	quickfix list title text. See <a href="#">quickfix-title</a>

Unsupported keys in `{what}` are ignored.

If the "nr" item is not present, then the current quickfix list is modified. When creating a new quickfix list, "nr" can be set to a value one greater than the quickfix stack size.

When modifying a quickfix list, to guarantee that the correct list is modified, "id" should be used instead of "nr" to specify the list.

Examples (See also [setqflist-examples](#)):

```
:call setqflist([], 'r', {'title': 'My search'})
:call setqflist([], 'r', {'nr': 2, 'title': 'Errors'})
:call setqflist([], 'a', {'id':qfid, 'lines':["F1:10:L10"]})
```

Returns zero for success, -1 for failure.

This function can be used to create a quickfix list independent of the **'errorformat'** setting. Use a command like ``:cc 1`` to jump to the first position.

Can also be used as a [method](#) , the base is passed as the second argument:

```
GetErrorlist()->setqflist()
```

Return type: [Number](#)

`setreg({regname}, {value} [, {options}])` [setreg\(\)](#)

Set the register `{regname}` to `{value}`.  
If `{regname}` is "" or "@", the unnamed register "" is used.  
The `{regname}` argument is a string. In [Vim9-script](#) `{regname}` must be one character.

`{value}` may be any value returned by [getreg\(\)](#) or [getreginfo\(\)](#) , including a [List](#) or [Dict](#) .  
If `{options}` contains "a" or `{regname}` is upper case, then the value is appended.

`{options}` can also contain a register type specification:

```
"c" or "v" characterwise mode
"l" or "V" linewise mode
"b" or "<CTRL-V>" blockwise-visual mode
```

If a number immediately follows "b" or "<CTRL-V>" then this is used as the width of the selection - if it is not specified then the width of the block is set to the number of characters in the longest line (counting a `<Tab>` as 1 character).

If `{options}` contains no register settings, then the default is to use character mode unless `{value}` ends in a `<NL>` for string `{value}` and linewise mode for list `{value}`. Blockwise mode is never selected automatically.

Returns zero for success, non-zero for failure.

[E883](#)

**Note:** you may not use [List](#) containing more than one item to set search and expression registers. Lists containing no items act like empty strings.

Examples:

```
:call setreg(v:register, @*)
:call setreg('*', @%, 'ac')
:call setreg('a', "1\n2\n3", 'b5')
:call setreg('"'', { 'points_to': 'a'})
```

This example shows using the functions to save and restore a register:

```
:let var_a = getreginfo()
:call setreg('a', var_a)
```

or:

```
:let var_a = getreg('a', 1, 1)
:let var_amode = getregtype('a')
.....
:call setreg('a', var_a, var_amode)
```

**Note:** you may not reliably restore register value

without using the third argument to `getreg()` as without it newlines are represented as newlines AND Nul bytes are represented as newlines as well, see [NL-used-for-Nul](#) .

You can also change the type of a register by appending nothing:

```
:call setreg('a', '', 'al')
```

Can also be used as a [method](#) , the base is passed as the second argument:

```
GetText()->setreg('a')
```

Return type: [Number](#)

`settabvar({tabnr}, {varname}, {val})` [settabvar\(\)](#)  
Set tab-local variable `{varname}` to `{val}` in tab page `{tabnr}`.  
`t:var`

The `{varname}` argument is a string.

**Note** that autocommands are blocked, side effects may not be triggered, e.g. when setting `'filetype'`.

**Note** that the variable name without "t:" must be used.

Tabs are numbered starting with one.

This function is not available in the [sandbox](#) .

Can also be used as a [method](#) , the base is passed as the third argument:

```
GetValue()->settabvar(tab, name)
```

Return type: [Number](#)

`settabwinvar({tabnr}, {winnr}, {varname}, {val})` [settabwinvar\(\)](#)  
Set option or local variable `{varname}` in window `{winnr}` to `{val}`.  
Tabs are numbered starting with one. For the current tabpage use `setwinvar()` .

`{winnr}` can be the window number or the [window-ID](#) .

When `{winnr}` is zero the current window is used.

**Note** that autocommands are blocked, side effects may not be triggered, e.g. when setting `'filetype'` or `'syntax'`.

This also works for a global or local buffer option, but it doesn't work for a global or local buffer variable.

For a local buffer option the global value is unchanged.

**Note** that the variable name without "w:" must be used.

Examples:

```
:call settabwinvar(1, 1, "&list", 0)
:call settabwinvar(3, 2, "myvar", "foobar")
```

This function is not available in the [sandbox](#) .

Can also be used as a [method](#) , the base is passed as the fourth argument:

```
GetValue()->settabwinvar(tab, winnr, name)
```

Return type: [Number](#)

`settagstack({nr}, {dict} [, {action}])` [settagstack\(\)](#)

Modify the tag stack of the window `{nr}` using `{dict}`.  
`{nr}` can be the window number or the [window-ID](#) .

For a list of supported items in `{dict}`, refer to [gettagstack\(\)](#) . "curidx" takes effect before changing the tag stack.

[E962](#)

How the tag stack is modified depends on the `{action}` argument:

- If `{action}` is not present or is set to 'r', then the tag stack is replaced.
- If `{action}` is set to 'a', then new entries from `{dict}` are pushed (added) onto the tag stack.
- If `{action}` is set to 't', then all the entries from the current entry in the tag stack or "curidx" in `{dict}` are removed and then new entries are pushed to the stack.

The current index is set to one after the length of the tag stack after the modification.

Returns zero for success, -1 for failure.

Examples (for more examples see [tagstack-examples](#) ):

Empty the tag stack of window 3:  
`call settagstack(3, {'items' : []})`

Save and restore the tag stack:  
`let stack = gettagstack(1003)`  
`" do something else`  
`call settagstack(1003, stack)`  
`unlet stack`

Can also be used as a [method](#) , the base is passed as the second argument:

`GetStack()->settagstack(winnr)`

Return type: [Number](#)

`setwinvar({winnr}, {varname}, {val})` [setwinvar\(\)](#)

Like [settabwinvar\(\)](#) for the current tab page.

Examples:

`:call setwinvar(1, "&list", 0)`  
`:call setwinvar(2, "myvar", "foobar")`

Can also be used as a [method](#) , the base is passed as the third argument:

`GetValue()->setwinvar(winnr, name)`

Return type: [Number](#)

sha256({string}) sha256()  
Returns a String with 64 hex characters, which is the SHA256 checksum of {string}.

Can also be used as a `method` :  
`GetText()->sha256()`

Return type: `String`

{only available when compiled with the |+cryptv| feature}

shellescape({string} [, {special}]) shellescape()

Escape {string} for use as a shell command argument. When the '**shell**' contains powershell (MS-Windows) or pwsh (MS-Windows, Linux, and macOS) then it will enclose {string} in single quotes and will double up all internal single quotes.

On MS-Windows, when '**shellslash**' is not set, it will enclose {string} in double quotes and double all double quotes within {string}.

Otherwise it will enclose {string} in single quotes and replace all '"' with "'\"'

The {special} argument adds additional escaping of keywords used in Vim commands. When it is not omitted and a non-zero number or a non-empty String ( `non-zero-arg` ), then special items such as "!", "%", "#", and "<word>" (as listed in `expand()` ) will be preceded by a backslash.

This backslash will be removed again by the `:!` command.

The "!" character will be escaped (again with a `non-zero-arg` {special}) when '**shell**' contains "csh" in the tail. That is because for csh and tcsh "!" is used for history replacement even when inside single quotes.

With a `non-zero-arg` {special} the <NL> character is also escaped. When '**shell**' containing "csh" in the tail it's escaped a second time.

The "\" character will be escaped when '**shell**' contains "fish" in the tail. That is because for fish "\" is used as an escape character inside single quotes.

Example of use with a `:!` command:

```
:exe '!dir ' .. shellescape(expand('<file>'), 1)
```

This results in a directory listing for the file under the cursor. Example of use with `system()` :

```
:call system("chmod +w -- " .. shellescape(expand("%"))))
```

See also `::S` .

Can also be used as a `method` :

```
GetCommand()->shellescape()
```

Return type: [String](#)

`shiftwidth([{col}])` [shiftwidth\(\)](#)

Returns the effective value of **'shiftwidth'**. This is the **'shiftwidth'** value unless it is zero, in which case it is the **'tabstop'** value. This function was introduced with patch 7.3.694 in 2012, everybody should have it by now (however it did not allow for the optional `{col}` argument until 8.1.542).

When there is one argument `{col}` this is used as column number for which to return the **'shiftwidth'** value. This matters for the **'vartabstop'** feature. If the **'vartabstop'** setting is enabled and no `{col}` argument is given, column 1 will be assumed.

Can also be used as a [method](#) :  
`GetColumn()->shiftwidth()`

Return type: [Number](#)

`sign_` functions are documented here: [sign-functions-details](#)

`simplify({filename})` [simplify\(\)](#)

Simplify the file name as much as possible without changing the meaning. Shortcuts (on MS-Windows) or symbolic links (on Unix) are not resolved. If the first path component in `{filename}` designates the current directory, this will be valid for the result as well. A trailing path separator is not removed either. On Unix `//path` is unchanged, but `///path` is simplified to `/path` (this follows the Posix standard).

Example:

```
simplify("./dir/../../file/") == "./file/"
```

**Note:** The combination `dir/..` is only removed if `dir` is a searchable directory or does not exist. On Unix, it is also removed when `dir` is a symbolic link within the same directory. In order to resolve all the involved symbolic links before simplifying the path name, use [resolve\(\)](#) .

Can also be used as a [method](#) :  
`GetName()->simplify()`

Return type: [String](#)

`sin({expr})` [sin\(\)](#)

Return the sine of `{expr}`, measured in radians, as a [Float](#) .  
`{expr}` must evaluate to a [Float](#) or a [Number](#) .

Returns 0.0 if `{expr}` is not a [Float](#) or a [Number](#) .

Examples:

```
:echo sin(100)
-0.506366
```

```
:echo sin(-4.01)
0.763301
```

Can also be used as a `method` :  
`Compute()->sin()`

Return type: `Float`

`sinh({expr})`

`sinh()`

Return the hyperbolic sine of `{expr}` as a `Float` in the range `[-inf, inf]`.

`{expr}` must evaluate to a `Float` or a `Number` .

Returns `0.0` if `{expr}` is not a `Float` or a `Number` .

Examples:

```
:echo sinh(0.5)
0.521095
:echo sinh(-0.9)
-1.026517
```

Can also be used as a `method` :  
`Compute()->sinh()`

Return type: `Float`

`slice({expr}, {start} [, {end}])`

`slice()`

Similar to using a `slice` "expr[start : end]", but "end" is used exclusive. And for a string the indexes are used as character indexes instead of byte indexes, like in `vim9script` . Also, composing characters are treated as a part of the preceding base character.

When `{end}` is omitted the slice continues to the last item.

When `{end}` is `-1` the last item is omitted.

Returns an empty value if `{start}` or `{end}` are invalid.

Can also be used as a `method` :  
`GetList()->slice(offset)`

Return type: `list<{type}>`

`sort({list} [, {how} [, {dict}])`

`sort()` E702

Sort the items in `{list}` in-place. Returns `{list}`.

If you want a list to remain unmodified make a copy first:

```
:let sortedlist = sort(copy(mylist))
```

When `{how}` is omitted or is a string, then `sort()` uses the string representation of each item to sort on. Numbers sort after Strings, `Lists` after Numbers. For sorting text in the current buffer use `:sort` .

When `{how}` is given and it is 'i' then case is ignored.

In legacy script, for backwards compatibility, the value one can be used to ignore case. Zero means to not ignore case.

When `{how}` is given and it is `'l'` then the current collation locale is used for ordering. Implementation details: `strcoll()` is used to compare strings. See `:language` check or set the collation locale. `v:collate` can also be used to check the current locale. Sorting using the locale typically ignores case. Example:

```
" ö is sorted similarly to o with English locale.
:language collate en_US.UTF8
:echo sort(['n', 'o', '0', 'ö', 'p', 'z'], 'l')
['n', 'o', '0', 'ö', 'p', 'z']
```

```
" ö is sorted after z with Swedish locale.
:language collate sv_SE.UTF8
:echo sort(['n', 'o', '0', 'ö', 'p', 'z'], 'l')
['n', 'o', '0', 'p', 'z', 'ö']
```

This does not work properly on Mac.

When `{how}` is given and it is `'n'` then all items will be sorted numerical (Implementation detail: this uses the `strtod()` function to parse numbers. Strings, Lists, Dicts and Funcrefs will be considered as being 0). **Note** that this won't sort a list of strings with numbers!

When `{how}` is given and it is `'N'` then all items will be sorted numerical. This is like `'n'` but a string containing digits will be used as the number they represent.

When `{how}` is given and it is `'f'` then all items will be sorted numerical. All values must be a Number or a Float.

When `{how}` is a `Funcref` or a function name, this function is called to compare items. The function is invoked with two items as argument and must return zero if they are equal, 1 or bigger if the first one sorts after the second one, -1 or smaller if the first one sorts before the second one.

`{dict}` is for functions with the "dict" attribute. It will be used to set the local variable "self". [Dictionary-function](#)

The sort is stable, items which compare equal (as number or as string) will keep their relative position. E.g., when sorting on numbers, text strings will sort next to each other, in the same order as they were originally.

Can also be used as a `method` :

```
mylist->sort()
```

Also see `uniq()` .

Example:

```
func MyCompare(i1, i2)
```

```

 return a:i1 == a:i2 ? 0 : a:i1 > a:i2 ? 1 : -1
 endfunc
 eval mylist->sort("MyCompare")

```

A shorter compare version for this specific simple case, which ignores overflow:

```

 func MyCompare(i1, i2)
 return a:i1 - a:i2
 endfunc

```

For a simple expression you can use a lambda:

```

 eval mylist->sort({i1, i2 -> i1 - i2})

```

Return type: list<{type}>

sound\_clear()

sound\_clear()

Stop playing all sounds.

On some Linux systems you may need the libcanberra-pulse package, otherwise sound may not stop.

Return type: Number

{only available when compiled with the |+sound| feature}

sound\_playevent({name} [, {callback}])

sound\_playevent()

Play a sound identified by {name}. Which event names are supported depends on the system. Often the XDG sound names are used. On Ubuntu they may be found in /usr/share/sounds/freedesktop/stereo. Example:

```

 call sound_playevent('bell')

```

On MS-Windows, {name} can be SystemAsterisk, SystemDefault, SystemExclamation, SystemExit, SystemHand, SystemQuestion, SystemStart, SystemWelcome, etc.

On macOS, {name} refers to files located in /System/Library/Sounds (e.g. "Tink"). It will also work for custom installed sounds in folders like ~/Library/Sounds.

When {callback} is specified it is invoked when the sound is finished. The first argument is the sound ID, the second argument is the status:

```

 0 sound was played to the end
 1 sound was interrupted
 2 error occurred after sound started

```

Example:

```

 func Callback(id, status)
 echomsg "sound " .. a:id .. " finished with " .. a:status
 endfunc
 call sound_playevent('bell', 'Callback')

```

MS-Windows: {callback} doesn't work for this function.

Returns the sound ID, which can be passed to `sound\_stop()`. Returns zero if the sound could not be played.

Can also be used as a `method` :  
`GetSoundName()->sound_playevent()`

Return type: `Number`

{only available when compiled with the `|+sound|` feature}

`sound_playfile({path} [, {callback}])` `sound_playfile()`  
Like `'sound_playevent()'` but play sound file `{path}`. `{path}` must be a full path. On Ubuntu you may find files to play with this command:  
`:!find /usr/share/sounds -type f | grep -v index.theme`

Can also be used as a `method` :  
`GetSoundPath()->sound_playfile()`

Return type: `Number`

{only available when compiled with the `|+sound|` feature}

`sound_stop({id})` `sound_stop()`  
Stop playing sound `{id}`. `{id}` must be previously returned by `'sound_playevent()'` or `'sound_playfile()'`.  
On some Linux systems you may need the `libcanberra-pulse` package, otherwise sound may not stop.  
On MS-Windows, this does not work for event sound started by `'sound_playevent()'`. To stop event sounds, use `'sound_clear()'`.

Can also be used as a `method` :  
`soundid->sound_stop()`

Return type: `Number`

{only available when compiled with the `|+sound|` feature}

`soundfold({word})` `soundfold()`  
Return the sound-folded equivalent of `{word}`. Uses the first language in `'spellang'` for the current window that supports soundfolding. `'spell'` must be set. When no sound folding is possible the `{word}` is returned unmodified.  
This can be used for making spelling suggestions. **Note** that the method can be quite slow.

Can also be used as a `method` :  
`GetWord()->soundfold()`

Return type: `String`

spellbadword([`{sentence}`])

spellbadword()

Without argument: The result is the badly spelled word under or after the cursor. The cursor is moved to the start of the bad word. When no bad word is found in the cursor line the result is an empty string and the cursor doesn't move.

With argument: The result is the first word in `{sentence}` that is badly spelled. If there are no spelling mistakes the result is an empty string.

The return value is a list with two items:

- The badly spelled word or an empty string.
- The type of the spelling error:

"bad"	spelling mistake
"rare"	rare word
"local"	word only valid in another region
"caps"	word should start with Capital

Example:

```
echo spellbadword("the quik brown fox")
['quik', 'bad']
```

The spelling information for the current window and the value of '`spelllang`' are used.

Can also be used as a `method` :

```
GetText()->spellbadword()
```

Return type: `list<string>`

spellsuggest(`{word}` [, `{max}` [, `{capital}`]])

spellsuggest()

Return a `List` with spelling suggestions to replace `{word}`. When `{max}` is given up to this number of suggestions are returned. Otherwise up to 25 suggestions are returned.

When the `{capital}` argument is given and it's non-zero only suggestions with a leading capital will be given. Use this after a match with '`spellcapcheck`'.

`{word}` can be a badly spelled word followed by other text. This allows for joining two words that were split. The suggestions also include the following text, thus you can replace a line.

`{word}` may also be a good word. Similar words will then be returned. `{word}` itself is not included in the suggestions, although it may appear capitalized.

The spelling information for the current window is used. The values of '`spelllang`' and '`spellsuggest`' are used.

Can also be used as a `method` :

```
GetWord()->spellsuggest()
```

Return type: list<string> or list<any>

`split({string} [, {pattern} [, {keepempty}]])` `split()`  
Make a `List` out of `{string}`. When `{pattern}` is omitted or empty each white space separated sequence of characters becomes an item.  
Otherwise the string is split where `{pattern}` matches, removing the matched characters. `'ignorecase'` is not used here, add `\c` to ignore case. `/\c`  
When the first or last item is empty it is omitted, unless the `{keepempty}` argument is given and it's non-zero.  
Other empty items are kept when `{pattern}` matches at least one character or when `{keepempty}` is non-zero.  
Example:

```
:let words = split(getline('.'), '\W+')
```

To split a string in individual characters:

```
:for c in split(mystring, '\zs')
```

If you want to keep the separator you can also use `'\zs'` at the end of the pattern:

```
:echo split('abc:def:ghi', ':\zs')
['abc:', 'def:', 'ghi']
```

Splitting a table where the first element can be empty:

```
:let items = split(line, ':', 1)
```

The opposite function is `join()` .

Can also be used as a `method` :

```
GetString()->split()
```

Return type: list<string>

`sqrt({expr})` `sqrt()`  
Return the non-negative square root of `Float {expr}` as a `Float` .  
`{expr}` must evaluate to a `Float` or a `Number` . When `{expr}` is negative the result is NaN (Not a Number). Returns 0.0 if `{expr}` is not a `Float` or a `Number` .

Examples:

```
:echo sqrt(100)
10.0
:echo sqrt(-4.01)
nan
```

"nan" may be different, it depends on system libraries.

Can also be used as a `method` :

```
Compute()->sqrt()
```

Return type: `Float`

`srand([{expr}])` `srand()`  
Initialize seed used by `rand()` :  
- If `{expr}` is not given, seed values are initialized by

- reading from /dev/urandom, if possible, or using time(NULL) a.k.a. epoch time otherwise; this only has second accuracy.
- If {expr} is given it must be a Number. It is used to initialize the seed values. This is useful for testing or when a predictable sequence is intended.

Examples:

```
:let seed = srand()
:let seed = srand(userinput)
:echo rand(seed)
```

Return type: list<number>

state([{what}])

state()

Return a string which contains characters indicating the current state. Mostly useful in callbacks that want to do work that may not always be safe. Roughly this works like:

- callback uses state() to check if work is safe to do.

Yes: then do it right away.

No: add to work queue and add a `SafeState` and/or `SafeStateAgain` autocommand (`SafeState` triggers at toplevel, `SafeStateAgain` triggers after handling messages and callbacks).

- When `SafeState` or `SafeStateAgain` is triggered and executes your autocommand, check with `state()` if the work can be done now, and if yes remove it from the queue and execute. Remove the autocommand if the queue is now empty.

Also see `mode()` .

When {what} is given only characters in this string will be added. E.g, this checks if the screen has scrolled:

```
if state('s') == ''
 " screen has not scrolled
```

These characters indicate the state, generally indicating that something is busy:

- m halfway a mapping, :normal command, feedkeys() or stuffed command
- o operator pending, e.g. after `d`
- a Insert mode autocomplete active
- x executing an autocommand
- w blocked on waiting, e.g. `ch_evalexpr()`, `ch_read()` and `ch_readraw()` when reading json
- S not triggering `SafeState` or `SafeStateAgain`, e.g. after `f` or a count
- c callback invoked, including timer (repeats for recursiveness up to "ccc")
- s screen has scrolled for messages

Return type: `String`

str2blob({list} [, {options}])

str2blob()

Return a Blob by converting the characters in the List of strings in `{list}` into bytes.

A `<NL>` byte is added to the blob after each list item. A newline character in the string is translated into a `<NUL>` byte in the blob.

If `{options}` is not supplied, the current `'encoding'` value is used to convert the characters into bytes.

The argument `{options}` is a `Dict` and supports the following items:

`encoding` Convert the characters using this encoding before making the Blob. The value is a `String`. See [encoding-names](#) for the supported values.

An error is given and an empty blob is returned if the character encoding fails.

Returns an empty Blob if `{list}` is empty.

See also [blob2str\(\)](#)

Examples:

```
str2blob(["ab"]) returns 0z6162
str2blob(["«»"]) returns 0zC2ABC2BB
str2blob(["a\nb"]) returns 0z610A62
str2blob(readfile('myfile.txt'))
str2blob(["«»"], {'encoding': 'latin1'}) returns 0zABBB
```

Can also be used as a `method` :

```
GetListOfStrings()->str2blob()
```

Return type: `Blob`

`str2float({string} [, {quoted}])` `str2float()`

Convert String `{string}` to a Float. This mostly works the same as when using a floating point number in an expression, see [floating-point-format](#). But it's a bit more permissive. E.g., "1e40" is accepted, while in an expression you need to write "1.0e40". The hexadecimal form "0x123" is also accepted, but not others, like binary or octal.

When `{quoted}` is present and non-zero then embedded single quotes before the dot are ignored, thus "1'000.0" is a thousand.

Text after the number is silently ignored.

The decimal point is always '.', no matter what the locale is set to. A comma ends the number: "12,345.67" is converted to 12.0. You can strip out thousands separators with

```
substitute() :
 let f = str2float(substitute(text, ',', '', 'g'))
```

Returns 0.0 if the conversion fails.

Can also be used as a `method` :

```
let f = text->substitute(',', ' ', 'g')->str2float()
```

Return type: `Float`

`str2list({string} [, {utf8}])` `str2list()`

Return a list containing the number values which represent each character in String `{string}`. Examples:

```
str2list(" ") returns [32]
str2list("ABC") returns [65, 66, 67]
```

`list2str()` does the opposite.

When `{utf8}` is omitted or zero, the current `'encoding'` is used.

When `{utf8}` is TRUE, always treat the String as UTF-8 characters. With UTF-8 composing characters are handled properly:

```
str2list("á") returns [97, 769]
```

Can also be used as a `method` :

```
GetString()->str2list()
```

Return type: `list<number>`

`str2nr({string} [, {base} [, {quoted}])` `str2nr()`

Convert string `{string}` to a number.

`{base}` is the conversion base, it can be 2, 8, 10 or 16.

When `{quoted}` is present and non-zero then embedded single quotes are ignored, thus `"1'000'000"` is a million.

When `{base}` is omitted base 10 is used. This also means that a leading zero doesn't cause octal conversion to be used, as with the default String to Number conversion. Example:

```
let nr = str2nr('0123')
```

When `{base}` is 16 a leading `"0x"` or `"0X"` is ignored. With a different base the result will be zero. Similarly, when `{base}` is 8 a leading `"0"`, `"0o"` or `"0O"` is ignored, and when `{base}` is 2 a leading `"0b"` or `"0B"` is ignored.

Text after the number is silently ignored.

Returns 0 if `{string}` is empty or on error.

Can also be used as a `method` :

```
GetText()->str2nr()
```

Return type: `Number`

`strcharlen({string})` `strcharlen()`

The result is a Number, which is the number of characters in String `{string}`. Composing characters are ignored.

`strchars()` can count the number of characters, counting composing characters separately.

Returns 0 if `{string}` is empty or on error.

Also see `strlen()` , `strdisplaywidth()` and `strwidth()` .

Can also be used as a `method` :  
`GetText()->strcharlen()`

Return type: `Number`

`strcharpart({src}, {start} [, {len} [, {skipcc}]])` `strcharpart()`

Like `strpart()` but using character index and length instead of byte index and length.

When `{skipcc}` is omitted or zero, composing characters are counted separately.

When `{skipcc}` set to 1, composing characters are treated as a part of the preceding base character, similar to `slice()` .

When a character index is used where a character does not exist it is omitted and counted as one character. For example:

```
strcharpart('abc', -1, 2)
results in 'a'.
```

Returns an empty string on error.

Can also be used as a `method` :  
`GetText()->strcharpart(5)`

Return type: `String`

`strchars({string} [, {skipcc}])` `strchars()`

The result is a `Number`, which is the number of characters in `String {string}`.

When `{skipcc}` is omitted or zero, composing characters are counted separately.

When `{skipcc}` set to 1, composing characters are ignored. `strcharlen()` always does this.

Returns zero on error.

Also see `strlen()` , `strdisplaywidth()` and `strwidth()` .

`{skipcc}` is only available after 7.4.755. For backward compatibility, you can define a wrapper function:

```
if has("patch-7.4.755")
 function s:strchars(str, skipcc)
 return strchars(a:str, a:skipcc)
 endfunction
else
 function s:strchars(str, skipcc)
```

```

 if a:skipcc
 return strlen(substitute(a:str, ".", "x", "g"))
 else
 return strchars(a:str)
 endif
 endfunction
endif

```

Can also be used as a `method` :  
`GetText()->strchars()`

Return type: `Number`

`strdisplaywidth({string} [, {col}])` `strdisplaywidth()`

The result is a `Number`, which is the number of display cells String `{string}` occupies on the screen when it starts at `{col}` (first column is zero). When `{col}` is omitted zero is used. Otherwise it is the screen column where to start. This matters for Tab characters.

The option settings of the current window are used. This matters for anything that's displayed differently, such as `'tabstop'` and `'display'`.

When `{string}` contains characters with East Asian Width Class Ambiguous, this function's return value depends on `'ambiwidth'`. Returns zero on error.

Also see `strlen()` , `strwidth()` and `strchars()` .

Can also be used as a `method` :  
`GetText()->strdisplaywidth()`

Return type: `Number`

`strftime({format} [, {time}])` `strftime()`

The result is a `String`, which is a formatted date and time, as specified by the `{format}` string. The given `{time}` is used, or the current time if no time is given. The accepted `{format}` depends on your system, thus this is not portable! See the manual page of the C function `strftime()` for the format. The maximum length of the result is 80 characters. See also `localtime()` , `getftime()` and `strptime()` .

The language can be changed with the `:language` command.

Examples:

```

:echo strftime("%c") Sun Apr 27 11:49:23 1997
:echo strftime("%Y %b %d %X") 1997 Apr 27 11:53:25
:echo strftime("%y%m%d %T") 970427 11:53:55
:echo strftime("%H:%M") 11:55
:echo strftime("%c", getftime("file.c"))
 Show mod time of file.c.

```

Not available on all systems. To check use:  
`:if exists("*strftime")`

Can also be used as a `method` :

GetFormat()->strftime()

Return type: String

strgetchar({str}, {index})

strgetchar()

Get a Number corresponding to the character at {index} in {str}. This uses a zero-based character index, not a byte index. Composing characters are considered separate characters here. Use nr2char() to convert the Number to a String.

Returns -1 if {index} is invalid.

Also see strchrpart() and strchr().

Can also be used as a method :

GetText()->strgetchar(5)

Return type: Number

stridx({haystack}, {needle} [, {start}])

stridx()

The result is a Number, which gives the byte index in {haystack} of the first occurrence of the String {needle}.

If {start} is specified, the search starts at index {start}.

This can be used to find a second match:

```
:let colon1 = stridx(line, ":")
```

```
:let colon2 = stridx(line, ":", colon1 + 1)
```

The search is done case-sensitive.

For pattern searches use match() .

-1 is returned if the {needle} does not occur in {haystack}.

See also stridx() .

Examples:

```
:echo stridx("An Example", "Example") 3
```

```
:echo stridx("Starting point", "Start") 0
```

```
:echo stridx("Starting point", "start") -1
```

strstr() strchr()

stridx() works similar to the C function strstr(). When used with a single character it works similar to strchr().

Can also be used as a method :

GetHaystack()->stridx(needle)

Return type: Number

string({expr})

string()

Return {expr} converted to a String. If {expr} is a Number, Float, String, Blob or a composition of them, then the result can be parsed back with eval() .

{expr} type	result
-------------	--------

String	'string' (single quotes are doubled)
--------	--------------------------------------

Number	123
--------	-----

Float	123.123456 or 1.123456e8
-------	--------------------------

Funcref	function('name')
---------	------------------

Blob	0z00112233.44556677.8899
List	[item, item]
Dictionary	{key: value, key: value}
Class	class SomeName
Object	object of SomeName {lnum: 1, col: 3}
Enum	enum EnumName
EnumValue	enum name.value {name: str, ordinal: nr}

When a `List` or `Dictionary` has a recursive reference it is replaced by "[...]" or "{...}". Using `eval()` on the result will then fail.

For an object, invokes the `string()` method to get a textual representation of the object. If the method is not present, then the default representation is used. `object-string()`

Can also be used as a `method` :  
`mylist->string()`

Also see `strtrans()` .

Return type: `String`

`strlen({string})` `strlen()`

The result is a `Number`, which is the length of the `String` `{string}` in bytes.

If the argument is a `Number` it is first converted to a `String`. For other types an error is given and zero is returned.

If you want to count the number of multibyte characters use `strchars()` .

Also see `len()` , `strdisplaywidth()` and `strwidth()` .

Can also be used as a `method` :  
`GetString()->strlen()`

Return type: `Number`

`strpart({src}, {start} [, {len} [, {chars}]])` `strpart()`

The result is a `String`, which is part of `{src}`, starting from byte `{start}`, with the byte length `{len}`.

When `{chars}` is present and `TRUE` then `{len}` is the number of characters positions (composing characters are not counted separately, thus "1" means one base character and any following composing characters).

To count `{start}` as characters instead of bytes use `strcharpart()` .

When bytes are selected which do not exist, this doesn't result in an error, the bytes are simply omitted.

If `{len}` is missing, the copy continues from `{start}` till the end of the `{src}`.

`strpart("abcdefg", 3, 2) == "de"`

```
strpart("abcdefg", -2, 4) == "ab"
strpart("abcdefg", 5, 4) == "fg"
strpart("abcdefg", 3) == "defg"
```

**Note:** To get the first character, `{start}` must be 0. For example, to get the character under the cursor:

```
strpart(getline("."), col(".") - 1, 1, v:true)
```

Returns an empty string on error.

Can also be used as a `method` :

```
GetText()->strpart(5)
```

Return type: `String`

`strptime({format}, {timestring})` `strptime()`

The result is a Number, which is a unix timestamp representing the date and time in `{timestring}`, which is expected to match the format specified in `{format}`.

The accepted `{format}` depends on your system, thus this is not portable! See the manual page of the C function `strptime()` for the format. Especially avoid `"%c"`. The value of `$TZ` also matters.

If the `{timestring}` cannot be parsed with `{format}` zero is returned. If you do not know the format of `{timestring}` you can try different `{format}` values until you get a non-zero result.

See also `strftime()` .

Examples:

```
:echo strptime("%Y %b %d %X", "1997 Apr 27 11:49:23")
862156163
:echo strftime("%c", strptime("%y%m%d %T", "970427 11:53:55"))
Sun Apr 27 11:53:55 1997
:echo strftime("%c", strptime("%Y%m%d%H%M%S", "19970427115355") + 3600)
Sun Apr 27 12:53:55 1997
```

Can also be used as a `method` :

```
GetFormat()->strptime(timestring)
```

Not available on all systems. To check use:

```
:if exists("*strptime")
```

Return type: `Number`

`stridx({haystack}, {needle} [, {start}])` `stridx()`

The result is a Number, which gives the byte index in `{haystack}` of the last occurrence of the String `{needle}`. When `{start}` is specified, matches beyond this index are ignored. This can be used to find a match before a previous

```
match:
 :let lastcomma = stridx(line, ",")
 :let comma2 = stridx(line, ",", lastcomma - 1)
```

The search is done case-sensitive.

For pattern searches use `match()` .

-1 is returned if the `{needle}` does not occur in `{haystack}`.

If the `{needle}` is empty the length of `{haystack}` is returned.

See also `stridx()` . Examples:

```
:echo stridx("an angry armadillo", "an") 3
 strchr()
```

When used with a single character it works similar to the C function `strchr()`.

Can also be used as a `method` :

```
GetHaystack()->stridx(needle)
```

Return type: `Number`

```
strtrans({string}) strtrans()
```

The result is a String, which is `{string}` with all unprintable characters translated into printable characters `'isprint'` .

Like they are shown in a window. Example:

```
echo strtrans(@a)
```

This displays a newline in register a as `"^@"` instead of starting a new line.

Returns an empty string on error.

Can also be used as a `method` :

```
GetString()->strtrans()
```

Return type: `String`

```
strutf16len({string} [, {countcc}]) strutf16len()
```

The result is a Number, which is the number of UTF-16 code units in String `{string}` (after converting it to UTF-16).

When `{countcc}` is TRUE, composing characters are counted separately.

When `{countcc}` is omitted or FALSE, composing characters are ignored.

Returns zero on error.

Also see `strlen()` and `strcharlen()` .

Examples:

```
echo strutf16len('a') returns 1
echo strutf16len('@') returns 1
echo strutf16len('␣') returns 2
echo strutf16len('á') returns 1
echo strutf16len('á', v:true) returns 3
```

Can also be used as a `method` :  
`GetText()->strutf16len()`

Return type: `Number`

`strwidth({string})` `strwidth()`

The result is a `Number`, which is the number of display cells `String {string}` occupies. A Tab character is counted as one cell, alternatively use `strdisplaywidth()` .

When `{string}` contains characters with East Asian Width Class Ambiguous, this function's return value depends on `'ambiwidht'`. Returns zero on error.

Also see `strlen()` , `strdisplaywidth()` and `strchars()` .

Can also be used as a `method` :  
`GetString()->strwidth()`

Return type: `Number`

`submatch({nr} [, {list}])` `submatch()` E935

Only for an expression in a `:substitute` command or `substitute()` function.

Returns the `{nr}`'th submatch of the matched text. When `{nr}` is 0 the whole matched text is returned.

**Note** that a NL in the string can stand for a line break of a multi-line match or a NUL character in the text.

Also see `sub-replace-expression` .

If `{list}` is present and non-zero then `submatch()` returns a list of strings, similar to `getline()` with two arguments. NL characters in the text represent NUL characters in the text.

Only returns more than one item for `:substitute` , inside `substitute()` this list will always contain one or zero items, since there are no real line breaks.

When `substitute()` is used recursively only the submatches in the current (deepest) call can be obtained.

Returns an empty string or list on error.

Examples:

```
:s/\d\+/\=submatch(0) + 1/
```

```
:echo substitute(text, '\d\+', '\=submatch(0) + 1', '')
```

This finds the first number in the line and adds one to it.

A line break is included as a newline character.

Can also be used as a `method` :  
`GetNr()->submatch()`

Return type: `String` or `list<string>` depending on `{list}`

`substitute({string}, {pat}, {sub}, {flags})` `substitute()`

The result is a String, which is a copy of `{string}`, in which the first match of `{pat}` is replaced with `{sub}`.

When `{flags}` is "g", all matches of `{pat}` in `{string}` are replaced. Otherwise `{flags}` should be "".

This works like the `":substitute"` command (without any flags). But the matching with `{pat}` is always done like the `'magic'` option is set and `'coptions'` is empty (to make scripts portable). `'ignorecase'` is still relevant, use `/\c` or `/\C` if you want to ignore or match case and ignore `'ignorecase'`. `'smartcase'` is not used. See `string-match` for how `{pat}` is used.

A `"~"` in `{sub}` is not replaced with the previous `{sub}`.

**Note** that some codes in `{sub}` have a special meaning `sub-replace-special`. For example, to replace something with `"\n"` (two characters), use `"\\n"` or `'\n'`.

When `{pat}` does not match in `{string}`, `{string}` is returned unmodified.

Example:

```
:let &path = substitute(&path, "\\=[^,]*$", "", "")
```

This removes the last component of the `'path'` option.

```
:echo substitute("testing", ".*", "\\U\\@", "")
```

results in "TESTING".

When `{sub}` starts with `"\"`, the remainder is interpreted as an expression. See `sub-replace-expression`. Example:

```
:echo substitute(s, '%\\(\\x\\x\\)',
 \\ '\\=nr2char("0x" .. submatch(1))', 'g')
```

When `{sub}` is a Funcref that function is called, with one optional argument. Example:

```
:echo substitute(s, '%\\(\\x\\x\\)', SubNr, 'g')
```

The optional argument is a list which contains the whole matched string and up to nine submatches, like what `submatch()` returns. Example:

```
:echo substitute(s, '%\\(\\x\\x\\)', {m -> '0x' .. m[1]}, 'g')
```

Returns an empty string on error.

Can also be used as a `method` :

```
GetString()->substitute(pat, sub, flags)
```

Return type: `String`

`swapfilelist()` `swapfilelist()`

Returns a list of swap file names, like what `"vim -r"` shows. See the `-r` command argument. The `'directory'` option is used for the directories to inspect. If you only want to get a

list of swap files in the current directory then temporarily set **'directory'** to a dot:

```
let save_dir = &directory
let &directory = '.'
let swapfiles = swapfilelist()
let &directory = save_dir
```

Return type: list<string>

swapinfo({fname})

swapinfo()

The result is a dictionary, which holds information about the swapfile {fname}. The available fields are:

```
version Vim version
user user name
host host name
fname original file name
pid PID of the Vim process that created the swap
 file
mtime last modification time in seconds
inode Optional: INODE number of the file
dirty 1 if file was modified, 0 if not
```

**Note** that "user" and "host" are truncated to at most 39 bytes.

In case of failure an "error" item is added with the reason:

```
Cannot open file: file not found or in accessible
Cannot read file: cannot read first block
Not a swap file: does not contain correct block ID
Magic number mismatch: Info in first block is invalid
```

Can also be used as a **method** :

```
GetFilename()->swapinfo()
```

Return type: dict<any> or dict<string>

swapname({buf})

swapname()

The result is the swap file path of the buffer {buf}.

For the use of {buf}, see **bufname()** above.

If buffer {buf} is the current buffer, the result is equal to **:swapname** (unless there is no swap file).

If buffer {buf} has no swap file, returns an empty string.

Can also be used as a **method** :

```
GetBufname()->swapname()
```

Return type: **String**

synID({lnum}, {col}, {trans})

synID()

The result is a Number, which is the syntax ID at the position {lnum} and {col} in the current window.

The syntax ID can be used with **synIDattr()** and **synIDtrans()** to obtain syntax information about text.

`{col}` is 1 for the leftmost column, `{lnum}` is 1 for the first line. `'synmaxcol'` applies, in a longer line zero is returned. **Note** that when the position is after the last character, that's where the cursor can be in Insert mode, `synID()` returns zero. `{lnum}` is used like with `getline()` .

When `{trans}` is `TRUE` , transparent items are reduced to the item that they reveal. This is useful when wanting to know the effective color. When `{trans}` is `FALSE` , the transparent item is returned. This is useful when wanting to know which syntax item is effective (e.g. inside parens).

Warning: This function can be very slow. Best speed is obtained by going through the file in forward direction.

Returns zero on error.

Example (echoes the name of the syntax item under the cursor):  
`:echo synIDattr(synID(line("."), col("."), 1), "name")`

Return type: `Number`

`synIDattr({synID}, {what} [, {mode}])`

`synIDattr()`

The result is a String, which is the `{what}` attribute of syntax ID `{synID}`. This can be used to obtain information about a syntax item.

`{mode}` can be "gui", "cterm" or "term", to get the attributes for that mode. When `{mode}` is omitted, or an invalid value is used, the attributes for the currently active highlighting are used (GUI, cterm or term).

Use `synIDtrans()` to follow linked highlight groups.

<code>{what}</code>	result
"name"	the name of the syntax item
"fg"	foreground color (GUI: color name used to set the color, cterm: color number as a string, term: empty string)
"bg"	background color (as with "fg")
"font"	font name (only available in the GUI) <code>highlight-font</code>
"sp"	special color for the GUI (as with "fg") <code>highlight-guisp</code>
"ul"	underline color for cterm: number as a string
"fg#"	like "fg", but for the GUI and the GUI is running the name in "#RRGGBB" form
"bg#"	like "fg#" for "bg"
"sp#"	like "fg#" for "sp"
"bold"	"1" if bold
"italic"	"1" if italic
"reverse"	"1" if reverse
"inverse"	"1" if inverse (= reverse)
"standout"	"1" if standout
"underline"	"1" if underlined
"undercurl"	"1" if undercurled
"strike"	"1" if strikethrough

```
"nocombine" "1" if nocombine
```

Returns an empty string on error.

Example (echoes the color of the syntax item under the cursor):

```
:echo synIDattr(synIDtrans(synID(line("."), col("."), 1)), "fg")
```

Can also be used as a `method` :

```
:echo synID(line("."), col("."), 1)->synIDtrans()->synIDattr("fg")
```

Return type: `String`

`synIDtrans({synID})`

`synIDtrans()`

The result is a Number, which is the translated syntax ID of `{synID}`. This is the syntax group ID of what is being used to highlight the character. Highlight links given with `":highlight link"` are followed.

Returns zero on error.

Can also be used as a `method` :

```
:echo synID(line("."), col("."), 1)->synIDtrans()->synIDattr("fg")
```

Return type: `Number`

`synconcealed({lnum}, {col})`

`synconcealed()`

The result is a `List` with currently three items:

1. The first item in the list is 0 if the character at the position `{lnum}` and `{col}` is not part of a concealable region, 1 if it is. `{lnum}` is used like with `getline()`.
2. The second item in the list is a string. If the first item is 1, the second item contains the text which will be displayed in place of the concealed text, depending on the current setting of `'conceallevel'` and `'listchars'`.
3. The third and final item in the list is a number representing the specific syntax region matched in the line. When the character is not concealed the value is zero. This allows detection of the beginning of a new concealable region if there are two consecutive regions with the same replacement character. For an example, if the text is "123456" and both "23" and "45" are concealed and replaced by the character "X", then:

<code>call</code>	<code>returns</code>
<code>synconcealed(lnum, 1)</code>	<code>[0, '', 0]</code>
<code>synconcealed(lnum, 2)</code>	<code>[1, 'X', 1]</code>
<code>synconcealed(lnum, 3)</code>	<code>[1, 'X', 1]</code>
<code>synconcealed(lnum, 4)</code>	<code>[1, 'X', 2]</code>
<code>synconcealed(lnum, 5)</code>	<code>[1, 'X', 2]</code>
<code>synconcealed(lnum, 6)</code>	<code>[0, '', 0]</code>

**Note:** Doesn't consider `matchadd()` highlighting items,

since syntax and matching highlighting are two different mechanisms [syntax-vs-match](#) .

Return type: list<any>

synstack({lnum}, {col})

synstack()

Return a [List](#) , which is the stack of syntax items at the position {lnum} and {col} in the current window. {lnum} is used like with [getline\(\)](#) . Each item in the List is an ID like what [synID\(\)](#) returns.

The first item in the List is the outer region, following are items contained in that one. The last one is what [synID\(\)](#) returns, unless not the whole item is highlighted or it is a transparent item.

This function is useful for debugging a syntax file.

Example that shows the syntax stack under the cursor:

```
for id in synstack(line("."), col("."))
 echo synIDattr(id, "name")
endfor
```

When the position specified with {lnum} and {col} is invalid an empty List is returned. The position just after the last character in a line and the first column in an empty line are valid positions.

Return type: list<number> or list<any>

system({expr} [, {input}])

system() E677

Get the output of the shell command {expr} as a [String](#) . See [systemlist\(\)](#) to get the output as a [List](#) .

When {input} is given and is a [String](#) this string is written to a file and passed as stdin to the command. The string is written as-is, you need to take care of using the correct line separators yourself.

If {input} is given and is a [List](#) it is written to the file in a way [writefile\(\)](#) does with {binary} set to "b" (i.e. with a newline between each list item with newlines inside list items converted to NULs).

When {input} is given and is a number that is a valid id for an existing buffer then the content of the buffer is written to the file line by line, each line terminated by a NL and NULs characters where the text has a NL.

Pipes are not used, the **'shelltemp'** option is not used.

When prepended by [:silent](#) the terminal will not be set to cooked mode. This is meant to be used for commands that do not need the user to type. It avoids stray characters showing up on the screen which require [CTRL-L](#) to remove.

```
:silent let f = system('ls *.vim')
```

**Note:** Use [shellescape\(\)](#) or [::S](#) with [expand\(\)](#) or

`fnamemodify()` to escape special characters in a command argument. Newlines in `{expr}` may cause the command to fail. The characters in `'shellquote'` and `'shellxquote'` may also cause trouble. This is not to be used for interactive commands.

The result is a String. Example:

```
:let files = system('ls ' .. shellescape(expand('%:h')))
:let files = system('ls ' .. expand('%:h:S'))
```

To make the result more system-independent, the shell output is filtered to replace `<CR>` with `<NL>` for Macintosh, and `<CR><NL>` with `<NL>` for DOS-like systems. To avoid the string being truncated at a NUL, all NUL characters are replaced with SOH (0x01).

The command executed is constructed using several options:

```
'shell' 'shellcmdflag' 'shellxquote' {expr} 'shellredir' {tmp} 'shellxquote'
({tmp} is an automatically generated file name).
For Unix, braces are put around {expr} to allow for
concatenated commands.
```

The command will be executed in "cooked" mode, so that a **CTRL-C** will interrupt the command (on Unix at least).

The resulting error code can be found in `v:shell_error`. This function will fail in `restricted-mode`.

**Note** that any wrong value in the options mentioned above may make the function fail. It has also been reported to fail when using a security agent application. Unlike `:!cmd` there is no automatic check for changed files. Use `:checktime` to force a check.

Can also be used as a `method` :

```
:echo GetCmd()->system()
```

Return type: `String`

`systemlist({expr} [, {input}])` `systemlist()`  
Same as `system()`, but returns a `List` with lines (parts of output separated by NL) with NULs transformed into NLs. Output is the same as `readfile()` will output with `{binary}` argument set to "b", except that there is no extra empty item when the result ends in a NL.

**Note** that on MS-Windows you may get trailing CR characters.

To see the difference between "echo hello" and "echo -n hello" use `system()` and `split()` :

```
echo system('echo hello')->split('\n', 1)
```

Returns an empty string on error.

Can also be used as a `method` :  
`:echo GetCmd()->systemlist()`

Return type: `list<string>`

`tabpagebuflist([{arg}])` `tabpagebuflist()`  
The result is a `List`, where each item is the number of the buffer associated with each window in the current tab page. `{arg}` specifies the number of the tab page to be used. When omitted the current tab page is used.

When `{arg}` is invalid the number zero is returned.

To get a list of all buffers in all tabs use this:

```
let buflist = []
for i in range(tabpagenr('$'))
 call extend(buflist, tabpagebuflist(i + 1))
endfor
```

**Note** that a buffer may appear in more than one window.

Can also be used as a `method` :  
`GetTabPage()->tabpagebuflist()`

Return type: `list<number>`

`tabpagenr([{arg}])` `tabpagenr()`  
The result is a `Number`, which is the number of the current tab page. The first tab page has number 1.

The optional argument `{arg}` supports the following values:

- `$` the number of the last tab page (the tab page count).
- `#` the number of the last accessed tab page (where `g<Tab>` goes to). if there is no previous tab page 0 is returned.

The number can be used with the `:tab` command.

Returns zero on error.

Return type: `Number`

`tabpagewinnr({tabarg} [, {arg}])` `tabpagewinnr()`  
Like `winnr()` but for tab page `{tabarg}`.

`{tabarg}` specifies the number of tab page to be used.

`{arg}` is used like with `winnr()` :

- When omitted the current window number is returned. This is the window which will be used when going to this tab page.
- When `"$"` the number of windows is returned.
- When `"#"` the previous window nr is returned.

Useful examples:

```
tabpagewinnr(1) " current window of tab page 1
tabpagewinnr(4, '$') " number of windows in tab page 4
```

When `{tabarg}` is invalid zero is returned.

Can also be used as a [method](#) :  
`GetTabPage()->tabpagewinnr()`

Return type: [Number](#)

`tagfiles()`

[tagfiles\(\)](#)

Returns a [List](#) with the file names used to search for tags for the current buffer. This is the `'tags'` option expanded.

Return type: `list<string>` or `list<any>`

`taglist({expr} [, {filename}])`

[taglist\(\)](#)

Returns a [List](#) of tags matching the regular expression `{expr}`.

If `{filename}` is passed it is used to prioritize the results in the same way that `:tselect` does. See [tag-priority](#). `{filename}` should be the full path of the file.

Each list item is a dictionary with at least the following entries:

<code>name</code>	Name of the tag.
<code>filename</code>	Name of the file where the tag is defined. It is either relative to the current directory or a full path.
<code>cmd</code>	Ex command used to locate the tag in the file.
<code>kind</code>	Type of the tag. The value for this entry depends on the language specific kind values. Only available when using a tags file generated by Universal/Exuberant ctags or hdrtag.
<code>static</code>	A file specific tag. Refer to <a href="#">static-tag</a> for more information.

More entries may be present, depending on the content of the tags file: `access`, `implementation`, `inherits` and `signature`. Refer to the ctags documentation for information about these fields. For C code the fields `"struct"`, `"class"` and `"enum"` may appear, they give the name of the entity the tag is contained in.

The ex-command `"cmd"` can be either an ex search pattern, a line number or a line number followed by a byte number.

If there are no matching tags, then an empty list is returned.

To get an exact tag match, the anchors `'^'` and `'$'` should be used in `{expr}`. This also make the function work faster. Refer to [tag-regexp](#) for more information about the tag search regular expression pattern.

Refer to `'tags'` for information about how the tags file is

located by Vim. Refer to `tags-file-format` for the format of the tags file generated by the different ctags tools.

Can also be used as a `method` :  
`GetTagpattern()->taglist()`

Return type: `list<dict<any>>` or `list<any>`

`tan({expr})`

`tan()`

Return the tangent of `{expr}`, measured in radians, as a `Float` in the range `[-inf, inf]`.

`{expr}` must evaluate to a `Float` or a `Number` .

Returns `0.0` if `{expr}` is not a `Float` or a `Number` .

Examples:

```
:echo tan(10)
0.648361
:echo tan(-4.01)
-1.181502
```

Can also be used as a `method` :  
`Compute()->tan()`

Return type: `Float`

`tanh({expr})`

`tanh()`

Return the hyperbolic tangent of `{expr}` as a `Float` in the range `[-1, 1]`.

`{expr}` must evaluate to a `Float` or a `Number` .

Returns `0.0` if `{expr}` is not a `Float` or a `Number` .

Examples:

```
:echo tanh(0.5)
0.462117
:echo tanh(-1)
-0.761594
```

Can also be used as a `method` :  
`Compute()->tanh()`

Return type: `Float`

`tempname()`

`tempname()` `temp-file-name`

The result is a String, which is the name of a file that doesn't exist. It can be used for a temporary file. The name is different for at least 26 consecutive calls. Example:

```
:let tmpfile = tempname()
:exe "redir > " .. tmpfile
```

For Unix, the file will be in a private directory `tmpfile` that is recursively deleted when Vim exits, on other systems temporary files are not cleaned up automatically on exit. For MS-Windows forward slashes are used when the `'shellslash'` option is set, or when `'shellcmdflag'` starts with `'-'` and

'shell' does not contain powershell or pwsh.

Return type: `String`

term\_ functions are documented here: [terminal-function-details](#)

`terminalprops()` `terminalprops()`

Returns a `Dictionary` with properties of the terminal that Vim detected from the response to `t_RV` request. See `v:termresponse` for the response itself. If `v:termresponse` is empty most values here will be 'u' for unknown.

<code>cursor_style</code>	whether sending <code>t_RS</code> works	**
<code>cursor_blink_mode</code>	whether sending <code>t_RC</code> works	**
<code>underline_rgb</code>	whether <code>t_8u</code> works	**
<code>mouse</code>	mouse type supported	
<code>kitty</code>	whether Kitty terminal was detected	

\*\* value 'u' for unknown, 'y' for yes, 'n' for no

If the `+termresponse` feature is missing then the result is an empty dictionary.

If "cursor\_style" is 'y' then `t_RS` will be sent to request the current cursor style.  
If "cursor\_blink\_mode" is 'y' then `t_RC` will be sent to request the cursor blink status.  
"cursor\_style" and "cursor\_blink\_mode" are also set if `t_u7` is not empty, Vim will detect the working of sending `t_RS` and `t_RC` on startup.

When "underline\_rgb" is not 'y', then `t_8u` will be made empty. This avoids sending it to xterm, which would clear the colors.

For "mouse" the value 'u' is unknown

Also see:

- `'ambiwidth'` - detected by using `t_u7` .
- `v:termstylersp` and `v:termblinkresp` for the response to `t_RS` and `t_RC` .

Return type: `dict<string>`

test\_ functions are documented here: [test-functions-details](#)

`timer_info([id])` `timer_info()`

Return a list with information about timers.  
When `{id}` is given only information about this timer is returned. When timer `{id}` does not exist an empty list is returned.

When `{id}` is omitted information about all timers is returned.

For each timer the information is stored in a `Dictionary` with these items:

"id"	the timer ID
"time"	time the timer was started with
"remaining"	time until the timer fires
"repeat"	number of times the timer will still fire; -1 means forever
"callback"	the callback
"paused"	1 if the timer is paused, 0 otherwise

Can also be used as a `method` :  
`GetTimer()->timer_info()`

Return type: `list<dict<any>>` or `list<any>`

`{only available when compiled with the |+timers| feature}`

`timer_pause({timer}, {paused})` `timer_pause()`

Pause or unpaue a timer. A paused timer does not invoke its callback when its time expires. Unpausing a timer may cause the callback to be invoked almost immediately if enough time has passed.

Pausing a timer is useful to avoid the callback to be called for a short time.

If `{paused}` evaluates to a non-zero Number or a non-empty String, then the timer is paused, otherwise it is unpaused. See `non-zero-arg` .

Can also be used as a `method` :  
`GetTimer()->timer_pause(1)`

Return type: `Number`

`{only available when compiled with the |+timers| feature}`

`timer_start({time}, {callback} [, {options}])` `timer_start()` `timer` `timers`

Create a timer and return the timer ID.

`{time}` is the waiting time in milliseconds. This is the minimum time before invoking the callback. When the system is busy or Vim is not waiting for input the time will be longer. Zero can be used to execute the callback when Vim is back in the main loop.

`{callback}` is the function to call. It can be the name of a function or a `Funcref` . It is called with one argument, which is the timer ID. The callback is only invoked when Vim is

waiting for input.

If you want to show a message look at `popup_notification()` to avoid interfering with what the user is doing.

`{options}` is a dictionary. Supported entries:

"repeat" Number of times to repeat calling the callback. -1 means forever. When not present the callback will be called once. If the timer causes an error three times in a row the repeat is cancelled. This avoids that Vim becomes unusable because of all the error messages.

Returns -1 on error.

Example:

```
func MyHandler(timer)
 echo 'Handler called'
endfunc
let timer = timer_start(500, 'MyHandler',
 \ {'repeat': 3})
```

This will invoke `MyHandler()` three times at 500 msec intervals.

Can also be used as a `method` :

```
GetMsec()->timer_start(callback)
```

Not available in the `sandbox` .

Return type: `Number`

`{only available when compiled with the |+timers| feature}`

`timer_stop({timer})`

`timer_stop()`

Stop a timer. The timer callback will no longer be invoked. `{timer}` is an ID returned by `timer_start()`, thus it must be a `Number`. If `{timer}` does not exist there is no error.

Can also be used as a `method` :

```
GetTimer()->timer_stop()
```

Return type: `Number`

`{only available when compiled with the |+timers| feature}`

`timer_stopall()`

`timer_stopall()`

Stop all timers. The timer callbacks will no longer be invoked. Useful if a timer is misbehaving. If there are no timers there is no error.

Return type: `Number`

{only available when compiled with the |+timers| feature}

`tolower({expr})`

`tolower()`

The result is a copy of the String given, with all uppercase characters turned into lowercase (just like applying `gu` to the string). Returns an empty string on error.

Can also be used as a `method` :  
`GetText()->tolower()`

Return type: `String`

`toupper({expr})`

`toupper()`

The result is a copy of the String given, with all lowercase characters turned into uppercase (just like applying `gU` to the string). Returns an empty string on error.

Can also be used as a `method` :  
`GetText()->toupper()`

Return type: `String`

`tr({src}, {fromstr}, {tostr})`

`tr()`

The result is a copy of the `{src}` string with all characters which appear in `{fromstr}` replaced by the character in that position in the `{tostr}` string. Thus the first character in `{fromstr}` is translated into the first character in `{tostr}` and so on. Exactly like the unix "tr" command. This code also deals with multibyte characters properly.

Returns an empty string on error.

Examples:

```
echo tr("hello there", "ht", "HT")
returns "Hello THere"
echo tr("<blob>", "<>", "{}")
returns "{blob}"
```

Can also be used as a `method` :  
`GetText()->tr(from, to)`

Return type: `String`

`trim({text} [, {mask} [, {dir}]])`

`trim()`

Return `{text}` as a String where any character in `{mask}` is removed from the beginning and/or end of `{text}`.

If `{mask}` is not given, or is an empty string, `{mask}` is all characters up to `0x20`, which includes Tab, space, NL and CR, plus the non-breaking space character `0xa0`.

The optional `{dir}` argument specifies where to remove the characters:

- 0 remove from the beginning and end of `{text}`
- 1 remove only at the beginning of `{text}`
- 2 remove only at the end of `{text}`

When omitted both ends are trimmed.

This function deals with multibyte characters properly.  
Returns an empty string on error.

Examples:

```
echo trim(" some text ")
returns "some text"
echo trim(" \r\t\t\r RESERVE \t\n\x0B\xA0") .. "_TAIL"
returns "RESERVE_TAIL"
echo trim("rm<Xrm<>X>rrm", "rm<>")
returns "Xrm<>X" (characters in the middle are not removed)
echo trim(" vim ", " ", 2)
returns " vim"
```

Can also be used as a `method` :  
`GetText()->trim()`

Return type: `String`

`trunc({expr})`

`trunc()`

Return the largest integral value with magnitude less than or equal to `{expr}` as a `Float` (truncate towards zero).

`{expr}` must evaluate to a `Float` or a `Number` .

Returns 0.0 if `{expr}` is not a `Float` or a `Number` .

Examples:

```
echo trunc(1.456)
1.0
echo trunc(-5.456)
-5.0
echo trunc(4.0)
4.0
```

Can also be used as a `method` :  
`Compute()->trunc()`

Return type: `Float`

`type({expr})`

`type()`

The result is a `Number` representing the type of `{expr}`.

Instead of using the number directly, it is better to use the `v:t_` variable that has the value:

```
Number: 0 v:t_number
String: 1 v:t_string
Funcref: 2 v:t_func
List: 3 v:t_list
```

```

Dictionary: 4 v:t_dict
Float: 5 v:t_float
Boolean: 6 v:t_bool (v:false and v:true)
None: 7 v:t_none (v:null and v:none)
Job: 8 v:t_job
Channel: 9 v:t_channel
Blob: 10 v:t_blob
Class: 12 v:t_class
Object: 13 v:t_object
Typealias: 14 v:t_typealias
Enum: 15 v:t_enum
EnumValue: 16 v:t_enumvalue

```

For backward compatibility, this method can be used:

```

:if type(myvar) == type(0)
:if type(myvar) == type("")
:if type(myvar) == type(function("tr"))
:if type(myvar) == type([])
:if type(myvar) == type({})
:if type(myvar) == type(0.0)
:if type(myvar) == type(v:false)
:if type(myvar) == type(v:none)

```

To check if the v:t\_ variables exist use this:

```

:if exists('v:t_number')

```

Can also be used as a method :

```

mylist->type()

```

Return type: `Number`

`typename({expr})`

`typename()`

Return a string representation of the type of `{expr}`.

Example:

```

echo typename([1, 2, 3])
list<number>

```

Return type: `String`

`undofile({name})`

`undofile()`

Return the name of the undo file that would be used for a file with name `{name}` when writing. This uses the `'undodir'` option, finding directories that exist. It does not check if the undo file exists.

`{name}` is always expanded to the full path, since that is what is used internally.

If `{name}` is empty `undofile()` returns an empty string, since a buffer without a file name will not write an undo file.

Useful in combination with `:wundo` and `:rundo`.

When compiled without the `+persistent_undo` option this always returns an empty string.

Can also be used as a method :

```

GetFilename()->undofile()

```

Return type: `String`

`undotree([buf])`

`undotree()`

Return the current state of the undo tree for the current buffer, or for a specific buffer if `{buf}` is given. The result is a dictionary with the following items:

<code>"seq_last"</code>	The highest undo sequence number used.
<code>"seq_cur"</code>	The sequence number of the current position in the undo tree. This differs from <code>"seq_last"</code> when some changes were undone.
<code>"time_cur"</code>	Time last used for <code>:earlier</code> and related commands. Use <code>strftime()</code> to convert to something readable.
<code>"save_last"</code>	Number of the last file write. Zero when no write yet.
<code>"save_cur"</code>	Number of the current position in the undo tree.
<code>"synced"</code>	Non-zero when the last undo block was synced. This happens when waiting from input from the user. See <code>undo-blocks</code> .
<code>"entries"</code>	A list of dictionaries with information about undo blocks.

The first item in the `"entries"` list is the oldest undo item. Each List item is a `Dictionary` with these items:

<code>"seq"</code>	Undo sequence number. Same as what appears in <code>:undolist</code> .
<code>"time"</code>	Timestamp when the change happened. Use <code>strftime()</code> to convert to something readable.
<code>"newhead"</code>	Only appears in the item that is the last one that was added. This marks the last change and where further changes will be added.
<code>"curhead"</code>	Only appears in the item that is the last one that was undone. This marks the current position in the undo tree, the block that will be used by a redo command. When nothing was undone after the last change this item will not appear anywhere.
<code>"save"</code>	Only appears on the last block before a file write. The number is the write count. The first write has number 1, the last one the <code>"save_last"</code> mentioned above.
<code>"alt"</code>	Alternate entry. This is again a List of undo blocks. Each item may again have an <code>"alt"</code> item.

Return type: `dict<any>`

`uniq({list} [, {func} [, {dict}]])`

`uniq()` E882

Remove second and succeeding copies of repeated adjacent `{list}` items in-place. Returns `{list}`. If you want a list

to remain unmodified make a copy first:  
`:let newlist = uniq(copy(mylist))`

The default compare function uses the string representation of each item. For the use of `{func}` and `{dict}` see `sort()` .

Returns zero if `{list}` is not a `List` .

Can also be used as a `method` :  
`mylist->uniq()`

Return type: `list<{type}>`

`utf16idx({string}, {idx} [, {countcc} [, {charidx}]])` `utf16idx()`  
Same as `charidx()` but returns the UTF-16 code unit index of the byte at `{idx}` in `{string}` (after converting it to UTF-16).

When `{charidx}` is present and TRUE, `{idx}` is used as the character index in the String `{string}` instead of as the byte index.

An `{idx}` in the middle of a UTF-8 sequence is rounded downwards to the beginning of that sequence.

Returns -1 if the arguments are invalid or if there are less than `{idx}` bytes in `{string}`. If there are exactly `{idx}` bytes the length of the string in UTF-16 code units is returned.

See `byteidx()` and `byteidxcomp()` for getting the byte index from the UTF-16 index and `charidx()` for getting the character index from the UTF-16 index.

Refer to `string-offset-encoding` for more information.

Examples:

```
echo utf16idx('a\xff', 3) returns 2
echo utf16idx('a\xff', 7) returns 4
echo utf16idx('a\xff', 1, 0, 1) returns 2
echo utf16idx('a\xff', 2, 0, 1) returns 4
echo utf16idx('a\xc5', 6) returns 2
echo utf16idx('a\xc5', 6, 1) returns 4
echo utf16idx('a\xff', 9) returns -1
```

Can also be used as a `method` :  
`GetName()->utf16idx(idx)`

Return type: `Number`

`values({dict})` `values()`  
Return a `List` with all the values of `{dict}`. The `List` is in arbitrary order. Also see `items()` and `keys()` .  
Returns zero if `{dict}` is not a `Dict` .

Can also be used as a `method` :  
`mydict->values()`

Return type: list<any>

`virtcol({expr} [, {list} [, {winid}]])` `virtcol()`

The result is a Number, which is the screen column of the file position given with `{expr}`. That is, the last screen position occupied by the character at that position, when the screen would be of unlimited width. When there is a `<Tab>` at the position, the returned Number will be the column at the end of the `<Tab>`. For example, for a `<Tab>` in column 1, with `'ts'` set to 8, it returns 8. `conceal` is ignored. For the byte position use `col()`.

For the use of `{expr}` see `getpos()` and `col()`. When `{expr}` is `"$"`, it means the end of the cursor line, so the result is the number of cells in the cursor line plus one.

When `'virtualedit'` is used `{expr}` can be `[lnum, col, off]`, where "off" is the offset in screen columns from the start of the character. E.g., a position within a `<Tab>` or after the last character. When "off" is omitted zero is used. When Virtual editing is active in the current mode, a position beyond the end of the line can be returned. Also see `'virtualedit'`

If `{list}` is present and non-zero then `virtcol()` returns a List with the first and last screen position occupied by the character.

With the optional `{winid}` argument the values are obtained for that window instead of the current window.

**Note** that only marks in the current file can be used.

Examples:

```
" With text "foo^Lbar" and cursor on the "^L":
```

```
virtcol(".") " returns 5
virtcol(".", 1) " returns [4, 5]
virtcol("$") " returns 9
```

```
" With text " there", with 't' at 'h':
```

```
virtcol("'t") " returns 6
```

The first column is 1. 0 or `[0, 0]` is returned for an error.

A more advanced example that echoes the maximum length of all lines:

```
echo max(map(range(1, line('$')), "virtcol([v:val, '$]')))
```

Can also be used as a `method` :

```
GetPos()->virtcol()
```

Return type: `Number`

`virtcol2col({winid}, {lnum}, {col})` `virtcol2col()`

The result is a `Number`, which is the byte index of the character in window `{winid}` at buffer line `{lnum}` and virtual column `{col}`.

If buffer line `{lnum}` is an empty line, 0 is returned.

If `{col}` is greater than the last virtual column in line `{lnum}`, then the byte index of the character at the last virtual column is returned.

For a multi-byte character, the column number of the first byte in the character is returned.

The `{winid}` argument can be the window number or the `window-ID`. If this is zero, then the current window is used.

Returns -1 if the window `{winid}` doesn't exist or the buffer line `{lnum}` or virtual column `{col}` is invalid.

See also `screenpos()`, `virtcol()` and `col()`.

Can also be used as a `method` :

```
GetWinid()->virtcol2col(lnum, col)
```

Return type: `Number`

`visualmode([{expr}])` `visualmode()`

The result is a `String`, which describes the last Visual mode used in the current buffer. Initially it returns an empty string, but once Visual mode has been used, it returns "v", "V", or "<CTRL-V>" (a single **CTRL-V** character) for character-wise, line-wise, or block-wise Visual mode respectively.

Example:

```
:exe "normal " .. visualmode()
```

This enters the same Visual mode as before. It is also useful in scripts if you wish to act differently depending on the Visual mode that was used.

If Visual mode is active, use `mode()` to get the Visual mode (e.g., in a `:vmap`).

If `{expr}` is supplied and it evaluates to a non-zero `Number` or a non-empty `String`, then the Visual mode will be cleared and the old value is returned. See `non-zero-arg`.

Return type: `String`

`wildmenumode()`

`wildmenumode()`

Returns `TRUE` when the wildmenu is active and `FALSE` otherwise. See `'wildmenu'` and `'wildmode'`. This can be used in mappings to handle the `'wildcharm'` option gracefully. (Makes only sense with `mapmode-c` mappings).

For example to make `<c-j>` work like `<down>` in wildmode, use:  
`:cnoremap <expr> <C-j> wildmenu() ? "\<Down>\<Tab>" : "\<c-j>"`

(Note: this needs the `'wildcharm'` option set appropriately).

Return type: `Number`

`win_execute({id}, {command} [, {silent}])` `win_execute()`

Like ``execute()`` but in the context of window `{id}`. The window will temporarily be made the current window, without triggering autocommands or changing directory. When executing `{command}` autocommands will be triggered, this may have unexpected side effects. Use ``:noautocmd`` if needed. Example:

`call win_execute(winid, 'set syntax=python')`

Doing the same with ``setwinvar()`` would not trigger autocommands and not actually show syntax highlighting.

`E994`

Not all commands are allowed in popup windows. When window `{id}` does not exist then no error is given and an empty string is returned.

Can also be used as a `method`, the base is passed as the second argument:

`GetCommand()->win_execute(winid)`

Return type: `String`

`win_findbuf({bufnr})` `win_findbuf()`

Returns a `List` with `window-ID`s for windows that contain buffer `{bufnr}`. When there is none the list is empty.

Can also be used as a `method`:

`GetBufnr()->win_findbuf()`

Return type: `list<number>` or `list<any>`

`win_getid([win] [, {tab}])` `win_getid()`

Get the `window-ID` for the specified window.

When `{win}` is missing use the current window.

With `{win}` this is the window number. The top window has number 1.

Without `{tab}` use the current tab, otherwise the tab with number `{tab}`. The first tab has number one.

Return zero if the window cannot be found.

Can also be used as a `method` :  
`GetWinnr()->win_getid()`

Return type: `Number`

`win_gettype([{nr}])` `win_gettype()`

Return the type of the window:

"autocmd"	autocommand window. Temporary window used to execute autocommands.
"command"	command-line window <code>cmdwin</code>
(empty)	normal window
"loclist"	<code>location-list-window</code>
"popup"	popup window <code>popup</code>
"preview"	preview window <code>preview-window</code>
"quickfix"	<code>quickfix-window</code>
"unknown"	window <code>{nr}</code> not found

When `{nr}` is omitted return the type of the current window.  
When `{nr}` is given return the type of this window by number or `window-ID` .

Also see the `'buftype'` option. When running a terminal in a popup window then `'buftype'` is "terminal" and `win_gettype()` returns "popup".

Can also be used as a `method` :  
`GetWinid()->win_gettype()`

Return type: `String`

`win_gotoid({expr})` `win_gotoid()`

Go to window with ID `{expr}`. This may also change the current tabpage.

Return TRUE if successful, FALSE if the window cannot be found.

Can also be used as a `method` :  
`GetWinid()->win_gotoid()`

Return type: `Number`

`win_id2tabwin({expr})` `win_id2tabwin()`

Return a list with the tab number and window number of window with ID `{expr}`: `[tabnr, winnr]`.

Return `[0, 0]` if the window cannot be found.

Can also be used as a `method` :  
`GetWinid()->win_id2tabwin()`

Return type: `list<number>`

`win_id2win({expr})` `win_id2win()`  
Return the window number of window with ID `{expr}`.  
Return 0 if the window cannot be found in the current tabpage.

Can also be used as a `method` :  
`GetWinid()->win_id2win()`

Return type: `Number`

`win_move_separator({nr}, {offset})` `win_move_separator()`  
Move window `{nr}`'s vertical separator (i.e., the right border) by `{offset}` columns, as if being dragged by the mouse. `{nr}` can be a window number or `window-ID`. A positive `{offset}` moves right and a negative `{offset}` moves left. Moving a window's vertical separator will change the width of the window and the width of other windows adjacent to the vertical separator. The magnitude of movement may be smaller than specified (e.g., as a consequence of maintaining `'winminwidth'`). Returns TRUE if the window can be found and FALSE otherwise.  
This will fail for the rightmost window and a full-width window, since it has no separator on the right.  
Only works for the current tab page. `E1308`

Can also be used as a `method` :  
`GetWinnr()->win_move_separator(offset)`

Return type: `Number`

`win_move_statusline({nr}, {offset})` `win_move_statusline()`  
Move window `{nr}`'s status line (i.e., the bottom border) by `{offset}` rows, as if being dragged by the mouse. `{nr}` can be a window number or `window-ID`. A positive `{offset}` moves down and a negative `{offset}` moves up. Moving a window's status line will change the height of the window and the height of other windows adjacent to the status line. The magnitude of movement may be smaller than specified (e.g., as a consequence of maintaining `'winminheight'`). Returns TRUE if the window can be found and FALSE otherwise.  
Only works for the current tab page.

Can also be used as a `method` :  
`GetWinnr()->win_move_statusline(offset)`

Return type: `Number`

`win_screenpos({nr})` `win_screenpos()`  
Return the screen position of window `{nr}` as a list with two numbers: `[row, col]`. The first window always has position `[1, 1]`, unless there is a tabline, then it is `[2, 1]`.  
`{nr}` can be the window number or the `window-ID`. Use zero

for the current window.  
Returns [0, 0] if the window cannot be found.

Can also be used as a `method` :  
`GetWinid()->win_screenpos()`

Return type: `list<number>`

`win_splitmove({nr}, {target} [, {options}])` `win_splitmove()`  
Temporarily switch to window `{target}`, then move window `{nr}` to a new split adjacent to `{target}`. Unlike commands such as `:split`, no new windows are created (the `window-ID` of window `{nr}` is unchanged after the move).

Both `{nr}` and `{target}` can be window numbers or `window-ID` s. Both must be in the current tab page.

Returns zero for success, non-zero for failure.

`{options}` is a `Dictionary` with the following optional entries:

- "vertical" When TRUE, the split is created vertically, like with `:vsplit`.
- "rightbelow" When TRUE, the split is made below or to the right (if vertical). When FALSE, it is done above or to the left (if vertical). When not present, the values of `'splitbelow'` and `'splitright'` are used.

Can also be used as a `method` :  
`GetWinid()->win_splitmove(target)`

Return type: `Number`

`winbufnr({nr})` `winbufnr()`  
The result is a `Number`, which is the number of the buffer associated with window `{nr}`. `{nr}` can be the window number or the `window-ID`. When `{nr}` is zero, the number of the buffer in the current window is returned.

When window `{nr}` doesn't exist, -1 is returned.

Example:

```
:echo "The file in the current window is " . bufname(winbufnr(0))
```

Can also be used as a `method` :  
`FindWindow()->winbufnr()->bufname()`

Return type: `Number`

`wincol()` `wincol()`  
The result is a `Number`, which is the virtual column of the cursor in the window. This is counting screen cells from the

left side of the window. The leftmost column is one.

Return type: `Number`

`windowsversion()`

`windowsversion()`

The result is a String. For MS-Windows it indicates the OS version. E.g, Windows 10 is "10.0", Windows 8 is "6.2", Windows XP is "5.1". For non-MS-Windows systems the result is an empty string.

Return type: `String`

`winheight({nr})`

`winheight()`

The result is a Number, which is the height of window `{nr}`. `{nr}` can be the window number or the `window-ID`.

When `{nr}` is zero, the height of the current window is returned. When window `{nr}` doesn't exist, -1 is returned.

An existing window always has a height of zero or more.

This excludes any window toolbar line.

Examples:

```
:echo "The current window has " .. winheight(0) .. " lines."
```

Can also be used as a `method` :

```
GetWinid()->winheight()
```

Return type: `Number`

`winlayout([{{tabnr}}])`

`winlayout()`

The result is a nested List containing the layout of windows in a tabpage.

Without `{tabnr}` use the current tabpage, otherwise the tabpage with number `{tabnr}`. If the tabpage `{tabnr}` is not found, returns an empty list.

For a leaf window, it returns:

```
['leaf', {winid}]
```

For horizontally split windows, which form a column, it returns:

```
['col', [{nested list of windows}]]
```

For vertically split windows, which form a row, it returns:

```
['row', [{nested list of windows}]]
```

Example:

```
" Only one window in the tab page
```

```
:echo winlayout()
```

```
['leaf', 1000]
```

```
" Two horizontally split windows
```

```
:echo winlayout()
```

```
['col', [['leaf', 1000], ['leaf', 1001]]]
```

```
" The second tab page, with three horizontally split
```

```

" windows, with two vertically split windows in the
" middle window
:echo winlayout(2)
['col', [['leaf', 1002], ['row', [['leaf', 1003],
 ['leaf', 1001]]], ['leaf', 1000]]]

```

Can also be used as a `method` :  
`GetTabnr()->winlayout()`

Return type: `list<any>`

`winline()`

`winline()`

The result is a Number, which is the screen line of the cursor in the window. This is counting screen lines from the top of the window. The first line is one. If the cursor was moved the view on the file will be updated first, this may cause a scroll.

Return type: `Number`

`winnr([arg])`

`winnr()`

The result is a Number, which is the number of the current window. The top window has number 1. Returns zero for a popup window.

The optional argument `{arg}` supports the following values:

- `$` the number of the last window (the window count).
- `#` the number of the last accessed window (where `CTRL-W_p` goes to). If there is no previous window or it is in another tab page 0 is returned. May refer to the current window in some cases (e.g. when evaluating `'statusline'` expressions).
- `{N}j` the number of the Nth window below the current window (where `CTRL-W_j` goes to).
- `{N}k` the number of the Nth window above the current window (where `CTRL-W_k` goes to).
- `{N}h` the number of the Nth window left of the current window (where `CTRL-W_h` goes to).
- `{N}l` the number of the Nth window right of the current window (where `CTRL-W_l` goes to).

The number can be used with `CTRL-W_w` and `":wincmd w"` `:wincmd` .

When `{arg}` is invalid an error is given and zero is returned. Also see `tabpagewinnr()` and `win_getid()` .

Examples:

```

let window_count = winnr('$')
let prev_window = winnr('#')
let wnum = winnr('3k')

```

Can also be used as a `method` :

`GetWinval()->winnr()`

Return type: `Number`

`winrestcmd()` `winrestcmd()`

Returns a sequence of `:resize` commands that should restore the current window sizes. Only works properly when no windows are opened or closed and the current window and tab page is unchanged.

Example:

```
:let cmd = winrestcmd()
:call MessWithWindowSizes()
:exe cmd
```

Return type: `String`

`winrestview({dict})` `winrestview()`

Uses the `Dictionary` returned by `winsaveview()` to restore the view of the current window.

**Note:** The `{dict}` does not have to contain all values, that are returned by `winsaveview()`. If values are missing, those settings won't be restored. So you can use:

```
:call winrestview({'curswant': 4})
```

This will only set the `curswant` value (the column the cursor wants to move on vertical movements) of the cursor to column 5 (yes, that is 5), while all other settings will remain the same. This is useful, if you set the cursor position manually.

If you have changed the values the result is unpredictable. If the window size changed the result won't be the same.

Can also be used as a `method` :

```
GetView()->winrestview()
```

Return type: `Number`

`winsaveview()` `winsaveview()`

Returns a `Dictionary` that contains information to restore the view of the current window. Use `winrestview()` to restore the view.

This is useful if you have a mapping that jumps around in the buffer and you want to go back to the original view.

This does not save fold information. Use the **'foldenable'** option to temporarily switch off folding, so that folds are not opened when moving around. This may have side effects.

The return value includes:

<code>lnum</code>	cursor line number
<code>col</code>	cursor column (Note: the first column zero, as opposed to what <code>getcurpos()</code> returns)

coladd	cursor column offset for <b>'virtualedit'</b>
curswant	column for vertical movement (Note: the first column is zero, as opposed to what <code>getcurpos()</code> returns). After <code>\$</code> command it will be a very large number equal to <code>v:maxcol</code> .
topline	first line in the window
topfill	filler lines, only in diff mode
leftcol	first column displayed; only used when <b>'wrap'</b> is off
skipcol	columns skipped

**Note** that no option values are saved.

Return type: dict<number>

`winwidth({nr})`

`winwidth()`

The result is a Number, which is the width of window `{nr}`. `{nr}` can be the window number or the `window-ID` . When `{nr}` is zero, the width of the current window is returned. When window `{nr}` doesn't exist, -1 is returned. An existing window always has a width of zero or more.

Examples:

```
:echo "The current window has " .. winwidth(0) .. " columns."
:if winwidth(0) <= 50
: 50 wincmd |
:endif
```

For getting the terminal or screen size, see the **'columns'** option.

Can also be used as a `method` :  
`GetWinid()->winwidth()`

Return type: `Number`

`wordcount()`

`wordcount()`

The result is a dictionary of byte/chars/word statistics for the current buffer. This is the same info as provided by `g_CTRL-G`

The return value includes:

bytes	Number of bytes in the buffer
chars	Number of chars in the buffer
words	Number of words in the buffer
cursor_bytes	Number of bytes before cursor position (not in Visual mode)
cursor_chars	Number of chars before cursor position (not in Visual mode)
cursor_words	Number of words before cursor position (not in Visual mode)
visual_bytes	Number of bytes visually selected (only in Visual mode)
visual_chars	Number of chars visually selected (only in Visual mode)

visual\_words      Number of words visually selected  
                    (only in Visual mode)

Return type: dict<number>

`writefile({object}, {fname} [, {flags}])`      `writefile()`  
When `{object}` is a `List` write it to file `{fname}`. Each list item is separated with a NL. Each list item must be a String or Number.  
All NL characters are replaced with a NUL character.  
Inserting CR characters needs to be done before passing `{list}` to `writefile()`.

When `{object}` is a `Blob` write the bytes to file `{fname}` unmodified, also when binary mode is not specified.

`{flags}` must be a String. These characters are recognized:

'b' Binary mode is used: There will not be a NL after the last list item. An empty item at the end does cause the last line in the file to end in a NL.

'a' Append mode is used, lines are appended to the file:  
    `:call writefile(["foo"], "event.log", "a")`  
    `:call writefile(["bar"], "event.log", "a")`

'D' Delete the file when the current function ends. This works like:  
    `:defer delete({fname})`  
Fails when not in a function. Also see `:defer` .

's' `fsync()` is called after writing the file. This flushes the file to disk, if possible. This takes more time but avoids losing the file if the system crashes.

'S' `fsync()` is not called, even when `'fsync'` is set.

When `{flags}` does not contain "S" or "s" then `fsync()` is called if the `'fsync'` option is set.

An existing file is overwritten, if possible.

When the write fails -1 is returned, otherwise 0. There is an error message if the file can't be created or when writing fails.

Also see `readfile()` .

To copy a file byte for byte:

```
:let fl = readfile("foo", "b")
:call writefile(fl, "foocopy", "b")
```

Can also be used as a `method` :

```
GetText()->writefile("thefile")
```

Return type: `Number`

`xor({expr}, {expr})` `xor()`  
Bitwise XOR on the two arguments. The arguments are converted to a number. A List, Dict or Float argument causes an error. Also see ``and()`` and ``or()``.  
Example:

```
:let bits = xor(bits, 0x80)
```

Can also be used as a `method` :

```
:let bits = bits->xor(0x80)
```

Return type: `Number`

---

### 3. Feature list

`feature-list`

There are three types of features:

1. Features that are only supported when they have been enabled when Vim was compiled `+feature-list` . Example:

```
:if has("cindent")
```

2. Features that are only supported when certain conditions have been met. Example:

```
:if has("gui_running")
```

3. Beyond a certain version or at a certain version and including a specific patch. The "patch-7.4.248" feature means that the `Vim version is` 7.5 or later, or it is version 7.4 and patch 248 was included. Example:

```
:if has("patch-7.4.248")
```

**Note** that it's possible for patch 248 to be omitted even though 249 is included. Only happens when cherry-picking patches.

**Note** that this form only works for patch 7.4.237 and later, before that you need to check for the patch and the `v:version`. Example (checking version 6.2.148 or later):

```
:if v:version > 602 || (v:version == 602 && has("patch148"))
```

Hint: To find out if Vim supports backslashes in a file name (MS-Windows), use: ``if exists('+shellslash')``

<code>acl</code>	Compiled with <code>ACL</code> support.
<code>all_builton_terms</code>	Compiled with all builtin terminals enabled. (always true)
<code>amiga</code>	Amiga version of Vim.
<code>arabic</code>	Compiled with Arabic support <code>Arabic</code> .
<code>arp</code>	Compiled with ARP support (Amiga).
<code>autocmd</code>	Compiled with autocommand support. (always true)
<code>autochdir</code>	Compiled with support for <code>'autochdir'</code>
<code>autoservername</code>	Automatically enable <code>clientserver</code>
<code>balloon_eval</code>	Compiled with <code>balloon-eval</code> support.
<code>balloon_multiline</code>	GUI supports multiline balloons.

beos	BeOS version of Vim.
browse	Compiled with <code>:browse</code> support, and <code>browse()</code> will work.
browsefilter	Compiled with support for <code>browsefilter</code> .
bsd	Compiled on an OS in the BSD family (excluding macOS).
builtin_terms	Compiled with some builtin terminals. (always true)
byte_offset	Compiled with support for 'o' in ' <code>statusline</code> '
channel	Compiled with support for <code>channel</code> and <code>job</code>
cindent	Compiled with ' <code>cindent</code> ' support. (always true)
clientserver	Compiled with remote invocation support <code>clientserver</code> .
clipboard	Compiled with ' <code>clipboard</code> ' support.
clipboard_working	Compiled with ' <code>clipboard</code> ' support and it can be used.
cmdline_compl	Compiled with <code>cmdline-completion</code> support.
cmdline_hist	Compiled with <code>cmdline-history</code> support.
cmdline_info	Compiled with ' <code>showcmd</code> ' and ' <code>ruler</code> ' support.
comments	Compiled with ' <code>comments</code> ' support.
compatible	Compiled to be very Vi compatible.
conpty	Platform where <code>ConPTY</code> can be used.
cryptv	Compiled with encryption support <code>encryption</code> .
cscope	Compiled with <code>cscope</code> support.
cursorbind	Compiled with ' <code>cursorbind</code> ' (always true)
debug	Compiled with "DEBUG" defined.
dialog_con	Compiled with console dialog support.
dialog_con_gui	Compiled with console and GUI dialog support.
dialog_gui	Compiled with GUI dialog support.
diff	Compiled with <code>vimdiff</code> and ' <code>diff</code> ' support.
digraphs	Compiled with support for digraphs.
directx	Compiled with support for DirectX and ' <code>renderoptions</code> '.
dnd	Compiled with support for the "~" register <code>quote_~</code> .
drop_file	Compiled with <code>drop_file</code> support.
ebcdic	Compiled on a machine with ebcdic character set.
emacs_tags	Compiled with support for Emacs tags.
eval	Compiled with expression evaluation support. Always true, of course!
ex_extra	<code>+ex_extra</code> (always true)
extra_search	Compiled with support for ' <code>incsearch</code> ' and ' <code>hlsearch</code> '
farsi	Support for Farsi was removed <code>farsi</code> .
file_in_path	Compiled with support for <code>gf</code> and <code>&lt;cfil&gt;</code> (always true)
filterpipe	When ' <code>shelltemp</code> ' is off pipes are used for shell read/write/filter commands
find_in_path	Compiled with support for include file searches <code>+find_in_path</code> .
float	Compiled with support for <code>Float</code> .
fname_case	Case in file names matters (for Amiga and MS-Windows this is not present).
folding	Compiled with <code>folding</code> support.
footer	Compiled with GUI footer support. <code>gui-footer</code>
fork	Compiled to use <code>fork()/exec()</code> instead of <code>system()</code> .
gettext	Compiled with message translation <code>multi-lang</code>
gui	Compiled with GUI enabled.
gui_athena	Compiled with Athena GUI (always false).
gui_gnome	Compiled with Gnome support ( <code>gui_gtk</code> is also defined).

gui_gtk	Compiled with GTK+ GUI (any version).
gui_gtk2	Compiled with GTK+ 2 GUI (gui_gtk is also defined).
gui_gtk3	Compiled with GTK+ 3 GUI (gui_gtk is also defined).
gui_haiku	Compiled with Haiku GUI.
gui_mac	Compiled with Macintosh GUI.
gui_motif	Compiled with Motif GUI.
gui_photon	Compiled with Photon GUI.
gui_running	Vim is running in the GUI, or it will start soon.
gui_win32	Compiled with MS-Windows Win32 GUI.
gui_win32s	idem, and Win32s system being used (Windows 3.1)
haiku	Haiku version of Vim.
hangel_input	Compiled with Hangel input support. <a href="#">hangel</a>
hpux	HP-UX version of Vim.
hurd	GNU/Hurd version of Vim
iconv	Can use iconv() for conversion.
insert_expand	Compiled with support for <b>CTRL-X</b> expansion commands in Insert mode. (always true)
job	Compiled with support for <a href="#">channel</a> and <a href="#">job</a>
ipv6	Compiled with support for IPV6 networking in <a href="#">channel</a> .
jumplist	Compiled with <a href="#">jumplist</a> support. (always true)
keymap	Compiled with ' <a href="#">keymap</a> ' support.
lambda	Compiled with <a href="#">lambda</a> support.
langmap	Compiled with ' <a href="#">langmap</a> ' support.
libcall	Compiled with <a href="#">libcall()</a> support.
linebreak	Compiled with ' <a href="#">linebreak</a> ', ' <a href="#">breakat</a> ', ' <a href="#">showbreak</a> ' and ' <a href="#">breakindent</a> ' support.
linux	Linux version of Vim.
lispindent	Compiled with support for lisp indenting. (always true)
listcmds	Compiled with commands for the buffer list <a href="#">:files</a> and the argument list <a href="#">arglist</a> .
localmap	Compiled with local mappings and abbr. <a href="#">:map-local</a>
lua	Compiled with Lua interface <a href="#">Lua</a> .
mac	Any Macintosh version of Vim cf. osx
macunix	Synonym for osxdarwin
menu	Compiled with support for <a href="#">:menu</a> .
mksession	Compiled with support for <a href="#">:mksession</a> .
modify_fname	Compiled with file name modifiers. <a href="#">filename-modifiers</a> (always true)
mouse	Compiled with support for mouse.
mouse_dec	Compiled with support for Dec terminal mouse.
mouse_gpm	Compiled with support for gpm (Linux console mouse)
mouse_gpm_enabled	GPM mouse is working
mouse_netterm	Compiled with support for netterm mouse.
mouse_pterm	Compiled with support for qnx pterm mouse.
mouse_sysmouse	Compiled with support for sysmouse (*BSD console mouse)
mouse_sgr	Compiled with support for sgr mouse.
mouse_urxvt	Compiled with support for urxvt mouse.
mouse_xterm	Compiled with support for xterm mouse.
mousethape	Compiled with support for ' <a href="#">mousethape</a> '.
multi_byte	Compiled with support for ' <a href="#">encoding</a> ' (always true)
multi_byte_encoding	<a href="#">'encoding'</a> is set to a multibyte encoding.
multi_byte_ime	Compiled with support for IME input method.
multi_lang	Compiled with support for multiple languages.

mzscheme	Compiled with MzScheme interface <a href="#">mzscheme</a> .
nanotime	Compiled with sub-second time stamp checks.
netbeans_enabled	Compiled with support for <a href="#">netbeans</a> and connected.
netbeans_intg	Compiled with support for <a href="#">netbeans</a> .
num64	Compiled with 64-bit <a href="#">Number</a> support. (always true)
ole	Compiled with OLE automation support for Win32.
osx	Compiled for macOS cf. mac
osxdarwin	Compiled for macOS, with <a href="#">mac-darwin-feature</a>
packages	Compiled with <a href="#">packages</a> support.
path_extra	Compiled with up/downwards search in <b>'path'</b> and <b>'tags'</b>
perl	Compiled with Perl interface.
persistent_undo	Compiled with support for persistent undo history.
postscript	Compiled with PostScript file printing.
printer	Compiled with <a href="#">:hardcopy</a> support.
profile	Compiled with <a href="#">:profile</a> support.
prof_nsec	Profile results are in nanoseconds.
python	Python 2.x interface available. <a href="#">has-python</a>
python_compiled	Compiled with Python 2.x interface. <a href="#">has-python</a>
python_dynamic	Python 2.x interface is dynamically loaded. <a href="#">has-python</a>
python3	Python 3.x interface available. <a href="#">has-python</a>
python3_compiled	Compiled with Python 3.x interface. <a href="#">has-python</a>
python3_dynamic	Python 3.x interface is dynamically loaded. <a href="#">has-python</a>
python3_stable	Python 3.x interface is using Python Stable ABI. <a href="#">has-python</a>
pythonx	Python 2.x and/or 3.x interface available. <a href="#">python_x</a>
qnx	QNX version of Vim.
quickfix	Compiled with <a href="#">quickfix</a> support.
reltime	Compiled with <a href="#">reltime()</a> support.
rightleft	Compiled with <b>'rightleft'</b> support.
ruby	Compiled with Ruby interface <a href="#">ruby</a> .
scrollbind	Compiled with <b>'scrollbind'</b> support. (always true)
showcmd	Compiled with <b>'showcmd'</b> support.
signs	Compiled with <a href="#">:sign</a> support.
smartindent	Compiled with <b>'smartindent'</b> support. (always true)
sodium	Compiled with libsodium for better crypt support
sound	Compiled with sound support, e.g. <code>`sound_playevent()</code>
spell	Compiled with spell checking support <a href="#">spell</a> .
startuptime	Compiled with <a href="#">--startuptime</a> support.
statusline	Compiled with support for <b>'statusline'</b> , <b>'rulerformat'</b> and special formats of <b>'titlestring'</b> and <b>'iconstring'</b> .
sun	SunOS version of Vim.
sun_workshop	Support for Sun <a href="#">workshop</a> has been removed.
syntax	Compiled with syntax highlighting support <a href="#">syntax</a> .
syntax_items	There are active syntax highlighting items for the current buffer.
system	Compiled to use system() instead of fork()/exec().
tag_binary	Compiled with binary searching in tags files <a href="#">tag-binary-search</a> . (always true)
tag_old_static	Support for old static tags was removed, see <a href="#">tag-old-static</a> .
tcl	Compiled with Tcl interface.
termguicolors	Compiled with true color in terminal support.
terminal	Compiled with <a href="#">terminal</a> support.
terminfo	Compiled with terminfo instead of termcap.
termresponse	Compiled with support for <a href="#">t_RV</a> and <a href="#">v:termresponse</a> .

textobjects           Compiled with support for `text-objects` .  
textprop              Compiled with support for `text-properties` .  
tgetent               Compiled with tgetent support, able to use a termcap  
                      or terminfo file.  
timers                 Compiled with `timer_start()` support.  
title                  Compiled with window title support `'title'` .  
                      (always true)  
toolbar                Compiled with support for `gui-toolbar` .  
ttyin                  input is a terminal (tty)  
ttyout                 output is a terminal (tty)  
unix                   Unix version of Vim. `+unix`  
unnamedplus           Compiled with support for "unnamedplus" in `'clipboard'`  
user\_commands         User-defined commands. (always true)  
vartabs                Compiled with variable tabstop support `'vartabstop'` .  
vcon                   Win32: Virtual console support is working, can use  
                      `'termguicolors'`. Also see `+vtp` .  
vertsplitted          Compiled with vertically split windows `:vsplit` .  
                      (always true)  
vim\_starting           True while initial source'ing takes place. `startup`  
                      `vim_starting`  
vim9script             Compiled with `Vim9` script support  
viminfo                Compiled with viminfo support.  
vimscrip-1            Compiled Vim script version 1 support  
vimscrip-2            Compiled Vim script version 2 support  
vimscrip-3            Compiled Vim script version 3 support  
vimscrip-4            Compiled Vim script version 4 support  
virtualedit           Compiled with `'virtualedit'` option. (always true)  
visual                 Compiled with Visual mode. (always true)  
visualextra           Compiled with extra Visual mode commands. (always  
                      true) `blockwise-operators` .  
vms                    VMS version of Vim.  
vreplace              Compiled with `gR` and `gr` commands. (always true)  
vtp                    Compiled for vcon support `+vtp` (check vcon to find  
                      out if it works in the current console).  
wildignore            Compiled with `'wildignore'` option.  
wildmenu              Compiled with `'wildmenu'` option.  
win16                  old version for MS-Windows 3.1 (always false)  
win32                  Win32 version of Vim (MS-Windows 95 and later, 32 or  
                      64 bits)  
win32unix             Win32 version of Vim, using Unix files (Cygwin)  
win64                  Win64 version of Vim (MS-Windows 64 bit).  
win95                  Win32 version for MS-Windows 95/98/ME (always false)  
winaltkeys            Compiled with `'winaltkeys'` option.  
windows                Compiled with support for more than one window.  
                      (always true)  
writebackup           Compiled with `'writebackup'` default on.  
xattr                  Compiled with extended attributes support `xattr`  
                      (currently only supported on Linux).  
xfontset              Compiled with X fontset support `xfontset` .  
xim                    Compiled with X input method support `xim` .  
xpm                    Compiled with pixmap support.  
xpm\_w32                Compiled with pixmap support for Win32. (Only for  
                      backward compatibility. Use "xpm" instead.)  
xsmp                   Compiled with X session management support.

xsmg_interact	Compiled with interactive X session management support.
xterm_clipboard	Compiled with support for xterm clipboard.
xterm_save	Compiled with support for saving and restoring the xterm screen.
x11	Compiled with X11 support.

---

#### 4. Matching a pattern in a String

string-match

This is common between several functions. A regexp pattern as explained at [pattern](#) is normally used to find a match in the buffer lines. When a pattern is used to find a match in a String, almost everything works in the same way. The difference is that a String is handled like it is one line. When it contains a "\n" character, this is not seen as a line break for the pattern. It can be matched with a "\n" in the pattern, or with ".". Example:

```
:let a = "aaaa\nxxxx"
:echo matchstr(a, "..\n..")
aa
xx
:echo matchstr(a, "a.x")
a
x
```

Don't forget that "^" will only match at the first character of the String and "\$" at the last character of the string. They don't match after or before a "\n".

## Inter-process communication

channel

Vim uses channels to communicate with other processes.

A channel uses a socket or pipes.

socket-interface

Jobs can be used to start processes and communicate with them.

The Netbeans interface also uses a channel. netbeans

- |                                      |                           |

E1277

{only when compiled with the |+channel| feature for channel stuff}

You can check this with: ``has('channel')``

{only when compiled with the |+job| feature for job stuff}

You can check this with: ``has('job')``

## =====

job-channel-overview

There are four main types of jobs:

1. A daemon, serving several Vim instances.  
Vim connects to it with a socket.
2. One job working with one Vim instance, asynchronously.  
Uses a socket or pipes.
3. A job performing some work for a short time, asynchronously.  
Uses a socket or pipes.
4. Running a filter, synchronously.  
Uses pipes.

For when using sockets See [job-start](#) , [job-start-nochannel](#) and [channel-open](#) . For 2 and 3, one or more jobs using pipes, see [job-start](#) . For 4 use the `":{range}!cmd"` command, see [filter](#) .

Over the socket and pipes these protocols are available:

RAW nothing known, Vim cannot tell where a message ends

NL every message ends in a NL (newline) character  
JSON JSON encoding `json_encode()`  
JS JavaScript style JSON-like encoding `js_encode()`  
LSP Language Server Protocol encoding `language-server-protocol`

Common combination are:

- Using a job connected through pipes in NL mode. E.g., to run a style checker and receive errors and warnings.
- Using a daemon, connecting over a socket in JSON mode. E.g. to lookup cross-references in a database.

---

## 2. Channel demo

`channel-demo` `demoserver.py`

This requires Python. The demo program can be found in  
\$VIMRUNTIME/tools/demoserver.py  
Run it in one terminal. We will call this T1.

Run Vim in another terminal. Connect to the demo server with:  
`let channel = ch_open('localhost:8765')`

In T1 you should see:

```
=== socket opened ===
```

You can now send a message to the server:

```
echo ch_evalexpr(channel, 'hello!')
```

The message is received in T1 and a response is sent back to Vim.  
You can see the raw messages in T1. What Vim sends is:

```
[1,"hello!"]
```

And the response is:

```
[1,"got it"]
```

The number will increase every time you send a message.

The server can send a command to Vim. Type this on T1 (literally, including the quotes):

```
["ex","echo 'hi there'"]
```

And you should see the message in Vim. You can move the cursor a word forward:

```
["normal","w"]
```

To handle asynchronous communication a callback needs to be used:

```
func MyHandler(channel, msg)
 echo "from the handler: " .. a:msg
endfunc
call ch_sendexpr(channel, 'hello!', {'callback': "MyHandler"})
```

Vim will not wait for a response. Now the server can send the response later and MyHandler will be invoked.

Instead of giving a callback with every send call, it can also be specified when opening the channel:

```
call ch_close(channel)
let channel = ch_open('localhost:8765', {'callback': "MyHandler"})
call ch_sendexpr(channel, 'hello channel!')
```

When trying out channels it's useful to see what is going on. You can tell Vim to write lines in log file:

```
 call ch_logfile('channellog', 'w')
See ch_logfile() .
```

---

### 3. Opening a channel

channel-open

To open a channel:

```
let channel = ch_open({address} [, {options}])
if ch_status(channel) == "open"
 " use the channel
```

Use `ch_status()` to see if the channel could be opened.

channel-address

`{address}` can be a domain name or an IP address, followed by a port number, or a Unix-domain socket path prefixed by "unix:". E.g.

```
www.example.com:80 " domain + port
127.0.0.1:1234 " IPv4 + port
[2001:db8::1]:8765 " IPv6 + port
unix:/tmp/my-socket " Unix-domain socket path
```

`{options}` is a dictionary with optional entries:

channel-open-options

"mode" can be:

channel-mode

```
"json" - Use JSON, see below; most convenient way. Default.
"js" - Use JS (JavaScript) encoding, more efficient than JSON.
"nl" - Use messages that end in a NL character
"raw" - Use raw messages
"lsp" - Use language server protocol encoding
```

channel-callback E921

"callback" A function that is called when a message is received that is not handled otherwise (e.g. a JSON message with ID zero). It gets two arguments: the channel and the received message. Example:

```
func Handle(channel, msg)
 echo 'Received: ' .. a:msg
endfunc
let channel = ch_open("localhost:8765", {"callback": "Handle"})
```

When "mode" is "json" or "js" or "lsp" the "msg" argument is the body of the received message, converted to Vim types.

When "mode" is "nl" the "msg" argument is one message, excluding the NL.

When "mode" is "raw" the "msg" argument is the whole message as a string.

For all callbacks: Use `function()` to bind it to arguments and/or a Dictionary. Or use the form "dict.function" to bind the Dictionary.

Callbacks are only called at a "safe" moment, usually when Vim is waiting for the user to type a character. Vim does not use

multi-threading.

- close\_cb**
- "close\_cb" A function that is called when the channel gets closed, other than by calling `ch_close()`. It should be defined like this:
- ```
func MyCloseHandler(channel)
    Vim will invoke callbacks that handle data before invoking
    close_cb, thus when this function is called no more data will
    be passed to the callbacks. However, if a callback causes Vim
    to check for messages, the close_cb may be invoked while still
    in the callback. The plugin must handle this somehow, it can
    be useful to know that no more data is coming.
    If it is not known if there is a message to be read, use a
    try/catch block:
        try
            let msg = ch_readraw(a:channel)
        catch
            let msg = 'no message'
        endtry
        try
            let err = ch_readraw(a:channel, #{part: 'err'})
        catch
            let err = 'no error'
        endtry
```
- channel-drop**
- "drop" Specifies when to drop messages:
- "auto" When there is no callback to handle a message. The "close_cb" is also considered for this.
 - "never" All messages will be kept.
- channel-noblock**
- "noblock" Same effect as `job-noblock` . Only matters for writing.
- waittime**
- "waittime" The time to wait for the connection to be made in milliseconds. A negative number waits forever.
- The default is zero, don't wait, which is useful if a local server is supposed to be running already. On Unix Vim actually uses a 1 msec timeout, that is required on many systems. Use a larger value for a remote server, e.g. 10 msec at least.
- channel-timeout**
- "timeout" The time to wait for a request when blocking, E.g. when using `ch_evalexpr()`. In milliseconds. The default is 2000 (2 seconds).

When "mode" is "json" or "js" the "callback" is optional. When omitted it is only possible to receive a message after sending one.

To change the channel options after opening it use `ch_setoptions()` . The arguments are similar to what is passed to `ch_open()` , but "waittime" cannot be given, since that only applies to opening the channel.

For example, the handler can be added or changed:

```
call ch_setoptions(channel, {'callback': callback})
```

When "callback" is empty (zero or an empty string) the handler is removed.

After a callback has been invoked Vim will update the screen and put the cursor back where it belongs. Thus the callback should not need to do `:redraw``.

The timeout can be changed:

```
call ch_setoptions(channel, {'timeout': msec})
```

channel-close E906

Once done with the channel, disconnect it like this:

```
call ch_close(channel)
```

When a socket is used this will close the socket for both directions. When pipes are used (stdin/stdout/stderr) they are all closed. This might not be what you want! Stopping the job with `job_stop()` might be better. All readahead is discarded, callbacks will no longer be invoked.

Note that a channel is closed in three stages:

- The I/O ends, log message: "Closing channel". There can still be queued messages to read or callbacks to invoke.
- The readahead is cleared, log message: "Clearing channel". Some variables may still reference the channel.
- The channel is freed, log message: "Freeing channel".

When the channel can't be opened you will get an error message. There is a difference between MS-Windows and Unix: On Unix when the port doesn't exist `ch_open()` fails quickly. On MS-Windows "waittime" applies.

E898 E901 E902

If there is an error reading or writing a channel it will be closed.

E630 E631

4. Using a JSON or JS channel

channel-use

If mode is JSON then a message can be sent synchronously like this:

```
let response = ch_evalexpr(channel, {expr})
```

This awaits a response from the other side.

When mode is JS this works the same, except that the messages use JavaScript encoding. See `js_encode()` for the difference.

To send a message, without handling a response or letting the channel callback handle the response:

```
call ch_sendexpr(channel, {expr})
```

To send a message and letting the response handled by a specific function, asynchronously:

```
call ch_sendexpr(channel, {expr}, {'callback': Handler})
```

Vim will match the response with the request using the message ID. Once the response is received the callback will be invoked. Further responses with the

same ID will be ignored. If your server sends back multiple responses you need to send them with ID zero, they will be passed to the channel callback.

The `{expr}` is converted to JSON and wrapped in an array. An example of the message that the receiver will get when `{expr}` is the string "hello":

```
[12,"hello"]
```

The format of the JSON sent is:

```
[{number},{expr}]
```

In which `{number}` is different every time. It must be used in the response (if any):

```
[{number},{response}]
```

This way Vim knows which sent message matches with which received message and can call the right handler. Also when the messages arrive out of order.

A newline character is terminating the JSON text. This can be used to separate the read text. For example, in Python:

```
splitidx = read_text.find('\n')
message = read_text[:splitidx]
rest = read_text[splitidx + 1:]
```

The sender must always send valid JSON to Vim. Vim can check for the end of the message by parsing the JSON. It will only accept the message if the end was received. A newline after the message is optional.

When the process wants to send a message to Vim without first receiving a message, it must use the number zero:

```
[0,{response}]
```

Then channel handler will then get `{response}` converted to Vim types. If the channel does not have a handler the message is dropped.

It is also possible to use `ch_sendraw()` and `ch_evalraw()` on a JSON or JS channel. The caller is then completely responsible for correct encoding and decoding.

5. Channel commands

channel-commands

With a JSON channel the process can send commands to Vim that will be handled by Vim internally, it does not require a handler for the channel.

Possible commands are:

E903 E904 E905

```
["redraw", {forced}]
["ex",      {Ex command}]
["normal", {Normal mode command}]
["expr",   {expression}, {number}]
["expr",   {expression}]
["call",   {func name}, {argument list}, {number}]
["call",   {func name}, {argument list}]
```

With all of these: Be careful what these commands do! You can easily interfere with what the user is doing. To avoid trouble use `mode()` to check that the editor is in the expected state. E.g., to send keys that must be inserted as text, not executed as a command:

```
["ex","if mode() == 'i' | call feedkeys('ClassName') | endif"]
```

Errors in these commands are normally not reported to avoid them messing up the display. If you do want to see them, set the `'verbose'` option to 3 or higher.

Command "redraw"

The other commands do not explicitly update the screen, so that you can send a sequence of commands without the cursor moving around. A redraw can happen as a side effect of some commands. You must end with the "redraw" command to show any changed text and show the cursor where it belongs.

The argument is normally an empty string:

```
["redraw", ""]
```

To first clear the screen pass "force":

```
["redraw", "force"]
```

Command "ex"

The "ex" command is executed as any Ex command. There is no response for completion or error. You could use functions in an `autoload` script:

```
["ex","call myscript#MyFunc(arg)"]
```

You can also use `"call feedkeys() "` to insert any key sequence.

When there is an error a message is written to the channel log, if it exists, and `v:errmsg` is set to the error.

Command "normal"

The "normal" command is executed like with `":normal!"`, commands are not mapped. Example to open the folds under the cursor:

```
["normal" "z0"]
```

Command "expr" with response

The "expr" command can be used to get the result of an expression. For example, to get the number of lines in the current buffer:

```
["expr","line('$')", -2]
```

It will send back the result of the expression:

```
[-2, "last line"]
```

The format is:

```
[{number}, {result}]
```

Here `{number}` is the same as what was in the request. Use a negative number to avoid confusion with message that Vim sends. Use a different number on every request to be able to match the request with the response.

`{result}` is the result of the evaluation and is JSON encoded. If the evaluation fails or the result can't be encoded in JSON it is the string "ERROR".

Command "expr" without a response

This command is similar to "expr" above, but does not send back any response. Example:

```
["expr","setline('$', ['one', 'two', 'three'])"]
```

There is no third argument in the request.

Command "call"

This is similar to "expr", but instead of passing the whole expression as a string this passes the name of a function and a list of arguments. This avoids the conversion of the arguments to a string and escaping and concatenating them. Example:

```
["call", "line", ["$"], -2]
```

Leave out the fourth argument if no response is to be sent:

```
["call", "setline", ["$"], ["one", "two", "three"]]
```

6. Using a RAW or NL channel

`channel-raw`

If mode is RAW or NL then a message can be sent like this:

```
let response = ch_evalraw(channel, {string})
```

The `{string}` is sent as-is. The response will be what can be read from the channel right away. Since Vim doesn't know how to recognize the end of the message you need to take care of it yourself. The timeout applies for reading the first byte, after that it will not wait for anything more.

If mode is "nl" you can send a message in a similar way. You are expected to put in the NL after each message. Thus you can also send several messages ending in a NL at once. The response will be the text up to and including the first NL. This can also be just the NL for an empty response. If no NL was read before the channel timeout an empty string is returned.

To send a message, without expecting a response:

```
call ch_sendraw(channel, {string})
```

The process can send back a response, the channel handler will be called with it.

`channel-onetime-callback`

To send a message and letting the response handled by a specific function, asynchronously:

```
call ch_sendraw(channel, {string}, {'callback': 'MyHandler'})
```

This `{string}` can also be JSON, use `json_encode()` to create it and `json_decode()` to handle a received JSON message.

It is not possible to use `ch_evaluate()` or `ch_sendexpr()` on a raw channel.

A String in Vim cannot contain NUL bytes. To send or receive NUL bytes read or write from a buffer. See `in_io-buffer` and `out_io-buffer`.

7. More channel functions

[channel-more](#)

To obtain the status of a channel: `ch_status(channel)`. The possible results are:

| | |
|------------|---|
| "fail" | Failed to open the channel. |
| "open" | The channel can be used. |
| "buffered" | The channel was closed but there is data to read. |
| "closed" | The channel was closed. |

To obtain the job associated with a channel: `ch_getjob(channel)`

To read one message from a channel:

```
let output = ch_read(channel)
```

This uses the channel timeout. To read without a timeout, just get any message that is available:

```
let output = ch_read(channel, {'timeout': 0})
```

When no message was available then the result is `v:none` for a JSON or JS mode channels, an empty string for a RAW or NL channel. You can use `ch_canread()` to check if there is something to read.

Note that when there is no callback, messages are dropped. To avoid that add a close callback to the channel.

To read all normal output from a RAW channel that is available:

```
let output = ch_readraw(channel)
```

To read all error output from a RAW channel that is available:

```
let output = ch_readraw(channel, {"part": "err"})
```

Note that if the channel is in NL mode, `ch_readraw()` will only return one line for each call.

`ch_read()` and `ch_readraw()` use the channel timeout. When there is nothing to read within that time an empty string is returned. To specify a different timeout in msec use the "timeout" option:

```
{"timeout": 123}
```

To read from the error output use the "part" option:

```
{"part": "err"}
```

To read a message with a specific ID, on a JS or JSON channel:

```
{"id": 99}
```

When no ID is specified or the ID is `-1`, the first message is returned. This overrules any callback waiting for this message.

For a RAW channel this returns whatever is available, since Vim does not know where a message ends.

For a NL channel this returns one message.

For a JS or JSON channel this returns one decoded message.
This includes any sequence number.

8. Channel functions details

[channel-functions-details](#)

`ch_canread({handle})` [ch_canread\(\)](#)
Return non-zero when there is something to read from `{handle}`.
`{handle}` can be a Channel or a Job that has a Channel.

This is useful to read from a channel at a convenient time,
e.g. from a timer.

Note that messages are dropped when the channel does not have
a callback. Add a close callback to avoid that.

Can also be used as a [method](#) :
`GetChannel()->ch_canread()`

Return type: [Number](#)

`ch_close({handle})` [ch_close\(\)](#)
Close `{handle}`. See [channel-close](#) .
`{handle}` can be a Channel or a Job that has a Channel.
A close callback is not invoked.

Can also be used as a [method](#) :
`GetChannel()->ch_close()`

Return type: [Number](#)

`ch_close_in({handle})` [ch_close_in\(\)](#)
Close the "in" part of `{handle}`. See [channel-close-in](#) .
`{handle}` can be a Channel or a Job that has a Channel.
A close callback is not invoked.

Can also be used as a [method](#) :
`GetChannel()->ch_close_in()`

Return type: [Number](#)

`ch_evaluate({handle}, {expr} [, {options}])` [ch_evaluate\(\)](#)
Send `{expr}` over `{handle}`. The `{expr}` is encoded
according to the type of channel. The function cannot be used
with a raw channel. See [channel-use](#) .
`{handle}` can be a Channel or a Job that has a Channel.
When using the "lsp" channel mode, `{expr}` must be a [Dict](#) .
[E917](#)
`{options}` must be a Dictionary. It must not have a "callback"
entry. It can have a "timeout" entry to specify the timeout
for this specific request.

`ch_evaluate()` waits for a response and returns the decoded

expression. When there is an error or timeout it returns an empty `String` or, when using the "lsp" channel mode, returns an empty `Dict` .

Note that while waiting for the response, Vim handles other messages. You need to make sure this doesn't cause trouble.

Can also be used as a `method` :
`GetChannel()->ch_evalexp(expr)`

Return type: `dict<any>` or `String`

`ch_evalraw({handle}, {string} [, {options}])` `ch_evalraw()`

Send `{string}` over `{handle}`.
`{handle}` can be a Channel or a Job that has a Channel.

Works like `ch_evalexp()` , but does not encode the request or decode the response. The caller is responsible for the correct contents. Also does not add a newline for a channel in NL mode, the caller must do that. The NL in the response is removed.

Note that Vim does not know when the text received on a raw channel is complete, it may only return the first part and you need to use `ch_readraw()` to fetch the rest.
See `channel-use` .

Can also be used as a `method` :
`GetChannel()->ch_evalraw(rawstring)`

Return type: `dict<any>` or `String`

`ch_getbufnr({handle}, {what})` `ch_getbufnr()`

Get the buffer number that `{handle}` is using for String `{what}`.
`{handle}` can be a Channel or a Job that has a Channel.
`{what}` can be "err" for stderr, "out" for stdout or empty for socket output.
Returns -1 when there is no buffer.

Can also be used as a `method` :
`GetChannel()->ch_getbufnr(what)`

Return type: `Number`

`ch_getjob({channel})` `ch_getjob()`

Get the Job associated with `{channel}`.
If there is no job calling `job_status()` on the returned Job will result in "fail".

Can also be used as a `method` :
`GetChannel()->ch_getjob()`

Return type: `job` or `String`

`ch_info({handle})` `ch_info()`
Returns a Dictionary with information about `{handle}`. The items are:

"id" number of the channel
"status" "open", "buffered" or "closed", like `ch_status()`

When opened with `ch_open()`:

"hostname" the hostname of the address
"port" the port of the address
"path" the path of the Unix-domain socket
"sock_status" "open" or "closed"
"sock_mode" "NL", "RAW", "JSON" or "JS"
"sock_io" "socket"
"sock_timeout" timeout in msec

Note that "path" is only present for Unix-domain sockets, for regular ones "hostname" and "port" are present instead.

When opened with `job_start()`:

"out_status" "open", "buffered" or "closed"
"out_mode" "NL", "RAW", "JSON" or "JS"
"out_io" "null", "pipe", "file" or "buffer"
"out_timeout" timeout in msec
"err_status" "open", "buffered" or "closed"
"err_mode" "NL", "RAW", "JSON" or "JS"
"err_io" "out", "null", "pipe", "file" or "buffer"
"err_timeout" timeout in msec
"in_status" "open" or "closed"
"in_mode" "NL", "RAW", "JSON", "JS" or "LSP"
"in_io" "null", "pipe", "file" or "buffer"
"in_timeout" timeout in msec

Can also be used as a **method** :
`GetChannel()->ch_info()`

Return type: dict<any>

`ch_log({msg} [, {handle}])` `ch_log()`

Write String `{msg}` in the channel log file, if it was opened with `ch_logfile()`.

The text "ch_log():" is prepended to the message to make clear it came from this function call and make it easier to find in the log file.

When `{handle}` is passed the channel number is used for the message.

`{handle}` can be a Channel or a Job that has a Channel. The Channel must be open for the channel number to be used.

Can also be used as a **method** :
`'did something'->ch_log()`

Return type: dict<any>

`ch_logfile({fname} [, {mode}])` `ch_logfile()`

Start logging channel activity to `{fname}`.
When `{fname}` is an empty string: stop logging.

When `{mode}` is omitted or contains "a" or is "o" then append to the file.
When `{mode}` contains "w" and not "a" start with an empty file.
When `{mode}` contains "o" then log all terminal output.
Otherwise only some interesting terminal output is logged.

Use `ch_log()` to write log messages. The file is flushed after every message, on Unix you can use "tail -f" to see what is going on in real time.

To enable the log very early, to see what is received from a terminal during startup, use `--log` (this uses mode "ao"):
`vim --log logfile`

This function is not available in the `sandbox` .
NOTE: the channel communication is stored in the file, be aware that this may contain confidential and privacy sensitive information, e.g. a password you type in a terminal window.

Can also be used as a `method` :
`'logfile'->ch_logfile('w')`

Return type: `Number`

`ch_open({address} [, {options}])` `ch_open()`

Open a channel to `{address}`. See `channel` .
Returns a Channel. Use `ch_status()` to check for failure.

`{address}` is a String, see `channel-address` for the possible accepted forms.

If `{options}` is given it must be a `Dictionary` .
See `channel-open-options` .

Can also be used as a `method` :
`GetAddress()->ch_open()`

Return type: `channel`

`ch_read({handle} [, {options}])` `ch_read()`

Read from `{handle}` and return the received message.
`{handle}` can be a Channel or a Job that has a Channel.
For a NL channel this waits for a NL to arrive, except when there is nothing more to read (channel was closed).
See `channel-more` .

Can also be used as a `method` :
`GetChannel()->ch_read()`

Return type: `String`

`ch_readblob({handle} [, {options}])` `ch_readblob()`
Like `ch_read()` but reads binary data and returns a `Blob` .
See `channel-more` .

Can also be used as a `method` :
`GetChannel()->ch_readblob()`

Return type: `Blob`

`ch_readdraw({handle} [, {options}])` `ch_readdraw()`
Like `ch_read()` but for a JS and JSON channel does not decode the message. For a NL channel it does not block waiting for the NL to arrive, but otherwise works like `ch_read()`.
See `channel-more` .

Can also be used as a `method` :
`GetChannel()->ch_readdraw()`

Return type: `String`

`ch_sendexpr({handle}, {expr} [, {options}])` `ch_sendexpr()`
Send `{expr}` over `{handle}`. The `{expr}` is encoded according to the type of channel. The function cannot be used with a raw channel.

See `channel-use` . `E912`
`{handle}` can be a Channel or a Job that has a Channel.
When using the "lsp" channel mode, `{expr}` must be a `Dict` .

If the channel mode is "lsp", then returns a Dict. Otherwise returns an empty String. If the "callback" item is present in `{options}`, then the returned Dict contains the ID of the request message. The ID can be used to send a cancellation request to the LSP server (if needed). Returns an empty Dict on error.

If a response message is not expected for `{expr}`, then don't specify the "callback" item in `{options}`.

Can also be used as a `method` :
`GetChannel()->ch_sendexpr(expr)`

Return type: `dict<any>` or `String`

`ch_senddraw({handle}, {expr} [, {options}])` `ch_senddraw()`
Send `String` or `Blob` `{expr}` over `{handle}`.
Works like `ch_sendexpr()` , but does not encode the request or decode the response. The caller is responsible for the correct contents. Also does not add a newline for a channel in NL mode, the caller must do that. The NL in the response is removed.

See `channel-use` .

Can also be used as a `method` :

`GetChannel()->ch_sendraw(rawexpr)`

Return type: `dict<any>` or `String`

`ch_setoptoptions({handle}, {options})` `ch_setoptoptions()`

Set options on `{handle}`:

| | |
|-------------------------|------------------------------|
| <code>"callback"</code> | the channel callback |
| <code>"timeout"</code> | default read timeout in msec |
| <code>"mode"</code> | mode for the whole channel |

See `ch_open()` for more explanation.

`{handle}` can be a Channel or a Job that has a Channel.

Note that changing the mode may cause queued messages to be lost.

These options cannot be changed:

| | |
|-------------------------|--|
| <code>"waittime"</code> | only applies to <code>ch_open()</code> |
|-------------------------|--|

Can also be used as a `method` :

`GetChannel()->ch_setoptoptions(options)`

Return type: `Number`

`ch_status({handle} [, {options}])` `ch_status()`

Return the status of `{handle}`:

| | |
|-------------------------|-------------------------------------|
| <code>"fail"</code> | failed to open the channel |
| <code>"open"</code> | channel can be used |
| <code>"buffered"</code> | channel can be read, not written to |
| <code>"closed"</code> | channel can not be used |

`{handle}` can be a Channel or a Job that has a Channel.

"buffered" is used when the channel was closed but there is still data that can be obtained with `ch_read()` .

If `{options}` is given it can contain a "part" entry to specify the part of the channel to return the status for: "out" or "err". For example, to get the error status:

`ch_status(job, {"part": "err"})`

Can also be used as a `method` :

`GetChannel()->ch_status()`

Return type: `String`

=====

9. Starting a job with a channel `job-start` `job`

To start a job and open a channel for stdin/stdout/stderr:

`let job = job_start(command, {options})`

You can get the channel with:

`let channel = job_getchannel(job)`

The channel will use NL mode. If you want another mode it's best to specify this in `{options}`. When changing the mode later some text may have already

been received and not parsed correctly.

If the command produces a line of output that you want to deal with, specify a handler for stdout:

```
let job = job_start(command, {"out_cb": "MyHandler"})
```

The function will be called with the channel and a message. You would define it like this:

```
func MyHandler(channel, msg)
```

Without the handler you need to read the output with `ch_read()` or `ch_readraw()`. You can do this in the close callback, see [read-in-close-cb](#).

Note that if the job exits before you read the output, the output may be lost. This depends on the system (on Unix this happens because closing the write end of a pipe causes the read end to get EOF). To avoid this make the job sleep for a short while before it exits.

The handler defined for "out_cb" will not receive stderr. If you want to handle that separately, add an "err_cb" handler:

```
let job = job_start(command, {"out_cb": "MyHandler",  
 \ "err_cb": "ErrHandler"})
```

If you want to handle both stderr and stdout with one handler use the "callback" option:

```
let job = job_start(command, {"callback": "MyHandler"})
```

Depending on the system, starting a job can put Vim in the background, the started job gets the focus. To avoid that, use the ``foreground()`` function. This might not always work when called early, put in the callback handler or use a timer to call it after the job has started.

You can send a message to the command with `ch_evalraw()`. If the channel is in JSON or JS mode you can use `ch_evalexpr()`.

There are several options you can use, see [job-options](#).

For example, to start a job and write its output in buffer "dummy":

```
let logjob = job_start("tail -f /tmp/log",  
 \ {'out_io': 'buffer', 'out_name': 'dummy'})  
sbuf dummy
```

Job input from a buffer

[in_io-buffer](#)

To run a job that reads from a buffer:

```
let job = job_start({command},  
 \ {'in_io': 'buffer', 'in_name': 'mybuffer'})
```

[E915](#) [E918](#)

The buffer is found by name, similar to `bufnr()`. The buffer must exist and be loaded when `job_start()` is called.

By default this reads the whole buffer. This can be changed with the "in_top" and "in_bot" options.

A special mode is when "in_top" is set to zero and "in_bot" is not set: Every time a line is added to the buffer, the last-but-one line will be sent to the job stdin. This allows for editing the last line and sending it when pressing Enter.

[channel-close-in](#)

When not using the special mode the pipe or socket will be closed after the last line has been written. This signals the reading end that the input finished. You can also use [ch_close_in\(\)](#) to close it sooner.

NUL bytes in the text will be passed to the job (internally Vim stores these as NL bytes).

Reading job output in the close callback

[read-in-close-cb](#)

If the job can take some time and you don't need intermediate results, you can add a close callback and read the output there:

```
func! CloseHandler(channel)
  while ch_status(a:channel, {'part': 'out'}) == 'buffered'
    echomsg ch_read(a:channel)
  endwhile
endfunc
let job = job_start(command, {'close_cb': 'CloseHandler'})
```

You will want to do something more useful than "echomsg".

10. Starting a job without a channel

[job-start-nochannel](#)

To start another process without creating a channel:

```
let job = job_start(command,
  \ {"in_io": "null", "out_io": "null", "err_io": "null"})
```

This starts {command} in the background, Vim does not wait for it to finish.

When Vim sees that neither stdin, stdout or stderr are connected, no channel will be created. Often you will want to include redirection in the command to avoid it getting stuck.

There are several options you can use, see [job-options](#) .

[job-start-if-needed](#)

To start a job only when connecting to an address does not work, do something like this:

```
let channel = ch_open(address, {"waittime": 0})
if ch_status(channel) == "fail"
  let job = job_start(command)
  let channel = ch_open(address, {"waittime": 1000})
endif
```

Note that the waittime for ch_open() gives the job one second to make the port available.

11. Job functions

[job-functions-details](#)

`job_getchannel({job})`

[job_getchannel\(\)](#)

Get the channel handle that `{job}` is using.

To check if the job has no channel:

```
if string(job_getchannel(job)) == 'channel fail'
```

Can also be used as a [method](#) :

```
GetJob()->job_getchannel()
```

Return type: [channel](#)

`job_info([{{job}}])`

[job_info\(\)](#)

Returns a Dictionary with information about `{job}`:

```
"status"      what job\_status\(\) returns
"channel"     what job\_getchannel\(\) returns
"cmd"        List of command arguments used to start the job
"process"    process ID
"tty_in"     terminal input name, empty when none
"tty_out"    terminal output name, empty when none
"exitval"    only valid when "status" is "dead"
"exit_cb"    function to be called on exit
"stoponexit" job-stoponexit
```

Only in Unix:

```
"termsig"    the signal which terminated the process
              (See job\_stop\(\) for the values)
              only valid when "status" is "dead"
```

Only in MS-Windows:

```
"tty_type"   Type of virtual console in use.
              Values are "winpty" or "conpty".
              See 'termwintype'.
```

Without any arguments, returns a List with all Job objects.

Can also be used as a [method](#) :

```
GetJob()->job_info()
```

Return type: `dict<any>` or `list<job>` depending on whether `{job}` was given

`job_setoptions({job}, {options})`

[job_setoptions\(\)](#)

Change options for `{job}`. Supported are:

```
"stoponexit" job-stoponexit
"exit_cb"    job-exit\_cb
```

Can also be used as a [method](#) :

```
GetJob()->job_setoptions(options)
```

Return type: [Number](#)

`job_start({command} [, {options}])` `job_start()`
Start a job and return a Job object. Unlike `system()` and `!cmd` this does not wait for the job to finish. To start a job in a terminal window see `term_start()` .

If the job fails to start then `job_status()` on the returned Job object results in "fail" and none of the callbacks will be invoked.

`{command}` can be a String. This works best on MS-Windows. On Unix it is split up in white space separated parts to be passed to `execvp()`. Arguments in double quotes can contain white space.

`{command}` can be a List, where the first item is the executable and further items are the arguments. All items are converted to String. This works best on Unix.

On MS-Windows, `job_start()` makes a GUI application hidden. If you want to show it, use `!start` instead.

The command is executed directly, not through a shell, the `'shell'` option is not used. To use the shell:

```
let job = job_start(["/bin/sh", "-c", "echo hello"])
```

Or:

```
let job = job_start('/bin/sh -c "echo hello"')
```

Note that this will start two processes, the shell and the command it executes. If you don't want this use the "exec" shell command.

On Unix `$PATH` is used to search for the executable only when the command does not contain a slash.

The job will use the same terminal as Vim. If it reads from stdin the job and Vim will be fighting over input, that doesn't work. Redirect stdin and stdout to avoid problems:

```
let job = job_start(['sh', '-c', "myserver </dev/null >/dev/null"])
```

The returned Job object can be used to get the status with `job_status()` and stop the job with `job_stop()` .

Note that the job object will be deleted if there are no references to it. This closes the stdin and stderr, which may cause the job to fail with an error. To avoid this keep a reference to the job. Thus instead of:

```
call job_start('my-command')
```

use:

```
let myjob = job_start('my-command')
```

and `unlet "myjob"` once the job is not needed or is past the point where it would fail (e.g. when it prints a message on startup). Keep in mind that variables local to a function will cease to exist if the function returns. Use a script-local variable if needed:

```
let s:myjob = job_start('my-command')
```

`{options}` must be a Dictionary. It can contain many optional items, see [job-options](#) .

Can also be used as a [method](#) :
`BuildCommand()->job_start()`

Return type: [job](#)

`job_status({job})` [job_status\(\)](#) E916

Returns a String with the status of `{job}`:

```
"run"   job is running
"fail"  job failed to start
"dead"  job died or was stopped after running
```

On Unix a non-existing command results in "dead" instead of "fail", because a fork happens before the failure can be detected.

If in Vim9 script a variable is declared with type "job" but never assigned to, passing that variable to `job_status()` returns "fail".

If an exit callback was set with the "exit_cb" option and the job is now detected to be "dead" the callback will be invoked.

For more information see [job_info\(\)](#) .

Can also be used as a [method](#) :
`GetJob()->job_status()`

Return type: [String](#)

`job_stop({job} [, {how}])` [job_stop\(\)](#)

Stop the `{job}`. This can also be used to signal the job.

When `{how}` is omitted or is "term" the job will be terminated. For Unix SIGTERM is sent. On MS-Windows the job will be terminated forcibly (there is no "gentle" way). This goes to the process group, thus children may also be affected.

Effect for Unix:

```
"term"  SIGTERM (default)
"hup"   SIGHUP
"quit"  SIGQUIT
"int"   SIGINT
"kill"  SIGKILL (strongest way to stop)
number  signal with that number
```

Effect for MS-Windows:

```

"term"    terminate process forcedly (default)
"hup"     CTRL_BREAK
"quit"    CTRL_BREAK
"int"     CTRL_C
"kill"    terminate process forcedly
Others    CTRL_BREAK

```

On Unix the signal is sent to the process group. This means that when the job is "sh -c command" it affects both the shell and the command.

The result is a Number: 1 if the operation could be executed, 0 if "how" is not supported on the system.

Note that even when the operation was executed, whether the job was actually stopped needs to be checked with `job_status()` .

If the status of the job is "dead", the signal will not be sent. This is to avoid to stop the wrong job (esp. on Unix, where process numbers are recycled).

When using "kill" Vim will assume the job will die and close the channel.

Can also be used as a `method` :
`GetJob()->job_stop()`

Return type: `Number`

12. Job options

job-options

The `{options}` argument in `job_start()` is a dictionary. All entries are optional. Some options can be used after the job has started, using `job_setoptions(job, {options})`. Many options can be used with the channel related to the job, using `ch_setoptions(channel, {options})`. See `job_setoptions()` and `ch_setoptions()` .

```

"mode"          mode specifically for stdin, only when using pipes
"out_mode"      mode specifically for stdout, only when using pipes
"err_mode"      mode specifically for stderr, only when using pipes
See channel-mode for the values.

```

Note: when setting "mode" the part specific mode is overwritten. Therefore set "mode" first and the part specific mode later.

Note: when writing to a file or buffer and when reading from a buffer NL mode is used by default.

```

"noblock": 1    When writing use a non-blocking write call. This

```

avoids getting stuck if Vim should handle other messages in between, e.g. when a job sends back data to Vim. It implies that when `ch_sendraw()` returns not all data may have been written yet.

This option was added in patch 8.1.0350, test with:

```
if has("patch-8.1.350")
  let options['noblock'] = 1
endif
```

| | |
|------------------------|--|
| | job-callback |
| "callback": handler | Callback for something to read on any part of the channel. |
| | job-out_cb out_cb |
| "out_cb": handler | Callback for when there is something to read on stdout. Only for when the channel uses pipes. When "out_cb" wasn't set the channel callback is used. The two arguments are the channel and the message. |
| | job-err_cb err_cb |
| "err_cb": handler | Callback for when there is something to read on stderr. Only for when the channel uses pipes. When "err_cb" wasn't set the channel callback is used. The two arguments are the channel and the message. |
| | job-close_cb |
| "close_cb": handler | Callback for when the channel is closed. Same as "close_cb" on ch_open() , see close_cb . |
| | job-drop |
| "drop": when | Specifies when to drop messages. Same as "drop" on ch_open() , see channel-drop . For "auto" the exit_cb is not considered. |
| | job-exit_cb |
| "exit_cb": handler | Callback for when the job ends. The arguments are the job and the exit status.
Vim checks up to 10 times per second for jobs that ended. The check can also be triggered by calling job_status() , which may then invoke the exit_cb handler.
Note that data can be buffered, callbacks may still be called after the process ends. |
| | job-timeout |
| "timeout": time | The time to wait for a request when blocking, E.g. when using ch_evalexp() . In milliseconds. The default is 2000 (2 seconds). |
| | out_timeout err_timeout |
| "out_timeout": time | Timeout for stdout. Only when using pipes. |
| "err_timeout": time | Timeout for stderr. Only when using pipes.
Note: when setting "timeout" the part specific mode is overwritten. Therefore set "timeout" first and the part specific mode later. |
| | job-stoponexit |
| "stoponexit": {signal} | Send {signal} to the job when Vim exits. See job_stop() for possible values. |
| "stoponexit": "" | Do not stop the job when Vim exits. |

The default is "term".

| | |
|--------------------------|--|
| | job-term |
| "term": "open" | Start a terminal in a new window and connect the job stdin/stdout/stderr to it. Similar to using <code>:terminal`</code> .
NOTE: Not implemented yet! |
| "channel": {channel} | Use an existing channel instead of creating a new one. The parts of the channel that get used for the new job will be disconnected from what they were used before. If the channel was still used by another job this may cause I/O errors.
Existing callbacks and other settings remain. |
| "pty": 1 | Use a pty (pseudo-tty) instead of a pipe when possible. This is most useful in combination with a terminal window, see terminal .
{only on Unix and Unix-like systems} |
| | job-in_io in_top in_bot in_name in_buf |
| "in_io": "null" | disconnect stdin (read from /dev/null) |
| "in_io": "pipe" | stdin is connected to the channel (default) |
| "in_io": "file" | stdin reads from a file |
| "in_io": "buffer" | stdin reads from a buffer |
| "in_top": number | when using "buffer": first line to send (default: 1) |
| "in_bot": number | when using "buffer": last line to send (default: last) |
| "in_name": "/path/file" | the name of the file or buffer to read from |
| "in_buf": number | the number of the buffer to read from |
| | job-out_io out_name out_buf |
| "out_io": "null" | disconnect stdout (goes to /dev/null) |
| "out_io": "pipe" | stdout is connected to the channel (default) |
| "out_io": "file" | stdout writes to a file |
| "out_io": "buffer" | stdout appends to a buffer (see below) |
| "out_name": "/path/file" | the name of the file or buffer to write to |
| "out_buf": number | the number of the buffer to write to |
| "out_modifiable": 0 | when writing to a buffer, 'modifiable' will be off (see below) |
| "out_msg": 0 | when writing to a new buffer, the first line will be set to "Reading from channel output..." |
| | job-err_io err_name err_buf |
| "err_io": "out" | stderr messages to go to stdout |
| "err_io": "null" | disconnect stderr (goes to /dev/null) |
| "err_io": "pipe" | stderr is connected to the channel (default) |
| "err_io": "file" | stderr writes to a file |
| "err_io": "buffer" | stderr appends to a buffer (see below) |
| "err_name": "/path/file" | the name of the file or buffer to write to |
| "err_buf": number | the number of the buffer to write to |
| "err_modifiable": 0 | when writing to a buffer, 'modifiable' will be off (see below) |
| "err_msg": 0 | when writing to a new buffer, the first line will be set to "Reading from channel error..." |

"block_write": number only for testing: pretend every other write to stdin will block

"env": dict environment variables for the new process

"cwd": "/path/to/dir" current working directory for the new process;
if the directory does not exist an error is given

Writing to a buffer

out_io-buffer

When the out_io or err_io mode is "buffer" and there is a callback, the text is appended to the buffer before invoking the callback.

When a buffer is used both for input and output, the output lines are put above the last line, since the last line is what is written to the channel input. Otherwise lines are appended below the last line.

When using JS or JSON mode with "buffer", only messages with zero or negative ID will be added to the buffer, after decoding + encoding. Messages with a positive number will be handled by a callback, commands are handled as usual.

The name of the buffer from "out_name" or "err_name" is compared the full name of existing buffers, also after expanding the name for the current directory. E.g., when a buffer was created with ":edit somename" and the buffer name is "somename" it will use that buffer.

If there is no matching buffer a new buffer is created. Use an empty name to always create a new buffer. `ch_getbufnr()` can then be used to get the buffer number.

For a new buffer '**buftype**' is set to "nofile" and '**bufhidden**' to "hide". If you prefer other settings, create the buffer first and pass the buffer number.

out_modifiable err_modifiable

The "out_modifiable" and "err_modifiable" options can be used to set the '**modifiable**' option off, or write to a buffer that has '**modifiable**' off. That means that lines will be appended to the buffer, but the user can't easily change the buffer.

out_msg err_msg

The "out_msg" option can be used to specify whether a new buffer will have the first line set to "Reading from channel output...". The default is to add the message. "err_msg" does the same for channel error.

When an existing buffer is to be written where '**modifiable**' is off and the "out_modifiable" or "err_modifiable" options is not zero, an error is given and the buffer will not be written to.

When the buffer written to is displayed in a window and the cursor is in the first column of the last line, the cursor will be moved to the newly added line and the window is scrolled up to show the cursor if needed.

Undo is synced for every added line. NUL bytes are accepted (internally Vim stores these as NL bytes).

Writing to a file

E920

The file is created with permissions 600 (read-write for the user, not accessible for others). Use `setfperm()` to change this.

If the file already exists it is truncated.

13. Controlling a job

job-control

To get the status of a job:

```
echo job_status(job)
```

To make a job stop running:

```
job_stop(job)
```

This is the normal way to end a job. On Unix it sends a SIGTERM to the job. It is possible to use other ways to stop the job, or even send arbitrary signals. E.g. to force a job to stop, "kill it":

```
job_stop(job, "kill")
```

For more options see `job_stop()` .

14. Using a prompt buffer

prompt-buffer

If you want to type input for the job in a Vim window you have a few options:

- Use a normal buffer and handle all possible commands yourself. This will be complicated, since there are so many possible commands.
- Use a terminal window. This works well if what you type goes directly to the job and the job output is directly displayed in the window. See `terminal-window` .
- Use a window with a prompt buffer. This works well when entering a line for the job in Vim while displaying (possibly filtered) output from the job.

A prompt buffer is created by setting `'buftype'` to "prompt". You would normally only do that in a newly created buffer.

The user can edit and enter one line of text at the very last line of the buffer. When pressing Enter in the prompt line the callback set with `prompt_setcallback()` is invoked. It would normally send the line to a job. Another callback would receive the output from the job and display it in the buffer, below the prompt (and above the next prompt).

Only the text in the last line, after the prompt, is editable. The rest of the buffer is not modifiable with Normal mode commands. It can be modified by calling functions, such as `append()` . Using other commands may mess up the buffer.

After setting `'buftype'` to "prompt" Vim does not automatically start Insert mode, use `':startinsert'` if you want to enter Insert mode, so that the user can start typing a line.

The text of the prompt can be set with the `prompt_setprompt()` function. If no prompt is set with `prompt_setprompt()`, `"% "` is used. You can get the effective prompt text for a buffer, with `prompt_getprompt()`.

The user can go to Normal mode and navigate through the buffer. This can be useful to see older output or copy text.

The **CTRL-W** key can be used to start a window command, such as **CTRL-W w** to switch to the next window. This also works in Insert mode (use Shift-CTRL-W to delete a word). When leaving the window Insert mode will be stopped. When coming back to the prompt window Insert mode will be restored.

Any command that starts Insert mode, such as "a", "i", "A" and "I", will move the cursor to the last line. "A" will move to the end of the line, "I" to the start of the line.

Here is an example for Unix. It starts a shell in the background and prompts for the next shell command. Output from the shell is displayed above the prompt.

```
" Create a channel log so we can see what happens.
call ch_logfile('logfile', 'w')

" Function handling a line of text that has been typed.
func TextEntered(text)
  " Send the text to a shell with Enter appended.
  call ch_sendraw(g:shell_job, a:text .. "\n")
endfunc

" Function handling output from the shell: Add it above the prompt.
func GotOutput(channel, msg)
  call append(line("$") - 1, "- " .. a:msg)
endfunc

" Function handling the shell exits: close the window.
func JobExit(job, status)
  quit!
endfunc

" Start a shell in the background.
let shell_job = job_start(["/bin/sh"], #{
  \ out_cb: function('GotOutput'),
  \ err_cb: function('GotOutput'),
  \ exit_cb: function('JobExit'),
  \ })

new
set buftype=prompt
let buf = bufnr('')
call prompt_setcallback(buf, function("TextEntered"))
eval prompt_setprompt(buf, "shell command: ")

" start accepting shell commands
startinsert
```

The same in Vim9 script:

```
vim9script

# Create a channel log so we can see what happens.
ch_logfile('logfile', 'w')

var shell_job: job

# Function handling a line of text that has been typed.
def TextEntered(text: string)
    # Send the text to a shell with Enter appended.
    ch_sendraw(shell_job, text .. "\n")
enddef

# Function handling output from the shell: Add it above the prompt.
def GotOutput(channel: channel, msg: string)
    append(line("$") - 1, "- " .. msg)
enddef

# Function handling the shell exits: close the window.
def JobExit(job: job, status: number)
    quit!
enddef

# Start a shell in the background.
shell_job = job_start(["/bin/sh"], {
    out_cb: GotOutput,
    err_cb: GotOutput,
    exit_cb: JobExit,
})

new
set buftype=prompt
var buf = bufnr('')
prompt_setcallback(buf, TextEntered)
prompt_setprompt(buf, "shell command: ")

# start accepting shell commands
startinsert
```

15. Language Server Protocol

[language-server-protocol](#)

The language server protocol specification is available at:

<https://microsoft.github.io/language-server-protocol/specification>

Each LSP protocol message starts with a simple HTTP header followed by the payload encoded in JSON-RPC format. This is described in:

<https://www.jsonrpc.org/specification>

To encode and send a LSP request/notification message in a Vim `Dict` into a LSP JSON-RPC message and to receive and decode a LSP JSON-RPC response/notification message into a Vim `Dict`, connect to the LSP server with the `channel-mode` set to "lsp".

For messages received on a channel with `channel-mode` set to "lsp", Vim will process the HTTP header and decode the JSON-RPC payload into a Vim `Dict` type and call the `channel-callback` function or the specified `channel-onetime-callback` function. When sending messages on a channel using the `ch_evalexpr()` or `ch_sendexpr()` functions, Vim will add the HTTP header and encode the Vim expression into JSON. Refer to `json_encode()` and `json_decode()` for more information about how Vim encodes and decodes the builtin types into JSON.

To open a channel using the 'lsp' mode, set the 'mode' item in the `ch_open()` `{options}` argument to 'lsp'. Example:

```
let ch = ch_open(..., #{mode: 'lsp'})
```

To open a channel using the 'lsp' mode with a job, set the 'in_mode' and 'out_mode' items in the `job_start()` `{options}` argument to 'lsp'. Example:

```
let cmd = ['clangd', '--background-index', '--clang-tidy']
let opts = {}
let opts.in_mode = 'lsp'
let opts.out_mode = 'lsp'
let opts.err_mode = 'nl'
let opts.out_cb = function('LspOutCallback')
let opts.err_cb = function('LspErrCallback')
let opts.exit_cb = function('LspExitCallback')
let job = job_start(cmd, opts)
```

Note that if a job outputs LSP messages on stdout and non-LSP messages on stderr, then the channel-callback function should handle both the message formats appropriately or you should use a separate callback function for "out_cb" and "err_cb" to handle them as shown above.

To synchronously send a JSON-RPC request to the server, use the `ch_evalexpr()` function. This function will wait and return the decoded response message from the server. You can use either the `channel-timeout` or the 'timeout' field in the `{options}` argument to control the response wait time. If the request times out, then an empty `Dict` is returned. Example:

```
let req = {}
let req.method = 'textDocument/definition'
let req.params = {}
let req.params.textDocument = #{uri: 'a.c'}
let req.params.position = #{line: 10, character: 3}
let defs = ch_evalexpr(ch, req, #{timeout: 100})
if defs->empty()
    ... <handle failure>
endif
```

Note that in the request message the 'id' field should not be specified. If it

is specified, then Vim will overwrite the value with an internally generated identifier. Vim currently supports only a number type for the `'id'` field. The callback function will be invoked for both a successful and a failed RPC request.

To send a JSON-RPC request to the server and asynchronously process the response, use the `ch_sendexpr()` function and supply a callback function. If the `"id"` field is present in the request message, then Vim will overwrite it with an internally generated number. This function returns a Dict with the identifier used for the message. This can be used to send cancellation request to the LSP server (if needed). Example:

```
let req = {}
let req.method = 'textDocument/hover'
let req.id = 200
let req.params = {}
let req.params.textDocument = #{uri: 'a.c'}
let req.params.position = #{line: 10, character: 3}
let resp = ch_sendexpr(ch, req, #{callback: 'HoverFunc'})
```

To cancel an outstanding asynchronous LSP request sent to the server using the `ch_sendexpr()` function, send a cancellation message to the server using the `ch_sendexpr()` function with the ID returned by the `ch_sendexpr()` function for the request. Example:

```
" send a completion request
let req = {}
let req.method = 'textDocument/completion'
let req.params = {}
let req.params.textDocument = #{uri: 'a.c'}
let req.params.position = #{line: 10, character: 3}
let reqstatus = ch_sendexpr(ch, req, #{callback: 'LspComplete'})
" send a cancellation notification
let notif = {}
let notif.method = '$/cancelRequest'
let notif.id = reqstatus.id
call ch_sendexpr(ch, notif)
```

To send a JSON-RPC notification message to the server, use the `ch_sendexpr()` function. As the server will not send a response message to the notification, don't specify the `"callback"` item. Example:

```
call ch_sendexpr(ch, #{method: 'initialized'})
```

To respond to a JSON-RPC request message from the server, use the `ch_sendexpr()` function. In the response message, copy the `'id'` field value from the server request message. Example:

```
let resp = {}
let resp.id = req.id
let resp.result = 1
call ch_sendexpr(ch, resp)
```

The JSON-RPC notification messages from the server are delivered through the

`channel-callback` function.

Depending on the use case, you can use the `ch_evaluate()`, `ch_sendexpr()` and `ch_sendraw()` functions on the same channel.

A LSP request message has the following format (expressed as a Vim Dict). The "params" field is optional:

```
{
  "jsonrpc": "2.0",
  "id": <number>,
  "method": <string>,
  "params": <list|dict>
}
```

A LSP response message has the following format (expressed as a Vim Dict). The "result" and "error" fields are optional:

```
{
  "jsonrpc": "2.0",
  "id": <number>,
  "result": <vim type>
  "error": <dict>
}
```

A LSP notification message has the following format (expressed as a Vim Dict). The "params" field is optional:

```
{
  "jsonrpc": "2.0",
  "method": <string>,
  "params": <list|dict>
}
```

Folding

Folding folding folds

You can find an introduction on folding in chapter 28 of the user manual.
[usr_28.txt](#)

1. Fold methods [fold-methods](#)
2. Fold commands [fold-commands](#)
3. Fold options [fold-options](#)
4. Behavior of folds [fold-behavior](#)

{not available when compiled without the |+folding| feature}

=====

1. Fold methods

[fold-methods](#)

The folding method can be set with the **'foldmethod'** option.

When setting **'foldmethod'** to a value other than "manual", all folds are deleted and new ones created. Switching to the "manual" method doesn't remove the existing folds. This can be used to first define the folds automatically and then change them manually.

There are six methods to select folds:

| | |
|--------|---------------------------------------|
| manual | manually define folds |
| indent | more indent means a higher fold level |
| expr | specify an expression to define folds |
| syntax | folds defined by syntax highlighting |
| diff | folds for unchanged text |
| marker | folds defined by markers in the text |

MANUAL[fold-manual](#)

Use commands to manually define the fold regions. This can also be used by a script that parses text to find folds.

The level of a fold is only defined by its nesting. To increase the fold level of a fold for a range of lines, define a fold inside it that has the same lines.

The manual folds are lost when you abandon the file. To save the folds use the **:mkview** command. The view can be restored later with **:loadview** .

INDENT[fold-indent](#)

The folds are automatically defined by the indent of the lines.

The `foldlevel` is computed from the indent of the line, divided by the `'shiftwidth'` (rounded down). A sequence of lines with the same or higher fold level form a fold, with the lines with a higher level forming a nested fold.

The nesting of folds is limited with `'foldnestmax'`.

Some lines are ignored and get the fold level of the line above or below it, whichever is lower. These are empty or white lines and lines starting with a character in `'foldignore'`. White space is skipped before checking for characters in `'foldignore'`. For C use `"#"` to ignore preprocessor lines.

When you want to ignore lines in another way, use the `"expr"` method. The `indent()` function can be used in `'foldexpr'` to get the indent of a line.

EXPR

fold-expr

The folds are automatically defined by their `foldlevel`, like with the `"indent"` method. The value of the `'foldexpr'` option is evaluated to get the `foldlevel` of a line. Examples:

This will create a fold for all consecutive lines that start with a tab:

```
:set foldexpr=getline(v:lnum)[0]=="\t"
```

This will make a fold out of paragraphs separated by blank lines:

```
:set foldexpr=getline(v:lnum) =~ '\s*$' && getline(v:lnum+1) =~ '\S?' <1' :1
```

This does the same:

```
:set foldexpr=getline(v:lnum-1) =~ '\s*$' && getline(v:lnum) =~ '\S?' >1' :1
```

Note that backslashes must be used to escape characters that `:"set"` handles differently (space, backslash, double quote, etc., see [option-backslash](#)).

The most efficient is to call a compiled function without arguments:

```
:set foldexpr=MyFoldLevel()
```

The function must use `v:lnum`. See [expr-option-function](#).

These are the conditions with which the expression is evaluated:

- The current buffer and window are set for the line.
- The variable `"v:lnum"` is set to the line number.

The result of `foldexpr` then determines the fold level as follows:

| value | meaning |
|----------------|---|
| 0 | the line is not in a fold |
| 1, 2, .. | the line is in a fold with this level |
| -1 | the fold level is undefined, use the fold level of a line before or after this line, whichever is the lowest. |
| "=" | use fold level from the previous line |
| "a1", "a2", .. | add one, two, .. to the fold level of the previous line, use the result for the current line |
| "s1", "s2", .. | subtract one, two, .. from the fold level of the previous line, use the result for the next line |
| "<1", "<2", .. | a fold with this level ends at this line |
| ">1", ">2", .. | a fold with this level starts at this line |

The result values "=", "s" and "a" are more expensive, please see [fold-expr-slow](#) .

It is not required to mark the start (end) of a fold with ">1" ("<1"), a fold will also start (end) when the fold level is higher (lower) than the fold level of the previous line.

There must be no side effects from the expression. The text in the buffer, cursor position, the search patterns, options etc. must not be changed. You can change and restore them if you are careful.

If there is some error in the expression, or the resulting value isn't recognized, there is no error message and the fold level will be zero. For debugging the **'debug'** option can be set to "msg", the error messages will be visible then.

If the **'foldexpr'** expression starts with s: or <SID> , then it is replaced with the script ID ([local-function](#)). Examples:

```
set foldexpr=s:MyFoldExpr()
set foldexpr=<SID>SomeFoldExpr()
```

An example of using "a1" and "s1": For a multi-line C comment, a line containing "/*" would return "a1" to start a fold, and a line containing "*/" would return "s1" to end the fold after that line:

```
if match(thisline, '/*') >= 0
    return 'a1'
elseif match(thisline, '*/') >= 0
    return 's1'
else
    return '='
endif
```

However, this won't work for single line comments, strings, etc.

[foldlevel\(\)](#) can be useful to compute a fold level relative to a previous fold level. But **note** that [foldlevel\(\)](#) may return -1 if the level is not known yet. And it returns the level at the start of the line, while a fold might end in that line.

It may happen that folds are not updated properly. You can use [zx](#) or [zX](#) to force updating folds.

MINIMIZING COMPUTATIONAL COST

[fold-expr-slow](#)

Due to its computational cost, this fold method can make Vim unresponsive, especially when the fold level of all lines have to be initially computed. Afterwards, after each change, Vim restricts the computation of foldlevels to those lines whose fold level was affected by it (and reuses the known foldlevels of all the others).

The fold expression should therefore strive to minimize the number of dependent lines needed for the computation of a given line: For example, try to avoid the "=", "a" and "s" return values, because these will require the evaluation of the fold levels on previous lines until an independent fold level is found.

If this proves difficult, the next best thing could be to cache all fold levels in a buffer-local variable (`b:foldlevels`) that is only updated on `b:changedtick` :

```
>vim
vim9script
def MyFoldFunc(): number
    if b:lasttick == b:changedtick
        return b:foldlevels[v:lnum - 1]
    endif
    b:lasttick = b:changedtick
    b:foldlevels = []
    # compute foldlevels ...
    return b:foldlevels[v:lnum - 1]
enddef
set foldexpr=s:MyFoldFunc()
<
```

In above example further speedup was gained by using a precompiled Vim9 script function without arguments (that must still use `v:lnum`). See [expr-option-function](#) .

SYNTAX

fold-syntax

A fold is defined by syntax items that have the "fold" argument. `:syn-fold`

The fold level is defined by nesting folds. The nesting of folds is limited with `'foldnestmax'`.

Be careful to specify proper syntax syncing. If this is not done right, folds may differ from the displayed highlighting. This is especially relevant when using patterns that match more than one line. In case of doubt, try using brute-force syncing:

```
:syn sync fromstart
```

DIFF

fold-diff

The folds are automatically defined for text that is not part of a change or close to a change.

This method only works properly when the `'diff'` option is set for the current window and changes are being displayed. Otherwise the whole buffer will be one big fold.

The `'diffopt'` option can be used to specify the context. That is, the number of lines between the fold and a change that are not included in the fold. For example, to use a context of 8 lines:

```
:set diffopt=filler,context:8
```

The default context is six lines.

When `'scrollbind'` is also set, Vim will attempt to keep the same folds open in other diff windows, so that the same text is visible.

MARKER

fold-marker

Markers in the text tell where folds start and end. This allows you to precisely specify the folds. This will allow deleting and putting a fold, without the risk of including the wrong lines. The `'foldtext'` option is normally set such that the text before the marker shows up in the folded line. This makes it possible to give a name to the fold.

Markers can have a level included, or can use matching pairs. Including a level is easier, you don't have to add end markers and avoid problems with non-matching marker pairs. Example:

```
/* global variables {{{1 */  
int varA, varB;
```

```
/* functions {{{1 */  
/* funcA() {{{2 */  
void funcA() {}
```

```
/* funcB() {{{2 */  
void funcB() {}
```

```
{{{  }}}
```

A fold starts at a `"{{{"` marker. The following number specifies the fold level. What happens depends on the difference between the current fold level and the level given by the marker:

1. If a marker with the same fold level is encountered, the previous fold ends and another fold with the same level starts.
2. If a marker with a higher fold level is found, a nested fold is started.
3. If a marker with a lower fold level is found, all folds up to and including this level end and a fold with the specified level starts.

The number indicates the fold level. A zero cannot be used (a marker with level zero is ignored). You can use `"}}}"` with a digit to indicate the level of the fold that ends. The fold level of the following line will be one less than the indicated level. **Note** that Vim doesn't look back to the level of the matching marker (that would take too much time). Example:

```
{{{1  
fold level here is 1  
{{{3  
fold level here is 3  
}}}3  
fold level here is 2
```

You can also use matching pairs of `"{{{"` and `"}}}"` markers to define folds. Each `"{{{"` increases the fold level by one, each `"}}}"` decreases the fold level by one. Be careful to keep the markers matching! Example:

```
{{{  
fold level here is 1  
{{{  
fold level here is 2  
}}}  
fold level here is 1
```

You can mix using markers with a number and without a number. A useful way of doing this is to use numbered markers for large folds, and unnumbered markers locally in a function. For example use level one folds for the sections of your file like "structure definitions", "local variables" and "functions". Use level 2 markers for each definition and function, Use unnumbered markers inside functions. When you make changes in a function to split up folds, you don't have to renumber the markers.

The markers can be set with the **'foldmarker'** option. It is recommended to keep this at the default value of "**{{{,}}}**", so that files can be exchanged between Vim users. Only change it when it is required for the file (e.g., it contains markers from another folding editor, or the default markers cause trouble for the language of the file).

fold-create-marker

"zf" can be used to create a fold defined by markers. Vim will insert the markers for you. Vim will append the start and end marker, as specified with **'foldmarker'**. The markers are appended to the end of the line.

'commentstring' is used if it isn't empty.

This does not work properly when:

- The line already contains a marker with a level number. Vim then doesn't know what to do.
- Folds nearby use a level number in their marker which gets in the way.
- The line is inside a comment, **'commentstring'** isn't empty and nested comments don't work. For example with C: adding `/* {{{ */` inside a comment will truncate the existing comment. Either put the marker before or after the comment, or add the marker manually.

Generally it's not a good idea to let Vim create markers when you already have markers with a level number.

fold-delete-marker

"zd" can be used to delete a fold defined by markers. Vim will delete the markers for you. Vim will search for the start and end markers, as specified with **'foldmarker'**, at the start and end of the fold. When the text around the marker matches with **'commentstring'**, that text is deleted as well.

This does not work properly when:

- A line contains more than one marker and one of them specifies a level. Only the first one is removed, without checking if this will have the desired effect of deleting the fold.
- The marker contains a level number and is used to start or end several folds at the same time.

2. Fold commands

fold-commands E490

All folding commands start with "z". Hint: the "z" looks like a folded piece of paper, if you look at it from the side.

CREATING AND DELETING FOLDS

zf E350

zf{motion} or

{Visual}zf Operator to create a fold.

This only works when **'foldmethod'** is "manual" or "marker".

The new fold will be closed for the "manual" method.
'**foldenable**' will be set.
Also see [fold-create-marker](#) .

- zF** zF
Create a fold for [count] lines. Works like "zf".
- :{range}fo[ld]** :fold :fo
Create a fold for the lines in {range}. Works like "zf".
- zd** zd E351
Delete one fold at the cursor. When the cursor is on a folded line, that fold is deleted. Nested folds are moved one level up. In Visual mode one level of all folds (partially) in the selected area are deleted.
Careful: This easily deletes more folds than you expect and there is no undo for manual folding.
This only works when '**foldmethod**' is "manual" or "marker".
Also see [fold-delete-marker](#) .
- zD** zD
Delete folds recursively at the cursor. In Visual mode all folds (partially) in the selected area and all nested folds in them are deleted.
This only works when '**foldmethod**' is "manual" or "marker".
Also see [fold-delete-marker](#) .
- zE** zE E352
Eliminate all folds in the window.
This only works when '**foldmethod**' is "manual" or "marker".
Also see [fold-delete-marker](#) .

OPENING AND CLOSING FOLDS

A fold smaller than '**foldminlines**' will always be displayed like it was open. Therefore the commands below may work differently on small folds.

- zo** zo
Open one fold under the cursor. When a count is given, that many folds deep will be opened. In Visual mode one level of folds is opened for all lines in the selected area.
- zO** zO
Open all folds under the cursor recursively. Folds that don't contain the cursor line are unchanged.
In Visual mode it opens all folds that are in the selected area, also those that are only partly selected.
- zc** zc
Close one fold under the cursor. When a count is given, that many folds deep are closed. In Visual mode one level of folds is closed for all lines in the selected area.
'**foldenable**' will be set.

- zC** Close all folds under the cursor recursively. Folds that don't contain the cursor line are unchanged. In Visual mode it closes all folds that are in the selected area, also those that are only partly selected. **'foldenable'** will be set.
- za** Summary: Toggle the fold under the cursor. When on a closed fold: open it. When folds are nested, you may have to use "za" several times. When a count is given, that many closed folds are opened. When on an open fold: close it and set **'foldenable'**. This will only close one level, since using "za" again will open the fold. When a count is given that many folds will be closed (that's not the same as repeating "za" that many times).
- zA** When on a closed fold: open it recursively. When on an open fold: close it recursively and set **'foldenable'**.
- zv** View cursor line: Open just enough folds to make the line in which the cursor is located not folded.
- zx** Update folds: Undo manually opened and closed folds: re-apply **'foldlevel'**, then do "zv": View cursor line. Also forces recomputing folds. This is useful when using **'foldexpr'** and the buffer is changed in a way that results in folds not to be updated properly.
- zX** Undo manually opened and closed folds: re-apply **'foldlevel'**. Also forces recomputing folds, like **zx**.
- zm** Fold more: Subtract **v:count1** from **'foldlevel'**. If **'foldlevel'** was already zero nothing happens. **'foldenable'** will be set.
- zM** Close all folds: set **'foldlevel'** to 0. **'foldenable'** will be set.
- zr** Reduce folding: Add **v:count1** to **'foldlevel'**.
- zR** Open all folds. This sets **'foldlevel'** to highest fold level.

:foldo :foldopen

`:{range}foldo[pen][!]`
Open folds in `{range}`. When `!` is added all folds are opened. Useful to see all the text in `{range}`. Without `!` one level of folds is opened.

:foldc :foldclose

`:{range}foldc[lose][!]`
Close folds in `{range}`. When `!` is added all folds are closed. Useful to hide all the text in `{range}`. Without `!` one level of folds is closed.

zn

zn Fold none: reset `'foldenable'`. All folds will be open.

zN

zN Fold normal: set `'foldenable'`. All folds will be as they were before.

zi

zi Invert `'foldenable'`.

MOVING OVER FOLDS

[z

[z Move to the start of the current open fold. If already at the start, move to the start of the fold that contains it. If there is no containing fold, the command fails. When a count is used, repeats the command `[count]` times.

]z

]z Move to the end of the current open fold. If already at the end, move to the end of the fold that contains it. If there is no containing fold, the command fails. When a count is used, repeats the command `[count]` times.

zj

zj Move downwards to the start of the next fold. A closed fold is counted as one fold. When a count is used, repeats the command `[count]` times. This command can be used after an `operator` .

zk

zk Move upwards to the end of the previous fold. A closed fold is counted as one fold. When a count is used, repeats the command `[count]` times. This command can be used after an `operator` .

EXECUTING COMMANDS ON FOLDS

:foldd :folddo :folddoopen

`:[range]foldd[open] {cmd}`
Execute `{cmd}` on all lines that are not in a closed fold. When `[range]` is given, only these lines are used.

Each time `{cmd}` is executed the cursor is positioned on the line it is executed for.

This works like the `":global"` command: First all lines that are not in a closed fold are marked. Then the `{cmd}` is executed for all marked lines. Thus when `{cmd}` changes the folds, this has no influence on where it is executed (except when lines are deleted, of course).

Example:

```
:folddoopen s/end/loop_end/ge
```

Note the use of the "e" flag to avoid getting an error message where "end" doesn't match.

```
:[range]folddoc[losed] {cmd} :folddoc :folddoclosed  
Execute {cmd} on all lines that are in a closed fold.  
Otherwise like ":folddoopen".
```

3. Fold options

fold-options

COLORS

fold-colors

The colors of a closed fold are set with the Folded group `hl-Folded`. The colors of the fold column are set with the FoldColumn group `hl-FoldColumn`. Example to set the colors:

```
:highlight Folded guibg=grey guifg=blue  
:highlight FoldColumn guibg=darkgrey guifg=white
```

FOLDLEVEL

fold-foldlevel

'**foldlevel**' is a number option: The higher the more folded regions are open.

When '**foldlevel**' is 0, all folds are closed.

When '**foldlevel**' is positive, some folds are closed.

When '**foldlevel**' is very high, all folds are open.

'**foldlevel**' is applied when it is changed. After that manually folds can be opened and closed.

When increased, folds above the new level are opened. No manually opened folds will be closed.

When decreased, folds above the new level are closed. No manually closed folds will be opened.

FOLDTEXT

fold-foldtext

'**foldtext**' is a string option that specifies an expression. This expression is evaluated to obtain the text displayed for a closed fold. Example:

```
:set foldtext=v:folddashes.substitute(getline(v:foldstart),'/\*\\|\\*/\\|\\{\\{\\d\\}='
```

This shows the first line of the fold, with `"/*`, `*/` and `"{{{` removed.

Note the use of backslashes to avoid some characters to be interpreted by the `":set"` command. It is much simpler to define a function and call it:

```

:set foldtext=MyFoldText()
:function MyFoldText()
: let line = getline(v:foldstart)
: let sub = substitute(line, '/\*\|*\|*\/\|{\d\|=\|', '', 'g')
: return v:folddashes .. sub
:endfunction

```

The advantage of using a function call without arguments is that it is faster, see [expr-option-function](#) .

Evaluating **'foldtext'** is done in the [sandbox](#) . The current window is set to the window that displays the line. The context is set to the script where the option was last set.

Errors are ignored. For debugging set the **'debug'** option to "throw".

The default value is `foldtext()` . This returns a reasonable text for most types of folding. If you don't like it, you can specify your own **'foldtext'** expression. It can use these special Vim variables:

| | |
|---------------------------|---|
| <code>v:foldstart</code> | line number of first line in the fold |
| <code>v:foldend</code> | line number of last line in the fold |
| <code>v:folddashes</code> | a string that contains dashes to represent the foldlevel. |
| <code>v:foldlevel</code> | the foldlevel of the fold |

In the result a TAB is replaced with a space and unprintable characters are made into printable characters.

The resulting line is truncated to fit in the window, it never wraps. When there is room after the text, it is filled with the character specified by **'fillchars'**.

If the **'foldtext'** expression starts with `s:` or `<SID>` , then it is replaced with the script ID ([local-function](#)). Examples:

```

set foldtext=s:MyFoldText()
set foldtext=<SID>SomeFoldText()

```

Note that backslashes need to be used for characters that the `":set"` command handles differently: Space, backslash and double-quote. [option-backslash](#)

FOLDCOLUMN

fold-foldcolumn

'foldcolumn' is a number, which sets the width for a column on the side of the window to indicate folds. When it is zero, there is no foldcolumn. A normal value is 4 or 5. The minimal useful value is 2, although 1 still provides some information. The maximum is 12.

An open fold is indicated with a column that has a '-' at the top and '|' characters below it. This column stops where the open fold stops. When folds nest, the nested fold is one character right of the fold it's contained in.

A closed fold is indicated with a '+'.

These characters can be changed with the `'fillchars'` option.

Where the fold column is too narrow to display all nested folds, digits are shown to indicate the nesting level.

The mouse can also be used to open and close folds by clicking in the fold column:

- Click on a '+' to open the closed fold at this row.
- Click on any other non-blank character to close the open fold at this row.

OTHER OPTIONS

| | | |
|-----------------------------|----------------------|---|
| <code>'foldenable'</code> | <code>'fen'</code> : | Open all folds while not set. |
| <code>'foldexpr'</code> | <code>'fde'</code> : | Expression used for "expr" folding. |
| <code>'foldignore'</code> | <code>'fdi'</code> : | Characters used for "indent" folding. |
| <code>'foldmarker'</code> | <code>'fmr'</code> : | Defined markers used for "marker" folding. |
| <code>'foldmethod'</code> | <code>'fdm'</code> : | Name of the current folding method. |
| <code>'foldminlines'</code> | <code>'fml'</code> : | Minimum number of screen lines for a fold to be displayed closed. |
| <code>'foldnestmax'</code> | <code>'fdn'</code> : | Maximum nesting for "indent" and "syntax" folding. |
| <code>'foldopen'</code> | <code>'fdo'</code> : | Which kinds of commands open closed folds. |
| <code>'foldclose'</code> | <code>'fcl'</code> : | When the folds not under the cursor are closed. |

4. Behavior of folds

fold-behavior

When moving the cursor upwards or downwards and when scrolling, the cursor will move to the first line of a sequence of folded lines. When the cursor is already on a folded line, it moves to the next unfolded line or the next closed fold.

While the cursor is on folded lines, the cursor is always displayed in the first column. The ruler does show the actual cursor position, but since the line is folded, it cannot be displayed there.

Many movement commands handle a sequence of folded lines like an empty line. For example, the "w" command stops once in the first column.

When starting a search in a closed fold it will not find a match in the current fold. It's like a forward search always starts from the end of the closed fold, while a backwards search starts from the start of the closed fold.

When in Insert mode, the cursor line is never folded. That allows you to see what you type!

When using an operator, a closed fold is included as a whole. Thus "dl" deletes the whole closed fold under the cursor.

For Ex commands that work on buffer lines the range is adjusted to always start at the first line of a closed fold and end at the last line of a closed fold. Thus this command:

```
:s/foo/bar/g
```

when used with the cursor on a closed fold, will replace "foo" with "bar" in all lines of the fold.

This does not happen for `:folddoopen` and `:folddoclosed` .

When editing a buffer that has been edited before, the last used folding settings are used again. For manual folding the defined folds are restored. For all folding methods the manually opened and closed folds are restored. If this buffer has been edited in this window, the values from back then are used. Otherwise the values from the window where the buffer was edited last are used.

=====

Testing Vim and Vim script

[testing-support](#)

Expression evaluation is explained in [eval.txt](#) . This file goes into details about writing tests in Vim script. This can be used for testing Vim itself and for testing plugins.

- 1. Testing Vim [testing](#)
- 2. Test functions [test-functions-details](#)
- 3. Assert functions [assert-functions-details](#)

1. Testing Vim

[testing](#)

Vim can be tested after building it, usually with "make test". The tests are located in the directory "src/testdir".

There are two types of tests added over time:

| | |
|--------------------|------------------------------|
| test20.in | oldest, only for tiny builds |
| test_something.vim | new style tests |

[new-style-testing](#)

New tests should be added as new style tests. The test scripts are named test_<feature>.vim (replace <feature> with the feature under test). These use functions such as [assert_equal\(\)](#) to keep the test commands and the expected result in one place.

[old-style-testing](#)

These tests are used only for testing Vim without the [+eval](#) feature.

Find more information in the file src/testdir/README.txt.

2. Test functions

[test-functions-details](#)

test_alloc_fail({id}, {countdown}, {repeat}) [test_alloc_fail\(\)](#)

This is for testing: If the memory allocation with {id} is called, then decrement {countdown}, and when it reaches zero let memory allocation fail {repeat} times. When {repeat} is smaller than one it fails one time.

Can also be used as a [method](#) :

[GetAllocId\(\)->test_alloc_fail\(\)](#)

Return type: [Number](#)

test_autochdir()

[test_autochdir\(\)](#)

Set a flag to enable the effect of ['autochdir'](#) before Vim startup has finished.

Return type: `Number`

`test_feedinput({string})` `test_feedinput()`
Characters in `{string}` are queued for processing as if they were typed by the user. This uses a low level input buffer. This function works only when with `+unix` or GUI is running.

Can also be used as a `method` :
`GetText()->test_feedinput()`

Return type: `Number`

`test_garbagecollect_now()` `test_garbagecollect_now()`
Like `garbagecollect()`, but executed right away. This must only be called directly to avoid any structure to exist internally, and `v:testing` must have been set before calling any function. `E1142`
This will not work when called from a `:def` function, because variables on the stack will be freed.

Return type: `Number`

`test_garbagecollect_soon()` `test_garbagecollect_soon()`
Set the flag to call the garbagecollector as if in the main loop. Only to be used in tests.

Return type: `Number`

`test_getvalue({name})` `test_getvalue()`
Get the value of an internal variable. These values for `{name}` are supported:
`need_fileinfo`

Can also be used as a `method` :
`GetName()->test_getvalue()`

Return type: `Number`

`test_gui_event({event}, {args})` `test_gui_event()`
Generate a GUI `{event}` with arguments `{args}` for testing Vim functionality. This function works only when the GUI is running.

`{event}` is a String and the supported values are:
"dropfiles" drop one or more files in a window.
"findrepl" search and replace text.
"mouse" mouse button click event.
"scrollbar" move or drag the scrollbar.
"key" send a low-level keyboard event.
"tabline" select a tab page by mouse click.

"tabmenu" select a tabline menu entry.

{args} is a Dict and contains the arguments for the event.

"dropfiles":

Drop one or more files in a specified window. The supported items in {args} are:

files: List of file names
row: window row number
col: window column number
modifiers: key modifiers. The supported values are:
0x4 Shift
0x8 Alt
0x10 Ctrl

The files are added to the `argument-list` and the first file in {files} is edited in the window. See `drag-n-drop` for more information. This event works only when the `drop_file` feature is present.

"findrepl":

{only available when the GUI has a find/replace dialog}

Perform a search and replace of text. The supported items in {args} are:

find_text: string to find.
repl_text: replacement string.
flags: flags controlling the find/replace. Supported values are:
1 search next string (find dialog)
2 search next string (replace dialog)
3 replace string once
4 replace all matches
8 match whole words only
16 match case
forward: set to 1 for forward search.

"mouse":

Inject either a mouse button click, or a mouse move, event. The supported items in {args} are:

button: mouse button. The supported values are:
0 left mouse button
1 middle mouse button
2 right mouse button
3 mouse button release
4 scroll wheel down
5 scroll wheel up
6 scroll wheel left
7 scroll wheel right

row: mouse click row number. The first row of the Vim window is 1 and the last row is '`lines`'.

col: mouse click column number. The maximum value of {col} is '`columns`'.

multiclick: set to 1 to inject a multiclick mouse event.

modifiers: key modifiers. The supported values are:
4 shift is pressed

8 alt is pressed
 16 ctrl is pressed
 move: Optional; if used and TRUE then a mouse move event can be generated. Only {args} row: and col: are used and required; they are interpreted as pixels or screen cells, depending on "cell". Only results in an event when 'mousemoveevent' is set or a popup uses mouse move events.
 cell: Optional: when present and TRUE then "move" uses screen cells instead of pixel positions

"scrollbar":
 Set or drag the left, right or horizontal scrollbar. Only works when the scrollbar actually exists. The supported items in {args} are:
 which: Selects the scrollbar. The supported values are:
 left Left scrollbar of the current window
 right Right scrollbar of the current window
 hor Horizontal scrollbar
 value: Amount to scroll. For the vertical scrollbars the value can be between 0 to the line-count of the buffer minus one. For the horizontal scrollbar the value can be between 1 and the maximum line length, assuming 'wrap' is not set.
 dragging: 1 to drag the scrollbar and 0 to click in the scrollbar.

"key":
 Send a low-level keyboard event (e.g. key-up or down). Currently only supported on MS-Windows. The supported items in {args} are:
 event: The supported string values are:
 keyup generate a keyup event
 keydown generate a keydown event
 keycode: Keycode to use for a keyup or a keydown event.

"tabline":
 Inject a mouse click event on the tabline to select a tabpage. The supported items in {args} are:
 tabnr: tab page number

"tabmenu":
 Inject an event to select a tabline menu entry. The supported items in {args} are:
 tabnr: tab page number
 item: tab page menu item number. 1 for the first menu item, 2 for the second item and so on.

After injecting the GUI events you probably should call `feedkeys()` to have them processed, e.g.:

call `feedkeys("y", 'Lx!')`

Returns TRUE if the event is successfully added, FALSE if there is a failure.

Can also be used as a `method` :

`GetEvent()->test_gui_event({args})`

Return type: `vim9-boolean`

`test_ignore_error({expr})`

`test_ignore_error()`

Ignore any error containing `{expr}`. A normal message is given instead.

This is only meant to be used in tests, where catching the error with try/catch cannot be used (because it skips over following code).

`{expr}` is used literally, not as a pattern.

When the `{expr}` is the string "RESET" then the list of ignored errors is made empty.

Can also be used as a `method` :

`GetErrorText()->test_ignore_error()`

Return type: `Number`

`test_mswin_event({event}, {args})`

`test_mswin_event()`

Generate a low-level MS-Windows `{event}` with arguments `{args}` for testing Vim functionality. It works for MS-Windows GUI and for the console.

`{event}` is a String and the supported values are:

"mouse" mouse event.
"key" keyboard event.
"set_keycode_trans_strategy"
Change the key translation method.

"mouse":

Inject either a mouse button click, or a mouse move, event.

The supported items in `{args}` are:

button: mouse button. The supported values are:
0 right mouse button
1 middle mouse button
2 left mouse button
3 mouse button release
4 scroll wheel down
5 scroll wheel up
6 scroll wheel left
7 scroll wheel right

row: mouse click row number. The first row of the Vim window is 1 and the last row is '`lines`'.

col: mouse click column number. The maximum value of `{col}` is '`columns`'.

Note: row and col are always interpreted as screen cells for the console application.

But, they may be interpreted as pixels for the GUI, depending on "cell".

multiclick: set to 1 to inject a double-click mouse event.

modifiers: key modifiers. The supported values are:

- 4 shift is pressed
- 8 alt is pressed
- 16 ctrl is pressed

move: Optional; if used and TRUE then a mouse move event can be generated. Only {args} row: and col: are used and required. Only results in an event when 'mousemoveevent' is set or a popup uses mouse move events.

cell: Optional for the GUI: when present and TRUE then "move" uses screen cells instead of pixel positions. Not used by the console.

"key":
Send a low-level keyboard event (e.g. keyup or keydown). The supported items in {args} are:

event: The supported string values are:

- keyup generate a keyup event
- keydown generate a keydown event

keycode: Keycode to use for a keyup or a keydown event.

modifiers: Optional; key modifiers. The supported values are:

- 2 shift is pressed
- 4 ctrl is pressed
- 8 alt is pressed

Note: These values are different from the mouse modifiers.

execute: Optional. Similar to `feedkeys()` mode x. When this is included and set to true (non-zero) then Vim will process any buffered unprocessed key events. All other {args} items are optional when this is set and true.

"set_keycode_trans_strategy":
[w32-experimental-keycode-trans-strategy](#)
Switch the keycode translation method. The supported methods are:

- experimental: The method used after Patch v8.2.4807 using ToUnicode() Win API call.
- classic: The method used pre Patch v8.2.4807 using the TranslateMessage() Win API call.

Returns TRUE if the event is successfully added or executed, FALSE if there is a failure.

Can also be used as a `method` :

```
GetEvent()->test_mswin_event({args})
```

Return type: `vim9-boolean`

`test_null_blob()` `test_null_blob()`
 Return a `Blob` that is null. Only useful for testing.
 Return type: `Blob`

`test_null_channel()` `test_null_channel()`
 Return a `Channel` that is null. Only useful for testing.
 {only available when compiled with the `+channel` feature}
 Return type: `Channel`

`test_null_dict()` `test_null_dict()`
 Return a `Dict` that is null. Only useful for testing.
 Return type: `dict<any>`

`test_null_function()` `test_null_function()`
 Return a `Funcref` that is null. Only useful for testing.
 Return type: `func(...): unknown`

`test_null_job()` `test_null_job()`
 Return a `Job` that is null. Only useful for testing.
 {only available when compiled with the `+job` feature}
 Return type: `job`

`test_null_list()` `test_null_list()`
 Return a `List` that is null. Only useful for testing.
 Return type: `list<any>`

`test_null_partial()` `test_null_partial()`
 Return a `Partial` that is null. Only useful for testing.
 Return type: `func(...): unknown`

`test_null_string()` `test_null_string()`
 Return a `String` that is null. Only useful for testing.
 Return type: `String`

`test_option_not_set({name})` `test_option_not_set()`
 Reset the flag that indicates option `{name}` was set. Thus it looks like it still has the default value. Use like this:

```

set ambiwidth=double
call test_option_not_set('ambiwidth')

```

 Now the `'ambiwidth'` option behaves like it was never changed, even though the value is "double".
 Only to be used for testing!

 Can also be used as a `method` :

```

GetOptionName()->test_option_not_set()

```

Return type: `Number`

`test_override({name}, {val})` `test_override()`
Overrides certain parts of Vim's internal processing to be able to run tests. Only to be used for testing Vim!
The override is enabled when `{val}` is non-zero and removed when `{val}` is zero.
Current supported values for `{name}` are:

| <code>{name}</code> | effect when <code>{val}</code> is non-zero |
|-----------------------------|---|
| <code>alloc_lines</code> | make a copy of every buffer line into allocated memory, so that memory access errors can be found by <code>valgrind</code> . |
| <code>autoload</code> | <code>`import autoload`</code> will load the script right away, not postponed until an item is used. |
| <code>char_avail</code> | disable the <code>char_avail()</code> function. |
| <code>defcompile</code> | all the <code>:def</code> functions in a sourced script are compiled when defined. This is similar to using the <code>:defcompile</code> command in a script. |
| <code>nfa_fail</code> | makes the NFA regexp engine fail to force a fallback to the old engine. |
| <code>no_query_mouse</code> | do not query the mouse position for "dec" terminals. |
| <code>no_wait_return</code> | set the "no_wait_return" flag. Not restored with "ALL". |
| <code>redraw</code> | disable the <code>redrawing()</code> function. |
| <code>redraw_flag</code> | ignore the <code>RedrawingDisabled</code> flag. |
| <code>starting</code> | reset the "starting" variable, see below. |
| <code>term_props</code> | reset all terminal properties when the version string is detected. |
| <code>ui_delay</code> | time in msec to use in <code>ui_delay()</code> ; overrules a wait time of up to 3 seconds for messages. |
| <code>unreachable</code> | no error for code after <code>`:throw`</code> and <code>`:return`</code> . |
| <code>uptime</code> | overrules <code>sysinfo.uptime</code> . |
| <code>vterm_title</code> | setting the window title by a job running in a terminal window. |
| ALL | clear all overrides, except <code>alloc_lines</code> (<code>{val}</code> is not used). |

"starting" is to be used when a test should behave like startup was done. Since the tests are run by sourcing a script the "starting" variable is non-zero. This is usually a good thing (tests run faster), but sometimes this changes behavior in a way that the test doesn't work properly.

When using:

```
call test_override('starting', 1)
```

The value of "starting" is saved. It is restored by:

```
call test_override('starting', 0)
```

To make sure the flag is reset later using ``:defer`` can be useful:

```
call test_override('unreachable', 1)
defer call test_override('unreachable', 0)
```

Can also be used as a `method` :
`GetOverrideVal()-> test_override('starting')`

Return type: `Number`

`test_refcount({expr})` `test_refcount()`
Return the reference count of `{expr}`. When `{expr}` is of a type that does not have a reference count, returns -1. Only to be used for testing.

Can also be used as a `method` :
`GetVarname()->test_refcount()`

Return type: `Number`

`test_setmouse({row}, {col})` `test_setmouse()`
Set the mouse position to be used for the next mouse action. `{row}` and `{col}` are one based.
For example:

```
call test_setmouse(4, 20)
call feedkeys("\<LeftMouse>", "xt")
```

Return type: `Number`

`test_settime({expr})` `test_settime()`
Set the time Vim uses internally. Currently only used for timestamps in the history, as they are used in viminfo, and for undo.
Using a value of 1 makes Vim not sleep after a warning or error message.
`{expr}` must evaluate to a number. When the value is zero the normal behavior is restored.

Can also be used as a `method` :
`GetTime()->test_settime()`

Return type: `Number`

`test_srand_seed([seed])` `test_srand_seed()`
When `{seed}` is given this sets the seed value used by ``srand()``. When omitted the test seed is removed.

Return type: `Number`

`test_unknown()` `test_unknown()`
Return a value with unknown type. Only useful for testing.

Return type: `unknown`

`test_void()` `test_void()`
Return a value with void type. Only useful for testing.

Return type: `void`

3. Assert functions

assert-functions-details

assert_beeps({cmd})

assert_beeps()

Run {cmd} and add an error message to `v:errors` if it does NOT produce a beep or visual bell. Also see `assert_fails()`, `assert_nobeep()` and `assert-return`.

Can also be used as a method :
`GetCmd()->assert_beeps()`

Return type: `Number`

assert_equal({expected}, {actual} [, {msg}])

assert_equal()

When {expected} and {actual} are not equal an error message is added to `v:errors` and 1 is returned. Otherwise zero is returned. `assert-return`

The error is in the form "Expected {expected} but got {actual}". When {msg} is present it is prefixed to that, along with the location of the assert when run from a script.

There is no automatic conversion, the String "4" is different from the Number 4. And the number 4 is different from the Float 4.0. The value of '`ignorecase`' is not used here, case always matters.

Example:

```
call assert_equal('foo', 'bar', 'baz')
```

Will add the following to `v:errors` :

```
test.vim line 12: baz: Expected 'foo' but got 'bar'
```

Can also be used as a method , the base is passed as the second argument:

```
mylist->assert_equal([1, 2, 3])
```

Return type: `Number`

assert_equalfile({fname-one}, {fname-two} [, {msg}])

assert_equalfile()

When the files {fname-one} and {fname-two} do not contain exactly the same text an error message is added to `v:errors`. Also see `assert-return`.

When {fname-one} or {fname-two} does not exist the error will mention that.

Mainly useful with `terminal-diff`.

Can also be used as a method :

```
GetLog()->assert_equalfile('expected.log')
```

Return type: `Number`

`assert_exception({error} [, {msg}])`

`assert_exception()`

When `v:exception` does not contain the string `{error}` an error message is added to `v:errors`. Also see `assert-return`. This can be used to assert that a command throws an exception. Using the error number, followed by a colon, avoids problems with translations:

```
try
  commandthatfails
  call assert_false(1, 'command should have failed')
catch
  call assert_exception('E492:')
endtry
```

Return type: `Number`

`assert_fails({cmd} [, {error} [, {msg} [, {lnum} [, {context}]]]])`

`assert_fails()`

Run `{cmd}` and add an error message to `v:errors` if it does NOT produce an error or when `{error}` is not found in the error message. Also see `assert-return`.

`E856`

When `{error}` is a string it must be found literally in the first reported error. Most often this will be the error code, including the colon, e.g. "E123:".

```
call assert_fails('bad cmd', 'E987:')
```

When `{error}` is a `List` with one or two strings, these are used as patterns. The first pattern is matched against the first reported error:

```
call assert_fails('cmd', ['E987:.*expected bool'])
```

The second pattern, if present, is matched against the last reported error.

If there is only one error then both patterns must match. This can be used to check that there is only one error.

To only match the last error use an empty string for the first error:

```
call assert_fails('cmd', ['', 'E987:'])
```

If `{msg}` is empty then it is not used. Do this to get the default message when passing the `{lnum}` argument.

`E1115`

When `{lnum}` is present and not negative, and the `{error}` argument is present and matches, then this is compared with the line number at which the error was reported. That can be the line number in a function or in a script.

`E1116`

When `{context}` is present it is used as a pattern and matched against the context (script name or function name) where `{lnum}` is located in.

Note that beeping is not considered an error, and some failing commands only beep. Use `assert_beeps()` for those.

Can also be used as a `method` :

`GetCmd()->assert_fails('E99:')`

Return type: `Number`

`assert_false({actual} [, {msg}])` `assert_false()`
When `{actual}` is not false an error message is added to `v:errors`, like with `assert_equal()`. The error is in the form "Expected False but got `{actual}`". When `{msg}` is present it is prefixed to that, along with the location of the assert when run from a script. Also see `assert-return`.

A value is false when it is zero. When `{actual}` is not a number the assert fails.

Can also be used as a `method` :
`GetResult()->assert_false()`

Return type: `Number`

`assert_inrange({lower}, {upper}, {actual} [, {msg}])` `assert_inrange()`
This asserts number and `Float` values. When `{actual}` is lower than `{lower}` or higher than `{upper}` an error message is added to `v:errors`. Also see `assert-return`. The error is in the form "Expected range `{lower} - {upper}`, but got `{actual}`". When `{msg}` is present it is prefixed to that.

Return type: `Number`

`assert_match({pattern}, {actual} [, {msg}])` `assert_match()`
When `{pattern}` does not match `{actual}` an error message is added to `v:errors`. Also see `assert-return`. The error is in the form "Pattern `{pattern}` does not match `{actual}`". When `{msg}` is present it is prefixed to that, along with the location of the assert when run from a script.

`{pattern}` is used as with `=~`: The matching is always done like `'magic'` was set and `'coptions'` is empty, no matter what the actual value of `'magic'` or `'coptions'` is.

`{actual}` is used as a string, automatic conversion applies. Use `"^"` and `"$"` to match with the start and end of the text. Use both to match the whole text.

Example:

`call assert_match('^f.*$', 'foobar')`

Will result in a string to be added to `v:errors` :

`test.vim line 12: Pattern '^f.*$' does not match 'foobar'`

Can also be used as a `method` :
`getFile()->assert_match('foo.*')`

Return type: `Number`

`assert_nobeep({cmd})` `assert_nobeep()`
Run `{cmd}` and add an error message to `v:errors` if it produces a beep or visual bell.
Also see `assert_beeps()` .

Can also be used as a `method` :
`GetCmd()->assert_nobeep()`

Return type: `Number`

`assert_notequal({expected}, {actual} [, {msg}])` `assert_notequal()`
The opposite of ``assert_equal()``: add an error message to `v:errors` when `{expected}` and `{actual}` are equal.
Also see `assert-return` .

Can also be used as a `method` :
`mylist->assert_notequal([1, 2, 3])`

Return type: `Number`

`assert_notmatch({pattern}, {actual} [, {msg}])` `assert_notmatch()`
The opposite of ``assert_match()``: add an error message to `v:errors` when `{pattern}` matches `{actual}`.
Also see `assert-return` .

Can also be used as a `method` :
`getFile()->assert_notmatch('bar.*')`

Return type: `Number`

`assert_report({msg})` `assert_report()`
Report a test failure directly, using String `{msg}`.
Always returns one.

Can also be used as a `method` :
`GetMessage()->assert_report()`

Return type: `Number`

`assert_true({actual} [, {msg}])` `assert_true()`
When `{actual}` is not true an error message is added to `v:errors` , like with `assert_equal()` .
Also see `assert-return` .
A value is TRUE when it is a non-zero number. When `{actual}` is not a number the assert fails.
When `{msg}` is given it is prefixed to the default message, along with the location of the assert when run from a script.

Can also be used as a `method` :

`GetResult()->assert_true()`

Return type: `Number`

Printing

{only available when compiled with the |+printer| feature}

=====

1. Introduction print-intro

On MS-Windows Vim can print your text on any installed printer. On other systems a PostScript file is produced. This can be directly sent to a PostScript printer. For other printers a program like ghostscript needs to be used.

Note: If you have problems printing with `:hardcopy`, an alternative is to use `:TOhtml` and print the resulting html file from a browser.

`:ha` `:hardcopy` E237 E238 E324

`:[range]ha[rdcopy][!]` [*arguments*]

Send [*range*] lines (default whole file) to the printer.

On MS-Windows a dialog is displayed to allow selection of printer, paper size etc. To skip the dialog, use the `[!]`. In this case the printer defined by **'printdevice'** is used, or, if **'printdevice'** is empty, the system default printer.

For systems other than MS-Windows, PostScript is written in a temp file and **'printexpr'** is used to actually print it. Then [*arguments*] can be used by **'printexpr'** through `v:cmdarg`. Otherwise [*arguments*] is ignored. **'printoptions'** can be used to specify paper size, duplex, etc.

Note: If you want PDF, there are tools such as "ps2pdf" that can convert the PostScript to PDF.

`:[range]ha[rdcopy][!]` >{filename}

As above, but write the resulting PostScript in file {filename}.

Things like "%" are expanded `cmdline-special`

Careful: An existing file is silently overwritten.
{only available when compiled with the `+postscript`
feature}
On MS-Windows use the "print to file" feature of the
printer driver.

Progress is displayed during printing as a page number and a percentage. To
abort printing use the interrupt key (CTRL-C or, on MS-systems, **CTRL-Break**).

Printer output is controlled by the **'printfont'** and **'printoptions'** options.
'printhead' specifies the format of a page header.

The printed file is always limited to the selected margins, irrespective of
the current window's **'wrap'** or **'linebreak'** settings. The "wrap" item in
'printoptions' can be used to switch wrapping off.

The current highlighting colors are used in the printout, with the following
considerations:

- 1) The normal background is always rendered as white (i.e. blank paper).
- 2) White text or the default foreground is rendered as black, so that it shows
up!
- 3) If **'background'** is "dark", then the colours are darkened to compensate for
the fact that otherwise they would be too bright to show up clearly on
white paper.

2. Print options print-options

Here are the details for the options that change the way printing is done.
For generic info about setting options see [options.txt](#) .

'printdevice' **'pdev'** string (default empty) pdev-option
global
This defines the name of the printer to be used when the `:hardcopy` command
is issued with a bang (!) to skip the printer selection dialog. On Win32, it
should be the printer name exactly as it appears in the standard printer
dialog.
If the option is empty, then vim will use the system default printer for
":hardcopy!"

'printencoding' **'penc'** String (default empty, except for: penc-option E620
MS-Windows: cp1252,
Macintosh: mac-roman,
VMS: dec-mcs,
HPUX: hp-roman8,
EBCDIC: ebcdic-uk)
global

Sets the character encoding used when printing. This option tells Vim which
print character encoding file from the "print" directory in **'runtimepath'** to
use.

This option will accept any value from [encoding-names](#) . Any recognized names
are converted to Vim standard names - see **'encoding'** for more details. Names

not recognized by Vim will just be converted to lower case and underscores replaced with '-' signs.

If **'printencoding'** is empty or Vim cannot find the file then it will use **'encoding'** (if it is set an 8-bit encoding) to find the print character encoding file. If Vim is unable to find a character encoding file then it will use the "latin1" print character encoding file.

When **'encoding'** is set to a multibyte encoding, Vim will try to convert characters to the printing encoding for printing (if **'printencoding'** is empty then the conversion will be to latin1). Conversion to a printing encoding other than latin1 will require Vim to be compiled with the **+iconv** feature. If no conversion is possible then printing will fail. Any characters that cannot be converted will be replaced with upside down question marks.

Four print character encoding files are provided to support default Mac, VMS, HPUNIX, and EBCDIC character encodings and are used by default on these platforms. Code page 1252 print character encoding is used by default on MS-Windows platform.

'printexpr' 'pexpr' String (default: see below) pexpr-option
global

Expression that is evaluated to print the PostScript produced with **:hardcopy** .

The file name to be printed is in **v:fname_in** .

The arguments to the **:hardcopy** command are in **v:cmdarg** .

The expression must take care of deleting the file after printing it.

When there is an error, the expression must return a non-zero number.

If there is no error, return zero or an empty string.

The default for non MS-Windows or VMS systems is to simply use "lpr" to print the file:

```
system('lpr' .. (&printdevice == '' ? '' : '-P' .. &printdevice)
.. ' ' .. v:fname_in) .. delete(v:fname_in) + v:shell_error
```

On MS-Windows machines the default is to copy the file to the currently specified printdevice:

```
system('copy' .. ' ' .. v:fname_in .. (&printdevice == ''
? ' LPT1:' : (' \"' .. &printdevice .. '\"')))
.. delete(v:fname_in)
```

On VMS machines the default is to send the file to either the default or currently specified printdevice:

```
system('print' .. (&printdevice == '' ? '' : '/queue=' ..
&printdevice) .. ' ' .. v:fname_in) .. delete(v:fname_in)
```

If you change this option, using a function is an easy way to avoid having to escape all the spaces. Example:

```
:set printexpr=PrintFile()
:function PrintFile()
```

```

: call system("ghostview " .. v:fname_in)
: call delete(v:fname_in)
: return v:shell_error
:endifunc

```

It is more efficient if the option is set to just a function call, see [expr-option-function](#) .

Be aware that some print programs return control before they have read the file. If you delete the file too soon it will not be printed. These programs usually offer an option to have them remove the file when printing is done.

[E365](#)

If evaluating the expression fails or it results in a non-zero number, you get an error message. In that case Vim will delete the file. In the default value for non-MS-Windows a trick is used: Adding "v:shell_error" will result in a non-zero number when the system() call fails.

If the expression starts with s: or <SID> , then it is replaced with the script ID ([local-function](#)). Example:

```

set printexpr=s:MyPrintFile()
set printexpr=<SID>SomePrintFile()

```

Otherwise, the expression is evaluated in the context of the script where the option was set, thus script-local items are available.

This option cannot be set from a [modeline](#) or in the [sandbox](#) , for security reasons.

[pfn-option](#) [E613](#)

```

'printfont' 'pfn'      string (default "courier")
                        global

```

This is the name of the font that will be used for the [:hardcopy](#) command's output. It has the same format as the '[guifont](#)' option, except that only one font may be named, and the special "guifont=*" syntax is not available.

In the Win32 GUI version this specifies a font name with its extra attributes, as with the '[guifont](#)' option.

For other systems, only ":h11" is recognized, where "11" is the point size of the font. When omitted, the point size is 10.

[pheader-option](#)

```

'printhead' 'pheader' string (default "%<%f%h%m%=Page %N")
                        global

```

This defines the format of the header produced in [:hardcopy](#) output. The option is defined in the same way as the '[statusline](#)' option. If Vim has not been compiled with the [+statusline](#) feature, this option has no effect and a simple default header is used, which shows the page number. The same simple header is used when this option is empty.

[pmbcs-option](#)

```

'printmbcharset' 'pmbcs' string (default "")
                        global

```

Sets the CJK character set to be used when generating CJK output from [:hardcopy](#) . The following predefined values are currently recognised by Vim:

| | Value | Description |
|--------------------------|--------------|--|
| Chinese
(Simplified) | GB_2312-80 | |
| | GBT_12345-90 | |
| | MAC | Apple Mac Simplified Chinese |
| | GBT-90_MAC | GB/T 12345-90 Apple Mac Simplified Chinese |
| | GBK | GBK (GB 13000.1-93) |
| Chinese
(Traditional) | ISO10646 | ISO 10646-1:1993 |
| | CNS_1993 | CNS 11643-1993, Planes 1 & 2 |
| | BIG5 | |
| | ETEN | Big5 with ETen extensions |
| Japanese | ISO10646 | ISO 10646-1:1993 |
| | JIS_C_1978 | |
| | JIS_X_1983 | |
| | JIS_X_1990 | |
| | MSWINDOWS | Win3.1/95J (JIS X 1997 + NEC + IBM extensions) |
| | KANJITALK6 | Apple Mac KanjiTalk V6.x |
| Korean | KANJITALK7 | Apple Mac KanjiTalk V7.x |
| | KS_X_1992 | |
| | MAC | Apple Macintosh Korean |
| | MSWINDOWS | KS X 1992 with MS extensions |
| | ISO10646 | ISO 10646-1:1993 |

Only certain combinations of the above values and 'printencoding' are possible. The following tables show the valid combinations:

| | | eu-cn | gbk | ucs-2 | utf-8 |
|-------------------------|--------------|-------|-----|-------|-------|
| Chinese
(Simplified) | GB_2312-80 | x | | | |
| | GBT_12345-90 | x | | | |
| | MAC | x | | | |
| | GBT-90_MAC | x | | | |
| | GBK | | x | | |
| | ISO10646 | | | x | x |

| | | eu-tw | big5 | ucs-2 | utf-8 |
|--------------------------|----------|-------|------|-------|-------|
| Chinese
(Traditional) | CNS_1993 | x | | | |
| | BIG5 | | x | | |
| | ETEN | | x | | |
| | ISO10646 | | | x | x |

| | | eu-jp | sjis | ucs-2 | utf-8 |
|----------|------------|-------|------|-------|-------|
| Japanese | JIS_C_1978 | x | x | | |
| | JIS_X_1983 | x | x | | |
| | JIS_X_1990 | x | | x | x |
| | MSWINDOWS | | x | | |
| | KANJITALK6 | | x | | |
| | KANJITALK7 | | x | | |

| | | eu-kr | cp949 | ucs-2 | utf-8 |
|--|--|-------|-------|-------|-------|
|--|--|-------|-------|-------|-------|

| | | | | | |
|--------|-----------|---|---|---|---|
| Korean | KS_X_1992 | x | | | |
| | MAC | x | | | |
| | MSWINDOWS | | x | | |
| | ISO10646 | | | x | x |

To set up the correct encoding and character set for printing some Japanese text you would do the following;

```
:set printencoding=euc-jp
:set printmbcharset=JIS_X_1983
```

If **'printmbcharset'** is not one of the above values then it is assumed to specify a custom multibyte character set and no check will be made that it is compatible with the value for **'printencoding'**. Vim will look for a file defining the character set in the "print" directory in **'runtimepath'**.

pmbfn-option

'printmbfont' **'pmbfn'** string (default "")
global

This is a comma-separated list of fields for font names to be used when generating CJK output from **:hardcopy**. Each font name has to be preceded with a letter indicating the style the font is to be used for as follows:

```
r:{font-name}      font to use for normal characters
b:{font-name}      font to use for bold characters
i:{font-name}      font to use for italic characters
o:{font-name}      font to use for bold-italic characters
```

A field with the r: prefix must be specified when doing CJK printing. The other fontname specifiers are optional. If a specifier is missing then another font will be used as follows:

```
if b: is missing, then use r:
if i: is missing, then use r:
if o: is missing, then use b:
```

Some CJK fonts do not contain characters for codes in the ASCII code range. Also, some characters in the CJK ASCII code ranges differ in a few code points from traditional ASCII characters. There are two additional fields to control printing of characters in the ASCII code range.

```
c:yes              Use Courier font for characters in the ASCII
c:no (default)     code range.

a:yes              Use ASCII character set for codes in the ASCII
a:no (default)     code range.
```

The following is an example of specifying two multibyte fonts, one for normal and italic printing and one for bold and bold-italic printing, and using Courier to print codes in the ASCII code range but using the national character set:

```
:set printmbfont=r:WadaMin-Regular,b:WadaMin-Bold,c:yes
```

popt-option

'printoptions' **'popt'** string (default "")

global

This is a comma-separated list of items that control the format of the output of `:hardcopy` :

| | |
|------------------------------------|---|
| <code>left:{spec}</code> | left margin (default: 10pc) |
| <code>right:{spec}</code> | right margin (default: 5pc) |
| <code>top:{spec}</code> | top margin (default: 5pc) |
| <code>bottom:{spec}</code> | bottom margin (default: 5pc) |
| | <code>{spec}</code> is a number followed by "in" for inches, "pt" for points (1 point is 1/72 of an inch), "mm" for millimeters or "pc" for a percentage of the media size. |
| | Weird example:
<code>left:2in,top:30pt,right:16mm,bottom:3pc</code> |
| | If the unit is not recognized there is no error and the default value is used. |
| <code>header:{nr}</code> | Number of lines to reserve for the header.
Only the first line is actually filled, thus when <code>{nr}</code> is 2 there is one empty line. The header is formatted according to ' <code>printhheader</code> '. |
| <code>header:0</code> | Do not print a header. |
| <code>header:2 (default)</code> | Use two lines for the header |
| <code>syntax:n</code> | Do not use syntax highlighting. This is faster and thus useful when printing large files. |
| <code>syntax:y</code> | Do syntax highlighting. |
| <code>syntax:a (default)</code> | Use syntax highlighting if the printer appears to be able to print color or grey. |
| <code>number:y</code> | Include line numbers in the printed output. |
| <code>number:n (default)</code> | No line numbers. |
| <code>wrap:y (default)</code> | Wrap long lines. |
| <code>wrap:n</code> | Truncate long lines. |
| <code>duplex:off</code> | Print on one side. |
| <code>duplex:long (default)</code> | Print on both sides (when possible), bind on long side. |
| <code>duplex:short</code> | Print on both sides (when possible), bind on short side. |
| <code>collate:y (default)</code> | Collating: 1 2 3, 1 2 3, 1 2 3 |
| <code>collate:n</code> | No collating: 1 1 1, 2 2 2, 3 3 3 |
| <code>jobsplit:n (default)</code> | Do all copies in one print job |
| <code>jobsplit:y</code> | Do each copy as a separate print job. Useful when doing N-up postprocessing. |
| <code>portrait:y (default)</code> | Orientation is portrait. |
| <code>portrait:n</code> | Orientation is landscape. |
| <code>paper:A4 (default)</code> | Paper size: A4 |
| <code>paper:{name}</code> | Paper size from this table: |

a4 letter

| {name} | size in cm | size in inch |
|-----------|---------------|---------------|
| 10x14 | 25.4 x 35.57 | 10 x 14 |
| A3 | 29.7 x 42 | 11.69 x 16.54 |
| A4 | 21 x 29.7 | 8.27 x 11.69 |
| A5 | 14.8 x 21 | 5.83 x 8.27 |
| B4 | 25 x 35.3 | 10.12 x 14.33 |
| B5 | 17.6 x 25 | 7.17 x 10.12 |
| executive | 18.42 x 26.67 | 7.25 x 10.5 |
| folio | 21 x 33 | 8.27 x 13 |
| ledger | 43.13 x 27.96 | 17 x 11 |
| legal | 21.59 x 35.57 | 8.5 x 14 |
| letter | 21.59 x 27.96 | 8.5 x 11 |
| quarto | 21.59 x 27.5 | 8.5 x 10.83 |
| statement | 13.97 x 21.59 | 5.5 x 8.5 |
| tabloid | 27.96 x 43.13 | 11 x 17 |

- formfeed:n (default) Treat form feed characters (0x0c) as a normal print character.
- formfeed:y When a form feed character is encountered, continue printing of the current line at the beginning of the first line on a new page.

The item indicated with (default) is used when the item is not present. The values are not always used, especially when using a dialog to select the printer and options.

Example:

```
:set printoptions=paper:letter,duplex:off
```

3. PostScript Printing

postscript-printing
E455 E456 E457 E624

Provided you have enough disk space there should be no problems generating a PostScript file. You need to have the runtime files correctly installed (if you can find the help files, they probably are).

There are currently a number of limitations with PostScript printing:

- **'printfont'** - The font name is ignored (the Courier family is always used - it should be available on all PostScript printers) but the font size is used.
- **'printoptions'** - The duplex setting is used when generating PostScript output, but it is up to the printer to take notice of the setting. If the printer does not support duplex printing then it should be silently ignored. Some printers, however, don't print at all.
- 8-bit support - While a number of 8-bit print character encodings are supported it is possible that some characters will not print. Whether a character will print depends on the font in the printer knowing the character. Missing characters will be replaced with an upside down question mark, or a space if that character is also not known by the font. It may be possible to get all the characters in an encoding to print by installing a new version of the Courier font family.

- Multi-byte support - Currently Vim will try to convert multibyte characters to the 8-bit encoding specified by **'printencoding'** (or latin1 if it is empty). Any characters that are not successfully converted are shown as unknown characters. Printing will fail if Vim cannot convert the multibyte to the 8-bit encoding.

4. Custom 8-bit Print Character Encodings postscript-print-encoding E618 E619

To use your own print character encoding when printing 8-bit character data you need to define your own PostScript font encoding vector. Details on how to define a font encoding vector is beyond the scope of this help file, but you can find details in the PostScript Language Reference Manual, 3rd Edition, published by Addison-Wesley and available in PDF form at <http://www.adobe.com/>. The following describes what you need to do for Vim to locate and use your print character encoding.

- Decide on a unique name for your encoding vector, one that does not clash with any of the recognized or standard encoding names that Vim uses (see [encoding-names](#) for a list), and that no one else is likely to use.
- Copy \$VIMRUNTIME/print/latin1.ps to the print subdirectory in your **'runtimepath'** and rename it with your unique name.
- Edit your renamed copy of latin1.ps, replacing all occurrences of latin1 with your unique name (don't forget the line starting %%Title:), and modify the array of glyph names to define your new encoding vector. The array must have exactly 256 entries or you will not be able to print!
- Within Vim, set **'printencoding'** to your unique encoding name and then print your file. Vim will now use your custom print character encoding.

Vim will report an error with the resource file if you change the order or content of the first 3 lines, other than the name of the encoding on the line starting %%Title: or the version number on the line starting %%Version:.

[Technical explanation for those that know PostScript - Vim looks for a file with the same name as the encoding it will use when printing. The file defines a new PostScript Encoding resource called /VIM-name, where name is the print character encoding Vim will use.]

5. PostScript CJK Printing postscript-cjk-printing E673 E674 E675

Vim supports printing of Chinese, Japanese, and Korean files. Setting up Vim to correctly print CJK files requires setting up a few more options.

Each of these countries has many standard character sets and encodings which require that both be specified when printing. In addition, CJK fonts normally do not have the concept of italic glyphs and use different weight or stroke style to achieve emphasis when printing. This in turn requires a different approach to specifying fonts to use when printing.

The encoding and character set are specified with the **'printencoding'** and **'printmbcharset'** options. If **'printencoding'** is not specified then **'encoding'** is used as normal. If **'printencoding'** is specified then characters will be

translated to this encoding for printing. You should ensure that the encoding is compatible with the character set needed for the file contents or some characters may not appear when printed.

The fonts to use for CJK printing are specified with `'printmbfont'`. This option allows you to specify different fonts to use when printing characters which are syntax highlighted with the font styles normal, italic, bold and bold-italic.

No CJK fonts are supplied with Vim. There are some free Korean, Japanese, and Traditional Chinese fonts available at:

<http://examples.oreilly.com/cjkvinfo/adobe/samples/>
<https://resources.oreilly.com/examples/9781565922242/>

You can find descriptions of the various fonts in the read me file at

<https://resources.oreilly.com/examples/9781565922242/-/blob/master/00README>

Please read your printer documentation on how to install new fonts.

CJK fonts can be large containing several thousand glyphs, and it is not uncommon to find that they only contain a subset of a national standard. It is not unusual to find the fonts to not include characters for codes in the ASCII code range. If you find half-width Roman characters are not appearing in your printout then you should configure Vim to use the Courier font the half-width ASCII characters with `'printmbfont'`. If your font does not include other characters then you will need to find another font that does.

Another issue with ASCII characters, is that the various national character sets specify a couple of different glyphs in the ASCII code range. If you print ASCII text using the national character set you may see some unexpected characters. If you want true ASCII code printing then you need to configure Vim to output ASCII characters for the ASCII code range with `'printmbfont'`.

It is possible to define your own multibyte character set although this should not be attempted lightly. A discussion on the process is beyond the scope of these help files. You can find details on CMap (character map) files in the document 'Adobe CMap and CIDFont Files Specification, Version 1.0', available from <http://www.adobe.com> as a PDF file.

=====

6. PostScript Printing Troubleshooting `postscript-print-trouble` E621

Usually the only sign of a problem when printing with PostScript is that your printout does not appear. If you are lucky you may get a printed page that tells you the PostScript operator that generated the error that prevented the print job completing.

There are a number of possible causes as to why the printing may have failed:

- Wrong version of the prolog resource file. The prolog resource file contains some PostScript that Vim needs to be able to print. Each version of Vim needs one particular version. Make sure you have correctly installed

the runtime files, and don't have any old versions of a file called prolog in the print directory in your `'runtimepath'` directory.

- Paper size. Some PostScript printers will abort printing a file if they do not support the requested paper size. By default Vim uses A4 paper. Find out what size paper your printer normally uses and set the appropriate paper size with `'printoptions'`. If you cannot find the name of the paper used, measure a sheet and compare it with the table of supported paper sizes listed for `'printoptions'`, using the paper that is closest in both width AND height. **Note:** The dimensions of actual paper may vary slightly from the ones listed. If there is no paper listed close enough, then you may want to try `psresize` from PSUtils, discussed below.
- Two-sided printing (duplex). Normally a PostScript printer that does not support two-sided printing will ignore any request to do it. However, some printers may abort the job altogether. Try printing with duplex turned off. **Note:** Duplex prints can be achieved manually using PS utils - see below.
- Collated printing. As with Duplex printing, most PostScript printers that do not support collating printouts will ignore a request to do so. Some may not. Try printing with collation turned off.
- Syntax highlighting. Some print management code may prevent the generated PostScript file from being printed on a black and white printer when syntax highlighting is turned on, even if solid black is the only color used. Try printing with syntax highlighting turned off.

A safe `printoptions` setting to try is:

```
:set printoptions=paper:A4,duplex:off,collate:n,syntax:n
```

Replace "A4" with the paper size that best matches your printer paper.

7. PostScript Utilities postscript-print-util

7.1 Ghostscript

Ghostscript is a PostScript and PDF interpreter that can be used to display and print on non-PostScript printers PostScript and PDF files. It can also generate PDF files from PostScript.

Ghostscript will run on a wide variety of platforms.

There are three available versions:

- AFPL Ghostscript (formerly Aladdin Ghostscript) which is free for non-commercial use. It can be obtained from:

<http://www.cs.wisc.edu/~ghost/>

- GNU Ghostscript which is available under the GNU General Public License. It can be obtained from:

<https://www.gnu.org/software/ghostscript>

- A commercial version for inclusion in commercial products.

Additional information on Ghostscript can also be found at:

<http://www.ghostscript.com/>

Support for a number of non PostScript printers is provided in the distribution as standard, but if you cannot find support for your printer check the Ghostscript site for other printers not included by default.

7.2 Ghostscript Previewers.

The interface to Ghostscript is very primitive so a number of graphical front ends have been created. These allow easier PostScript file selection, previewing at different zoom levels, and printing. Check supplied documentation for full details.

X11

- Ghostview. Obtainable from:

<http://www.cs.wisc.edu/~ghost/gv/>
<https://www.gnu.org/software/gv/>

Copies (possibly not the most recent) can be found at:

<http://www.cs.wisc.edu/~ghost/gv/>

OpenVMS

- Is apparently supported in the main code now (untested).
See (link seems dead):

<http://wwwthep.physik.uni-mainz.de/~plass/gv/>

MS-Windows

- GSview. Obtainable from:

<http://www.cs.wisc.edu/~ghost/gsview/>

Linux

- GSview. Linux version of the popular MS-Windows previewer.
Obtainable from:

<http://www.cs.wisc.edu/~ghost/gsview/>

7.3 PSUtils

PSUtils is a collection of utility programs for manipulating PostScript

documents. Binary distributions are available for many platforms, as well as the full source. PSUtils can be found at:

<http://knackered.org/angus/psutils>

The utilities of interest include:

- psnup. Convert PS files for N-up printing.
- psselect. Select page range and order of printing.
- psresize. Change the page size.
- psbook. Reorder and lay out pages ready for making a book.

The output of one program can be used as the input to the next, allowing for complex print document creation.

N-UP PRINTING

The psnup utility takes an existing PostScript file generated from Vim and convert it to an n-up version. The simplest way to create a 2-up printout is to first create a PostScript file with:

```
:hardcopy > test.ps
```

Then on your command line execute:

```
psnup -n 2 test.ps final.ps
```

Note: You may get warnings from some Ghostscript previewers for files produced by psnup - these may safely be ignored.

Finally print the file final.ps to your PostScript printer with your platform's print command. (You will need to delete the two PostScript files afterwards yourself.) **'printexpr'** could be modified to perform this extra step before printing.

ALTERNATE DUPLEX PRINTING

It is possible to achieve a poor man's version of duplex printing using the PS utility psselect. This utility has options -e and -o for printing just the even or odd pages of a PS file respectively.

First generate a PS file with the **'hardcopy'** command, then generate new files with all the odd and even numbered pages with:

```
psselect -o test.ps odd.ps  
psselect -e test.ps even.ps
```

Next print odd.ps with your platform's normal print command. Then take the print output, turn it over and place it back in the paper feeder. Now print even.ps with your platform's print command. All the even pages should now appear on the back of the odd pages.

There are a couple of points to bear in mind:

1. Position of the first page. If the first page is on top of the printout when printing the odd pages then you need to reverse the order that the odd pages are printed. This can be done with the `-r` option to `psselect`. This will ensure page 2 is printed on the back of page 1.
Note: it is better to reverse the odd numbered pages rather than the even numbered in case there are an odd number of pages in the original PS file.
2. Paper flipping. When turning over the paper with the odd pages printed on them you may have to either flip them horizontally (along the long edge) or vertically (along the short edge), as well as possibly rotating them 180 degrees. All this depends on the printer - it will be more obvious for desktop ink jets than for small office laser printers where the paper path is hidden from view.

8. Formfeed Characters

printing-formfeed

By default Vim does not do any special processing of formfeed control characters. Setting the `'printoptions'` formfeed item will make Vim recognize formfeed characters and continue printing the current line at the beginning of the first line on a new page. The use of formfeed characters provides rudimentary print control but there are certain things to be aware of.

Vim will always start printing a line (including a line number if enabled) containing a formfeed character, even if it is the first character on the line. This means if a line starting with a formfeed character is the first line of a page then Vim will print a blank page.

Since the line number is printed at the start of printing the line containing the formfeed character, the remainder of the line printed on the new page will not have a line number printed for it (in the same way as the wrapped lines of a long line when wrap in `'printoptions'` is enabled).

If the formfeed character is the last character on a line, then printing will continue on the second line of the new page, not the first. This is due to Vim processing the end of the line after the formfeed character and moving down a line to continue printing.

Due to the points made above it is recommended that when formfeed character processing is enabled, printing of line numbers is disabled, and that form feed characters are not the last character on a line. Even then you may need to adjust the number of lines before a formfeed character to prevent accidental blank pages.

Vim client-server communication

client-server

- 1. Common functionality `clientserver`
- 2. X11 specific items `x11-clientserver`
- 3. MS-Windows specific items `w32-clientserver`

1. Common functionality

clientserver

When compiled with the `+clientserver` option, Vim can act as a command server. It accepts messages from a client and executes them. At the same time, Vim can function as a client and send commands to a Vim server.

The following command line arguments are available:

| argument | meaning |
|---|---|
| <code>--remote [+{cmd}] {file} ...</code> | <code>--remote</code>
Open the file list in a remote Vim. When there is no Vim server, execute locally. There is one optional init command: <code>+{cmd}</code> . This must be an Ex command that can be followed by <code> </code> . The rest of the command line is taken as the file list. Thus any non-file arguments must come before this. You cannot edit stdin this way <code>--</code> . The remote Vim is raised. If you don't want this use
<code>vim --remote-send "<C-\><C-N>:n filename<CR>"</code> |
| <code>--remote-silent [+{cmd}] {file} ...</code> | <code>--remote-silent</code>
As above, but don't complain if there is no server and the file is edited locally. |
| <code>--remote-wait [+{cmd}] {file} ...</code> | <code>--remote-wait</code>
As <code>--remote</code> , but wait for files to complete (unload) in remote Vim. |
| <code>--remote-wait-silent [+{cmd}] {file} ...</code> | <code>--remote-wait-silent</code>
As <code>--remote-wait</code> , but don't complain if there is no server. |
| <code>--remote-tab</code> | <code>--remote-tab</code>
Like <code>--remote</code> but open each file in a new tabpage. |
| <code>--remote-tab-silent</code> | <code>--remote-tab-silent</code>
Like <code>--remote-silent</code> but open each file in a new tabpage. |
| <code>--remote-tab-wait</code> | <code>--remote-tab-wait</code>
Like <code>--remote-wait</code> but open each file in a new |

tabpage.

| | | |
|---------------------------------------|---|---------------------------------------|
| | | <code>--remote-tab-wait-silent</code> |
| <code>--remote-tab-wait-silent</code> | Like <code>--remote-wait-silent</code> but open each file in a new tabpage. | |
| | | <code>--servername</code> |
| <code>--servername {name}</code> | Become the server <code>{name}</code> . When used together with one of the <code>--remote</code> commands: connect to server <code>{name}</code> instead of the default (see below). The name used will be uppercase. | |
| | | <code>--remote-send</code> |
| <code>--remote-send {keys}</code> | Send <code>{keys}</code> to server and exit. The <code>{keys}</code> are not mapped. Special key names are recognized, e.g., " <code><CR></code> " results in a CR character. | |
| | | <code>--remote-expr</code> |
| <code>--remote-expr {expr}</code> | Evaluate <code>{expr}</code> in server and print the result on stdout. | |
| | | <code>--serverlist</code> |
| <code>--serverlist</code> | Output a list of server names. | |

Examples

Edit "file.txt" in an already running GVIM server:

```
gvim --remote file.txt
```

Edit "file.txt" in an already running server called FOOBAR:

```
gvim --servername FOOBAR --remote file.txt
```

Edit "file.txt" in server "FILES" if it exists, become server "FILES" otherwise:

```
gvim --servername FILES --remote-silent file.txt
```

This doesn't work, all arguments after `--remote` will be used as file names:

```
gvim --remote --servername FOOBAR file.txt
```

Edit file "+foo" in a remote server (note the use of "./" to avoid the special meaning of the leading plus):

```
vim --remote ./+foo
```

Tell the remote server "BLA" to write all files and exit:

```
vim --servername BLA --remote-send '<C-\><C-N>:wqa<CR>'
```

SERVER NAME

`client-server-name`

By default Vim will try to register the name under which it was invoked (`gvim`, `gvim ...`). This can be overridden with the `--servername` argument. If the specified name is not available, a postfix is applied until a free name is encountered, i.e. "gvim1" for the second invocation of `gvim` on a particular X-server. The resulting name is available in the `servername` builtin variable `v:servername`. The case of the server name is ignored, thus "gvim" and "GVIM" are considered equal.

When Vim is invoked with `--remote`, `--remote-wait` or `--remote-send` it will try to locate the server name determined by the invocation name and `--servername` argument as described above. If an exact match is not available, the first server with the number postfix will be used. If a name with the number postfix is specified with the `--servername` argument, it must match exactly.

If no server can be located and `--remote` or `--remote-wait` was used, Vim will start up according to the rest of the command line and do the editing by itself. This way it is not necessary to know whether `gvim` is already started when sending command to it.

The `--serverlist` argument will cause Vim to print a list of registered command servers on the standard output (stdout) and exit.

The `{server}` argument is used by several functions. When this is an empty string then on Unix the default server name is used, which is "GVIM". On MS-Windows an empty string does not work.

Win32 **Note:** Making the Vim server go to the foreground doesn't always work, because MS-Windows doesn't allow it. The client will move the server to the foreground when using the `--remote` or `--remote-wait` argument and the server name starts with "g".

REMOTE EDITING

The `--remote` argument will cause a `:drop` command to be constructed from the rest of the command line and sent as described above.

The `--remote-wait` argument does the same thing and additionally sets up to wait for each of the files to have been edited. This uses the `BufUnload` event, thus as soon as a file has been unloaded, Vim assumes you are done editing it.

Note that the `--remote` and `--remote-wait` arguments will consume the rest of the command line. I.e. all remaining arguments will be regarded as filenames. You can not put options there!

FUNCTIONS

There are a number of Vim functions for scripting the command server. See the description in `builtin.txt` or use **CTRL-]** on the function name to jump to the full explanation.

synopsis

```
remote_startserver( name)
remote_expr( server, string, idvar)
remote_send( server, string, idvar)
serverlist()
remote_peek( serverid, retvar)
remote_read( serverid)
server2client( serverid, string)
remote_foreground( server)
```

explanation

```
run a server
send expression
send key sequence
get a list of available servers
check for reply string
read reply string
send reply string
bring server to the front
```

See also the explanation of `CTRL-_CTRL-N` . Very useful as a leading key sequence.

The `{serverid}` for `server2client()` can be obtained with `expand("<client>")`

2. X11 specific items

`x11-clientserver`

`E247` `E248` `E251` `E258` `E277`

The communication between client and server goes through the X server. The display of the Vim server must be specified. The usual protection of the X server is used, you must be able to open a window on the X server for the communication to work. It is possible to communicate between different systems.

By default, a GUI Vim will register a name on the X-server by which it can be addressed for subsequent execution of injected strings. Vim can also act as a client and send strings to other instances of Vim on the same X11 display.

When an X11 GUI Vim (`gvim`) is started, it will try to register a send-server name on the 'VimRegistry' property on the root window.

A non GUI Vim with access to the X11 display (`xterm-clipboard` enabled), can also act as a command server if a server name is explicitly given with the `--servername` argument, or when Vim was built with the `+autoservername` feature.

An empty `--servername` argument will cause the command server to be disabled.

To send commands to a Vim server from another application, read the source file `src/if_xcmdsrv.c`, it contains some hints about the protocol used.

3. Win32 specific items

`w32-clientserver`

Every Win32 Vim can work as a server, also in the console. You do not need a version compiled with OLE. Windows messages are used, this works on any version of MS-Windows. But only communication within one system is possible.

Since MS-Windows messages are used, any other application should be able to communicate with a Vim server. An alternative is using the OLE functionality `ole-interface` .

When using `gvim`, the `--remote-wait` only works properly this way:

```
start /w gvim --remote-wait file.txt
```

Terminal information

[terminal-info](#)

Vim uses information about the terminal you are using to fill the screen and recognize what keys you hit. If this information is not correct, the screen may be messed up or keys may not be recognized. The actions which have to be performed on the screen are accomplished by outputting a string of characters. Special keys produce a string of characters. These strings are stored in the terminal options, see [terminal-options](#) .

NOTE: Most of this is not used when running the [GUI](#) .

- | | |
|----------------------------|------------------------------------|
| 1. Startup | startup-terminal |
| 2. Terminal options | terminal-options |
| 3. Window size | window-size |
| 4. Slow and fast terminals | slow-fast-terminal |
| 5. Using the mouse | mouse-using |

=====

1. Startup

[startup-terminal](#)

When Vim is started a default terminal type is assumed. For the Amiga this is a standard CLI window, for MS-Windows the pc terminal, for Unix an ansi terminal. A few other terminal types are always available, see below [builtin-terms](#) .

You can give the terminal name with the '-T' Vim argument. If it is not given Vim will try to get the name from the TERM environment variable.

[termcap](#) [terminfo](#) [E557](#) [E558](#) [E559](#)

On Unix the terminfo database or termcap file is used. This is referred to as "termcap" in all the documentation. At compile time, when running configure, the choice whether to use terminfo or termcap is done automatically. When running Vim the output of ":version" will show [+terminfo](#) if terminfo is used. Also see [xterm-screens](#) .

On non-Unix systems a termcap is only available if Vim was compiled with TERMCAP defined.

[builtin-terms](#) [builtin_terms](#)

A number of builtin terminals are available. Since patch 9.0.0280 there is no difference between Vim versions. You can see a list of available builtin terminals in the error message you get for `:set term=xxx` (when not running the GUI). Also see [++builtin_terms](#) .

If the termcap code is included Vim will try to get the strings for the terminal you are using from the termcap file and the builtin termcaps. Both are always used, if an entry for the terminal you are using is present. Which one is used first depends on the ['ttybuiltin'](#) option:

| | | |
|-------------------------------|---------------------|---------------------|
| <code>'ttybuiltin'</code> on | 1: builtin termcap | 2: external termcap |
| <code>'ttybuiltin'</code> off | 1: external termcap | 2: builtin termcap |

If an option is missing in one of them, it will be obtained from the other one. If an option is present in both, the one first encountered is used.

Which external termcap file is used varies from system to system and may depend on the environment variables "TERMCAP" and "TERMPATH". See "man tgetent".

Settings depending on terminal

[term-dependent-settings](#)

If you want to set options or mappings, depending on the terminal name, you can do this best in your .vimrc. Example:

```
if &term == "xterm"
  ... xterm maps and settings ...
elseif &term =~ "vt10."
  ... vt100, vt102 maps and settings ...
endif
```

[raw-terminal-mode](#)

For normal editing the terminal will be put into "raw" mode. The strings defined with `'t_ti'`, `'t_TI'` and `'t_ks'` will be sent to the terminal. Normally this puts the terminal in a state where the termcap codes are valid and activates the cursor and function keys.

When Vim exits the terminal will be put back into the mode it was before Vim started. The strings defined with `'t_te'`, `'t_TE'` and `'t_ke'` will be sent to the terminal. On the Amiga, with commands that execute an external command (e.g., "!!"), the terminal will be put into Normal mode for a moment. This means that you can stop the output to the screen by hitting a printing key. Output resumes when you hit `<BS>`.

Note: When `'t_ti'` is not empty, Vim assumes that it causes switching to the alternate screen. This may slightly change what happens when executing a shell command or exiting Vim. To avoid this use `'t_TI'` and `'t_TE'` (but make sure to add to them, not overwrite).

Vim will try to detect what keyboard protocol the terminal is using with the `'t_RK'` termcap entry. This is sent after `'t_TI'`, but only when there is no work to do (no typeahead and no pending commands). That is to avoid the response to end up in a shell command or arrive after Vim exits.

[xterm-bracketed-paste](#)

When the `'t_BE'` option is set then `'t_BE'` will be sent to the terminal when entering "raw" mode and `'t_BD'` when leaving "raw" mode. The terminal is then expected to put `'t_PS'` before pasted text and `'t_PE'` after pasted text. This way Vim can separate text that is pasted from characters that are typed. The pasted text is handled like when the middle mouse button is used, it is inserted literally and not interpreted as commands.

Please **note:** while bracketed paste is trying to prevent nasty side-effects from pasting (like the `CTRL-C` or `<ESC>` key), it's not a guaranteed security

measure because different terminals may implement this mode slightly differently. You should still be careful with what you paste into Vim.

When the cursor is in the first column, the pasted text will be inserted before it. Otherwise the pasted text is appended after the cursor position. This means one cannot paste after the first column. Unfortunately Vim does not have a way to tell where the mouse pointer was.

Note that in some situations Vim will not recognize the bracketed paste and you will get the raw text. In other situations Vim will only get the first pasted character and drop the rest, e.g. when using the "r" command. If you have a problem with this, disable bracketed paste by putting this in your .vimrc:

```
set t_BE=
```

If this is done while Vim is running the '**t_BD**' will be sent to the terminal to disable bracketed paste.

If **t_PS** or **t_PE** is not set, then **t_BE** will not be used. This is to make sure that bracketed paste is not enabled when the escape codes surrounding pasted text cannot be recognized.

Note: bracketed paste mode will be disabled, when the '**esckey**s' option is not set (also when the '**compatible**' option is set).

If your terminal supports bracketed paste, but the options are not set automatically, you can try using something like this:

```
if &term =~ "screen"
  let &t_BE = "\e[?2004h"
  let &t_BD = "\e[?2004l"
  exec "set t_PS=\e[200~"
  exec "set t_PE=\e[201~"
endif
```

The terminfo entries "BE", "BD", "PS" and "PE" were added in ncurses version 6.4, early 2023, for some terminals. If you have this version then you may not have to manually configure your terminal.

tmux-integration

If you experience issues when running Vim inside tmux, here are a few hints. You can comment-out parts if something doesn't work (it may depend on the terminal that tmux is running in):

```
if !has('gui_running') && &term =~ '^\(screen\|tmux\)'
  " Better mouse support, see :help 'ttymouse'
  set ttymouse=sgr

  " Enable true colors, see :help xterm-true-color
  let &termguicolors = v:true
  let &t_8f = "\<Esc>[38;2;%lu;%lu;%lum"
  let &t_8b = "\<Esc>[48;2;%lu;%lu;%lum"

  " Enable bracketed paste mode, see :help xterm-bracketed-paste
  let &t_BE = "\<Esc>[?2004h"
```

```

let &t_BD = "\<Esc>[?2004]"
let &t_PS = "\<Esc>[200~"
let &t_PE = "\<Esc>[201~"

" Enable focus event tracking, see :help xterm-focus-event
let &t_fe = "\<Esc>[?1004h"
let &t_fd = "\<Esc>[?1004l"
execute "set <FocusGained>=\<Esc>[I"
execute "set <FocusLost>=\<Esc>[O"

" Enable modified arrow keys, see :help arrow_modifiers
execute "silent! set <xUp>=\<Esc>[O;*A"
execute "silent! set <xDown>=\<Esc>[O;*B"
execute "silent! set <xRight>=\<Esc>[O;*C"
execute "silent! set <xLeft>=\<Esc>[O;*D"
endif

```

cs7-problem

Note: If the terminal settings are changed after running Vim, you might have an illegal combination of settings. This has been reported on Solaris 2.5 with "stty cs8 parenb", which is restored as "stty cs7 parenb". Use "stty cs8 -parenb -istrip" instead, this is restored correctly.

Some termcap entries are wrong in the sense that after sending '**t_ks**' the cursor keys send codes different from the codes defined in the termcap. To avoid this you can set '**t_ks**' (and '**t_ke**') to empty strings. This must be done during initialization (see [initialization](#)), otherwise it's too late.

Some termcap entries assume that the highest bit is always reset. For example: The cursor-up entry for the Amiga could be ":ku=\E[A:". But the Amiga really sends "\233A". This works fine if the highest bit is reset, e.g., when using an Amiga over a serial line. If the cursor keys don't work, try the entry ":ku=\233A:".

Some termcap entries have the entry ":ku=\E[A:". But the Amiga really sends "\233A". On output "\E[" and "\233" are often equivalent, on input they aren't. You will have to change the termcap entry, or change the key code with the :set command to fix this.

Many cursor key codes start with an **<Esc>**. Vim must find out if this is a single hit of the **<Esc>** key or the start of a cursor key sequence. It waits for a next character to arrive. If it does not arrive within one second a single **<Esc>** is assumed. On very slow systems this may fail, causing cursor keys not to work sometimes. If you discover this problem reset the '**timeout**' option. Vim will wait for the next character to arrive after an **<Esc>**. If you want to enter a single **<Esc>** you must type it twice. Resetting the '**esckey**' option avoids this problem in Insert mode, but you lose the possibility to use cursor and function keys in Insert mode.

On the Amiga the recognition of window resizing is activated only when the terminal name is "amiga" or "builtin_amiga".

Some terminals have confusing codes for the cursor keys. The televideo 925 is such a terminal. It sends a **CTRL-H** for cursor-left. This would make it

impossible to distinguish a backspace and cursor-left. To avoid this problem **CTRL-H** is never recognized as cursor-left.

vt100-cursor-keys xterm-cursor-keys

Other terminals (e.g., vt100 and xterm) have cursor keys that send `<Esc>OA`, `<Esc>OB`, etc. Unfortunately these are valid commands in insert mode: Stop insert, Open a new line above the new one, start inserting 'A', 'B', etc. Instead of performing these commands Vim will erroneously recognize this typed key sequence as a cursor key movement. To avoid this and make Vim do what you want in either case you could use these settings:

```
:set notimeout      " don't timeout on mappings
:set ttimeout       " do timeout on terminal key codes
:set timeoutlen=100 " timeout after 100 msec
```

This requires the key-codes to be sent within 100 msec in order to recognize them as a cursor key. When you type you normally are not that fast, so they are recognized as individual typed commands, even though Vim receives the same sequence of bytes.

vt100-function-keys xterm-function-keys

An xterm can send function keys F1 to F4 in two modes: vt100 compatible or not. Because Vim may not know what the xterm is sending, both types of keys are recognized. The same happens for the `<Home>` and `<End>` keys.

| | | normal | | vt100 | |
|---------------------------|-------------------|------------------------------|----------------------------|----------------------------|----------------------------------|
| <code><F1></code> | <code>t_k1</code> | <code><Esc>[11~</code> | <code><xF1></code> | <code><Esc>OP</code> | <code><xF1>-xterm</code> |
| <code><F2></code> | <code>t_k2</code> | <code><Esc>[12~</code> | <code><xF2></code> | <code><Esc>OQ</code> | <code><xF2>-xterm</code> |
| <code><F3></code> | <code>t_k3</code> | <code><Esc>[13~</code> | <code><xF3></code> | <code><Esc>OR</code> | <code><xF3>-xterm</code> |
| <code><F4></code> | <code>t_k4</code> | <code><Esc>[14~</code> | <code><xF4></code> | <code><Esc>OS</code> | <code><xF4>-xterm</code> |
| <code><Home></code> | <code>t_kh</code> | <code><Esc>[7~</code> | <code><xHome></code> | <code><Esc>OH</code> | <code><xHome>-xterm</code> |
| <code><End></code> | <code>t_@7</code> | <code><Esc>[4~</code> | <code><xEnd></code> | <code><Esc>OF</code> | <code><xEnd>-xterm</code> |

When Vim starts, `<xF1>` is mapped to `<F1>`, `<xF2>` to `<F2>` etc. This means that by default both codes do the same thing. If you make a mapping for `<xF2>`, because your terminal does have two keys, the default mapping is overwritten, thus you can use the `<F2>` and `<xF2>` keys for something different.

xterm-shifted-keys

Newer versions of xterm support shifted function keys and special keys. Vim recognizes most of them. Use `":set termcap"` to check which are supported and what the codes are. Mostly these are not in a termcap, they are only supported by the builtin_xterm termcap.

xterm-modifier-keys

Newer versions of xterm support Alt and Ctrl for most function keys. To avoid having to add all combinations of Alt, Ctrl and Shift for every key a special sequence is recognized at the end of a termcap entry: `";*X"`. The "X" can be any character, often `'~'` is used. The `";*"` stands for an optional modifier argument. `";2"` is Shift, `";3"` is Alt, `";5"` is Ctrl and `";9"` is Meta (when it's different from Alt). They can be combined. Examples:

```
:set <F8>=^[[19;*~
:set <Home>=^[[1;*H
```

Another speciality about these codes is that they are not overwritten by another code. That is to avoid that the codes obtained from xterm directly `t_RV` overwrite them.

Another special value is a termcap entry ending in "@;*X". This is for cursor keys, which either use "CSI X" or "CSI 1 ; modifier X". Thus the "@" stands for either "1" if a modifier follows, or nothing.

arrow_modifiers

Several terminal emulators (alacritty, gnome, konsole, etc.) send special codes for keys with modifiers, but these do not have an entry in the termcap/terminfo database. You can make them work by adding a few lines in your vimrc. For example, to make the Control modifier work with arrow keys for the gnome terminal:

```
if &term =~ 'gnome'
    execute "set <xUp>=\<Esc>[@;*A"
    execute "set <xDown>=\<Esc>[@;*B"
    execute "set <xRight>=\<Esc>[@;*C"
    execute "set <xLeft>=\<Esc>[@;*D"
endif
```

xterm-scroll-region

The default termcap entry for xterm on Sun and other platforms does not contain the entry for scroll regions. Add ":cs=\E[%i%d;%dr:" to the xterm entry in /etc/termcap and everything should work.

xterm-end-home-keys

On some systems (at least on FreeBSD with XFree86 3.1.2) the codes that the <End> and <Home> keys send contain a <Null> character. To make these keys send the proper key code, add these lines to your ~/.Xdefaults file:

```
*VT100.Translations:          #override \n\
    <Key>Home: string("\0x1b") string("[7~") \n\
    <Key>End: string("\0x1b") string("[8~")
```

xterm-8bit xterm-8-bit

Xterm can be run in a mode where it uses 8-bit escape sequences. The CSI code is used instead of <Esc>[. The advantage is that an <Esc> can quickly be recognized in Insert mode, because it can't be confused with the start of a special key.

For the builtin termcap entries, Vim checks if the 'term' option contains "8bit" anywhere. It then uses 8-bit characters for the termcap entries, the mouse and a few other things. You would normally set \$TERM in your shell to "xterm-8bit" and Vim picks this up and adjusts to the 8-bit setting automatically.

When Vim receives a response to the t_RV (request version) sequence and it starts with CSI, it assumes that the terminal is in 8-bit mode and will convert all key sequences to their 8-bit variants.

xterm-terminfo-entries

For some time the terminfo entries were insufficient to describe all the features that Vim can use. The builtin xterm termcap entries did have these, with the result that several terminals that were similar enough to xterm took advantage of these by prefixing "xterm-" to the terminal name in \$TERM.

This leads to problems, because quite often these terminals are not 100% compatible with xterm. At the start of 2023 several entries have been added to the terminfo database to make it possible to use these features without using the "xterm" workaround. These are the relevant entries (so far):

| name | xterm value | description |
|------|---|--|
| RV | "\033[>c" | Request version <code>t_RV</code> |
| BE | "\033[?2004h" | enable bracketed paste mode <code>t_BE</code> |
| BD | "\033[?2004l" | disable bracketed paste mode <code>t_BD</code> |
| PS | "\033[200~" | pasted text start <code>t_PS</code> |
| PE | "\033[201~" | pasted text end <code>t_PE</code> |
| XM | "\033[?1006;1004;1000%?%p1%{1}%=%th%el%;" | mouse enable / disable <code>t_XM</code> |
| FE | "\033[?1004h" | enable focus event tracking <code>t_fe</code> |
| FD | "\033[?1004l" | disable focus event tracking <code>t_fd</code> |

The "XM" entry includes "1006" to enable SGR style mouse reporting. This supports columns above 223. It also includes "1004" which enables focus reporting.

Note: As of 2023, the "1004" is currently not used by Vim itself, instead it is recommended to set focus reporting independently of mouse tracking by the `t_fe` and `t_fd` entries, as ncurses also starts to use with the latest versions (and will then also end up in terminfo/termcap).

xterm-kitty kitty-terminal

The Kitty terminal is a special case. Mainly because it works differently from most other terminals, but also because, instead of trying to fit in and make it behave like other terminals by default, it dictates how applications need to work when using Kitty. This makes it very difficult for Vim to work in a Kitty terminal. Some exceptions have been hard coded, but it is not at all nice to have to make exceptions for one specific terminal.

One of the problems is that the value for \$TERM is set to "xterm-kitty". For Vim this is an indication that the terminal is xterm-compatible and the builtin xterm termcap entries should be used. Many other terminals depend on this. However, Kitty is not fully xterm compatible. The author suggested to ignore the "xterm-" prefix and use the terminfo entry anyway, so that is what happens now, the builtin xterm termcap entries are not used. However, the `t_RV` is set, otherwise other things would not work, such as automatically setting `'tymouse'` to "sgr" (at least until `t_XM` is being used for this).

It is not clear why kitty sets \$TERM to "xterm-kitty", the terminal isn't really xterm compatible. "kitty" would be more appropriate, but a terminfo entry with that name is not widespread.

Note that using the kitty keyboard protocol is a separate feature, see [kitty-keyboard-protocol](#) .

2. Terminal options terminal-options termcap-options E436

The terminal options can be set just like normal options. But they are not shown with the `":set all"` command. Instead use `":set termcap"`.

It is always possible to change individual strings by setting the appropriate option. For example:

```
:set t_ce=^V^[K          (CTRL-V, <Esc>, [, K)
```

The options are listed below. The associated termcap code is always equal to the last two characters of the option name. Only one termcap code is required: Cursor motion, 't_cm'.

The options 't_da', 't_db', 't_ms', 't_xs', 't_xn', 't_xo' represent flags in the termcap. When the termcap flag is present, the option will be set to "y". But any non-empty string means that the flag is set. An empty string means that the flag is not set. 't_CS' works like this too, but it isn't a termcap flag.

OUTPUT CODES

terminal-output-codes

option meaning

| | | | |
|------|--|-----------|--------|
| t_AB | set background color (ANSI) | t_AB | 't_AB' |
| t_AF | set foreground color (ANSI) | t_AF | 't_AF' |
| t_AL | add number of blank lines | t_AL | 't_AL' |
| t_al | add new blank line | t_al | 't_al' |
| t_bc | backspace character | t_bc | 't_bc' |
| t_cd | clear to end of screen | t_cd | 't_cd' |
| t_ce | clear to end of line | t_ce | 't_ce' |
| t_cl | clear screen | t_cl | 't_cl' |
| t_cm | cursor motion (required!) | E437 t_cm | 't_cm' |
| t_Co | number of colors | t_Co | 't_Co' |
| t_CS | if non-empty, cursor relative to scroll region | t_CS | 't_CS' |
| t_cs | define scrolling region | t_cs | 't_cs' |
| t_CV | define vertical scrolling region | t_CV | 't_CV' |
| t_da | if non-empty, lines from above scroll down | t_da | 't_da' |
| t_db | if non-empty, lines from below scroll up | t_db | 't_db' |
| t_DL | delete number of lines | t_DL | 't_DL' |
| t_dl | delete line | t_dl | 't_dl' |
| t_fs | set window title end (from status line) | t_fs | 't_fs' |
| t_ke | exit "keypad transmit" mode | t_ke | 't_ke' |
| t_ks | start "keypad transmit" mode | t_ks | 't_ks' |
| t_le | move cursor one char left | t_le | 't_le' |
| t_mb | blinking mode | t_mb | 't_mb' |
| t_md | bold mode | t_md | 't_md' |
| t_me | Normal mode (undoes t_mr, t_mb, t_md and color) | t_me | 't_me' |
| t_mr | reverse (invert) mode | t_mr | 't_mr' |
| t_ms | | t_ms | 't_ms' |
| t_ms | if non-empty, cursor can be moved in standout/inverse mode | | |
| t_nd | non destructive space character | t_nd | 't_nd' |
| t_op | reset to original color pair | t_op | 't_op' |
| t_RI | cursor number of chars right | t_RI | 't_RI' |
| t_Sb | set background color | t_Sb | 't_Sb' |
| t_Sf | set foreground color | t_Sf | 't_Sf' |
| t_se | standout end | t_se | 't_se' |
| t_so | standout mode | t_so | 't_so' |
| t_sr | scroll reverse (backward) | t_sr | 't_sr' |
| t_te | end of "termcap" mode | t_te | 't_te' |
| t_ti | put terminal into "termcap" mode | t_ti | 't_ti' |
| t_ts | set window title start (to status line) | t_ts | 't_ts' |
| t_ue | underline end | t_ue | 't_ue' |

| | | | |
|------|---|------|--------|
| t_us | underline mode | t_us | 't_us' |
| t_ut | clearing uses the current background color | t_ut | 't_ut' |
| t_vb | visual bell | t_vb | 't_vb' |
| t_ve | cursor visible | t_ve | 't_ve' |
| t_vi | cursor invisible | t_vi | 't_vi' |
| t_vs | cursor very visible (blink) | t_vs | 't_vs' |
| | | t_xs | 't_xs' |
| t_xs | if non-empty, standout not erased by overwriting (hpterm) | t_xn | 't_xn' |
| t_xn | if non-empty, writing a character at the last screen cell does not cause scrolling | | |
| | | t_xo | 't_xo' |
| t_xo | if non-empty, terminal uses xon/xoff handshaking, mapping CTRL-S will not be possible then, since it is used for flow control (used by vt420 terminal). Setting this flag has only an effect when starting Vim. | | |
| t_ZH | italics mode | t_ZH | 't_ZH' |
| t_ZR | italics end | t_ZR | 't_ZR' |

Added by Vim (there are no standard codes for these):

| | | | |
|------|---|------|--------|
| t_AU | set underline color (ANSI) | t_AU | 't_AU' |
| t_Ce | undercurl and underline end | t_Ce | 't_Ce' |
| t-Cs | undercurl (curly underline) mode | t-Cs | 't-Cs' |
| t_CF | set alternate font (using index 0 - 10) | t_CF | 't_CF' |
| t_Us | double underline mode | t_Us | 't_Us' |
| t_ds | dotted underline mode | t_ds | 't_ds' |
| t_Ds | dashed underline mode | t_Ds | 't_Ds' |
| t_Te | strikethrough end | t_Te | 't_Te' |
| t_Ts | strikethrough mode | t_Ts | 't_Ts' |
| t_IS | set icon text start | t_IS | 't_IS' |
| t_IE | set icon text end | t_IE | 't_IE' |
| t_WP | set window position (Y, X) in pixels | t_WP | 't_WP' |
| t_GP | get window position (Y, X) in pixels | t_GP | 't_GP' |
| t_WS | set window size (height, width in cells) | t_WS | 't_WS' |
| t_VS | cursor normally visible (no blink) | t_VS | 't_VS' |
| t_SI | start insert mode (bar cursor shape) | t_SI | 't_SI' |
| t_SR | start replace mode (underline cursor shape) | t_SR | 't_SR' |
| t_EI | end insert or replace mode (block cursor shape) | t_EI | 't_EI' |
| | termcap-cursor-shape | | |
| t_RV | request terminal version string (works for xterm and other terminal emulators) The response is stored in v:termresponse xterm-8bit 'ttymouse' xterm-codes | t_RV | 't_RV' |
| t_XM | enable/disable mouse reporting, see mouse-reporting below | t_XM | 't_XM' |
| t_RK | request terminal keyboard protocol state; sent after t_TI | t_RK | 't_RK' |
| t_u7 | request cursor position (for xterm) see 'ambiwidth' | t_u7 | 't_u7' |
| | The response is stored in v:termu7resp | | |
| t_RF | request terminal foreground color | t_RF | 't_RF' |
| | The response is stored in v:termrfgresp | | |
| t_RB | request terminal background color | t_RB | 't_RB' |
| | The response is stored in v:termrbgresp | | |

| | | | |
|------|---|------|--------|
| t_8f | set foreground color (R, G, B)
xterm-true-color | t_8f | 't_8f' |
| t_8b | set background color (R, G, B)
xterm-true-color | t_8b | 't_8b' |
| t_8u | set underline color (R, G, B) | t_8u | 't_8u' |
| t_BE | enable bracketed paste mode
xterm-bracketed-paste | t_BE | 't_BE' |
| t_BD | disable bracketed paste mode
xterm-bracketed-paste | t_BD | 't_BD' |
| t_SC | set cursor color start | t_SC | 't_SC' |
| t_EC | set cursor color end | t_EC | 't_EC' |
| t_SH | set cursor shape | t_SH | 't_SH' |
| t_RC | request terminal cursor blinking
The response is stored in v:termblinkresp | t_RC | 't_RC' |
| t_RS | request terminal cursor style
The response is stored in v:termstyleresp | t_RS | 't_RS' |
| t_ST | save window title to stack | t_ST | 't_ST' |
| t_RT | restore window title from stack | t_RT | 't_RT' |
| t_Si | save icon text to stack | t_Si | 't_Si' |
| t_Ri | restore icon text from stack | t_Ri | 't_Ri' |
| t_TE | end of "raw" mode | t_TE | 't_TE' |
| t_TI | put terminal into "raw" mode | t_TI | 't_TI' |
| t_fe | enable focus-event tracking
xterm-focus-event | t_fe | 't_fe' |
| t_fd | disable focus-event tracking
xterm-focus-event | t_fd | 't_fd' |

Some codes have a start, middle and end part. The start and end are defined by the termcap option, the middle part is text.

```
set title text:      t_ts {title text} t_fs
set icon text:      t_IS {icon text} t_IE
set cursor color:   t_SC {color name} t_EC
```

t_SH must take one argument:

```
0, 1 or none      blinking block cursor
2                  block cursor
3                  blinking underline cursor
4                  underline cursor
5                  blinking vertical bar cursor
6                  vertical bar cursor
```

t_RS is sent only if the response to t_RV has been received. It is not used on Mac OS when Terminal.app could be recognized from the termresponse.

mouse-reporting

Many terminals can report mouse clicks and some can report mouse movement and dragging. Vim needs to know what codes are being used for this.

The "XM" terminfo/termcap entry is used for this. Vim also has the **'ttymouse'** option to specify the mouse protocol being used. See the option for the possible values.

If Vim can read the "XM" terminfo/termcap entry then it will be used for enabling and disabling the mouse reporting. If it is missing, then the value

from `'ttymouse'` is used to decide how to do this.

If the "XM" entry exists and the first number is "1006" then `'ttymouse'` will be set to "sgr", unless it was already set earlier.

KEY CODES

terminal-key-codes

Note: Use the `<>` form if possible

| option | name | meaning | | |
|--------|-----------|------------------------|------------|--------|
| t_ku | <Up> | arrow up | t_ku | 't_ku' |
| t_kd | <Down> | arrow down | t_kd | 't_kd' |
| t_kr | <Right> | arrow right | t_kr | 't_kr' |
| t_kl | <Left> | arrow left | t_kl | 't_kl' |
| | <xUp> | alternate arrow up | <xUp> | |
| | <xDown> | alternate arrow down | <xDown> | |
| | <xRight> | alternate arrow right | <xRight> | |
| | <xLeft> | alternate arrow left | <xLeft> | |
| | <S-Up> | shift arrow up | | |

| t_KL | <k9> | keypad 9 | <k9> t_KL | 't_KL' |
| | <Mouse> | leader of mouse code | <Mouse> | |
| t_PS | <PasteStart> | start of bracketed paste | t_PS | 't_PS' |
| | | xterm-bracketed-paste | | |
| t_PE | <PasteEnd> | end of bracketed paste | t_PE | 't_PE' |
| | | xterm-bracketed-paste | | |
| | <FocusGained> | Vim window got focus (internal only) | | |
| | <FocusLost> | Vim window lost focus (internal only) | | |

Note about t_so and t_mr: When the termcap entry "so" is not present the entry for "mr" is used. And vice versa. The same is done for "se" and "me".

If your terminal supports both inversion and standout mode, you can see two different modes. If your terminal supports only one of the modes, both will look the same.

keypad-comma

The keypad keys, when they are not mapped, behave like the equivalent normal key. There is one exception: if you have a comma on the keypad instead of a decimal point, Vim will use a dot anyway. Use these mappings to fix that:

```
:noremap <kPoint> ,  
:noremap! <kPoint> ,
```

xterm-codes

There is a special trick to obtain the key codes which currently only works for xterm. When `t_RV` is defined and a response is received which indicates an xterm with patchlevel 141 or higher, Vim uses special escape sequences to request the key codes directly from the xterm. The responses are used to adjust the various `t_` codes. This avoids the problem that the xterm can produce different codes, depending on the mode it is in (8-bit, VT102, VT220, etc.). The result is that codes like `<xF1>` are no longer needed.

One of the codes that can change is `'t_Co'`, the number of colors. This will trigger a redraw. If this is a problem, reset the `'xtermcodes'` option as early as possible:

```
set noxtermcodes
```

Note: Requesting the key codes is only done on startup. If the xterm options are changed after Vim has started, the escape sequences may not be recognized anymore.

xterm-true-color

Vim supports using true colors in the terminal (taken from `highlight-guifg` and `highlight-guibg`), given that the terminal supports this. To make this work the `'termguicolors'` option needs to be set.

See <https://github.com/termstandard/colors> for a list of terminals that support true colors.

For telling the terminal what RGB color to use the `t_8f` and `t_8b` termcap entries are used. These are set by default to values that work for most terminals. If that does not work for your terminal you can set them manually. The default values are set like this:

```
let &t_8f = "\<Esc>[38;2;%lu;%lu;%lum"  
let &t_8b = "\<Esc>[48;2;%lu;%lu;%lum"
```

Some terminals accept similar sequences, with semicolons replaced by colons and an extra colon after the number 2 (this is conformant to the ISO 8613-6 standard, but less widely supported):

```
let &t_8f = "\<Esc>[38:2::%lu;%lu;%lum"  
let &t_8b = "\<Esc>[48:2::%lu;%lu;%lum"
```

These options contain printf strings, with `printf()` (actually, its C equivalent hence ``l`` modifier) invoked with the `t_` option value and three unsigned long integers that may have any value between 0 and 255 (inclusive) representing red, green and blue colors respectively.

xterm-resize

Window resizing with xterm only works if the allowWindowOps resource is enabled. On some systems and versions of xterm it's disabled by default because someone thought it would be a security issue. It's not clear if this is actually the case.

To overrule the default, put this line in your ~/.Xdefaults or ~/.Xresources:

```
XTerm*allowWindowOps:      true
```

And run "xrdb -merge .Xresources" to make it effective. You can check the value with the context menu (right mouse button while CTRL key is pressed), there should be a tick at allow-window-ops.

xterm-focus-event

Some terminals including xterm support the focus event tracking feature. If this feature is enabled by the 't_fe' sequence, special key sequences are sent from the terminal to Vim every time the terminal gains or loses focus. Vim fires focus events (FocusGained||FocusLost) by handling them accordingly. Focus event tracking is disabled by a 't_fd' sequence when exiting "raw" mode. If you would like to disable this feature, add the following to your .vimrc:

```
set t_fd=  
set t_fe=
```

If your terminal does support this but Vim does not recognize the terminal, you may have to set the options yourself:

```
let &t_fe = "\<Esc>[?1004h"  
let &t_fd = "\<Esc>[?1004l"  
execute "set <FocusGained>=\<Esc>[I"  
execute "set <FocusLost>=\<Esc>[O"
```

If this causes garbage to show when Vim starts up then it doesn't work.

termcap-colors

Note about colors: The 't_Co' option tells Vim the number of colors available. When it is non-zero, the 't_AB' and 't_AF' options are used to set the color. If one of these is not available, 't_Sb' and 't_Sf' are used. 't_me' is used to reset to the default colors. Also see 'termguicolors'. When the GUI is running 't_Co' is set to 16777216.

termcap-cursor-shape termcap-cursor-color

When Vim enters Insert mode the 't_SI' escape sequence is sent. When Vim enters Replace mode the 't_SR' escape sequence is sent if it is set, otherwise 't_SI' is sent. When leaving Insert mode or Replace mode 't_EI' is used.

Note: When 't_EI' is not set then 't_SI' and 't_SR' will not be sent. And when 't_SI' or 't_SR' is not set then 't_EI' is sent only once.

This can be used to change the shape or color of the cursor in Insert or Replace mode. These are not standard termcap/terminfo entries, you need to set them yourself.

Example for an xterm, this changes the color of the cursor:

```
if &term =~ "xterm"  
  let &t_SI = "\<Esc>]12;purple\x7"  
  let &t_SR = "\<Esc>]12;red\x7"  
  let &t_EI = "\<Esc>]12;blue\x7"  
endif
```

NOTE: When Vim exits the shape for Normal mode will remain. The shape from before Vim started will not be restored.

For Windows Terminal you can use something like this:

```
" Note: This should be set after `set termguicolors` or `set t_Co=256`.
if &term =~ 'xterm' || &term == 'win32'
  " Use DECSCUSR escape sequences
  let &t_SI = "\e[5 q"    " blink bar
  let &t_SR = "\e[3 q"    " blink underline
  let &t_EI = "\e[1 q"    " blink block
  let &t_ti .= "\e[1 q"   " blink block
  let &t_te .= "\e[0 q"   " default (depends on terminal, normally blink
                          " block)
endif
```

{not available when compiled without the |+cursorshape| feature}

termcap-title

The **'t_ts'** and **'t_fs'** options are used to set the window title if the terminal allows title setting via sending strings. They are sent before and after the title string, respectively. Similar **'t_IS'** and **'t_IE'** are used to set the icon text. These are Vim-internal extensions of the Unix termcap, so they cannot be obtained from an external termcap. However, the builtin termcap contains suitable entries for xterm and iris-ansi, so you don't need to set them here.

hpterm

If inversion or other highlighting does not work correctly, try setting the **'t_xs'** option to a non-empty string. This makes the **'t_ce'** code be used to remove highlighting from a line. This is required for "hpterm". Setting the **'weirdinvert'** option has the same effect as making **'t_xs'** non-empty, and vice versa.

scroll-region

Some termcaps do not include an entry for "cs" (scroll region), although the terminal does support it. For example: xterm on a Sun. You can use the builtin_xterm or define t_cs yourself. For example:

```
:set t_cs=^V^[[%i%d;%dr
```

Where ^V is **CTRL-V** and ^[is **<Esc>**.

The vertical scroll region t_CV is not a standard termcap code. Vim uses it internally in the GUI. But it can also be defined for a terminal, if you can find one that supports it. The two arguments are the left and right column of the region which to restrict the scrolling to. Just like t_cs defines the top and bottom lines. Defining t_CV will make scrolling in vertically split windows a lot faster. Don't set t_CV when t_da or t_db is set (text isn't cleared when scrolling).

Unfortunately it is not possible to deduce from the termcap how cursor positioning should be done when using a scrolling region: Relative to the beginning of the screen or relative to the beginning of the scrolling region. Most terminals use the first method. The **'t_CS'** option should be set to any string when cursor positioning is relative to the start of the scrolling region. It should be set to an empty string otherwise.

Note for xterm users: The shifted cursor keys normally don't work. You can make them work with the xmodmap command and some mappings in Vim.

Give these commands in the xterm:

```
xmodmap -e "keysym Up = Up F13"  
xmodmap -e "keysym Down = Down F16"  
xmodmap -e "keysym Left = Left F18"  
xmodmap -e "keysym Right = Right F19"
```

And use these mappings in Vim:

```
:map <t_F3> <S-Up>  
:map! <t_F3> <S-Up>  
:map <t_F6> <S-Down>  
:map! <t_F6> <S-Down>  
:map <t_F8> <S-Left>  
:map! <t_F8> <S-Left>  
:map <t_F9> <S-Right>  
:map! <t_F9> <S-Right>
```

Instead of, say, <S-Up> you can use any other command that you want to use the shift-cursor-up key for. (Note: To help people that have a Sun keyboard with left side keys F14 is not used because it is confused with the undo key; F15 is not used, because it does a window-to-front; F17 is not used, because it closes the window. On other systems you can probably use them.)

3. Window size

window-size

[This is about the size of the whole window Vim is using, not a window that is created with the ":split" command.]

If you are running Vim on an Amiga and the terminal name is "amiga" or "builtin_amiga", the amiga-specific window resizing will be enabled. On Unix systems three methods are tried to get the window size:

- an ioctl call (TIOCGSIZE or TIOCGWINSZ, depends on your system)
- the environment variables "LINES" and "COLUMNS"
- from the termcap entries "li" and "co"

If everything fails a default size of 24 lines and 80 columns is assumed. If a window-resize signal is received the size will be set again. If the window size is wrong you can use the 'lines' and 'columns' options to set the correct values.

One command can be used to set the screen size:

```
:mod[e] [mode] :mod :mode E359
```

Without argument this only detects the screen size and redraws the screen. [mode] was used on MS-DOS, but it doesn't work anymore. In Vim9 this command is not supported.

4. Slow and fast terminals

slow-fast-terminal

slow-terminal

If you have a fast terminal you may like to set the **'ruler'** option. The cursor position is shown in the status line. If you are using horizontal scrolling ('wrap' option off) consider setting **'sidescroll'** to a small number.

If you have a slow terminal you may want to reset the **'showcmd'** option. The command characters will not be shown in the status line. If the terminal scrolls very slowly, set the **'scrolljump'** to 5 or so. If the cursor is moved off the screen (e.g., with "j") Vim will scroll 5 lines at a time. Another possibility is to reduce the number of lines that Vim uses with the command "z{height}<CR>".

If the characters from the terminal are arriving with more than 1 second between them you might want to set the **'timeout'** and/or **'ttimeout'** option. See the "Options" chapter [options](#) .

If your terminal does not support a scrolling region, but it does support insert/delete line commands, scrolling with multiple windows may make the lines jump up and down. This would happen if the **'ttyfast'** option has been reset. Check that with:

```
verbose set ttyfast?
```

If your terminal scrolls very slowly, but redrawing is not slow, set the **'ttyscroll'** option to a small number, e.g., 3. This will make Vim redraw the screen instead of scrolling, when there are more than 3 lines to be scrolled.

If you are using a color terminal that is slow, use this command:

```
hi NonText cterm=NONE ctermfg=NONE
```

This avoids that spaces are sent when they have different attributes. On most terminals you can't see this anyway.

If you are using Vim over a slow serial line, you might want to try running Vim inside the "screen" program. Screen will optimize the terminal I/O quite a bit.

If you are testing termcap options, but you cannot see what is happening, you might want to set the **'writedelay'** option. When non-zero, one character is sent to the terminal at a time. This makes the screen updating a lot slower, making it possible to see what is happening.

5. Using the mouse

mouse-using

This section is about using the mouse on a terminal or a terminal window. How to use the mouse in a GUI window is explained in [gui-mouse](#) . For scrolling with a mouse wheel see [scroll-mouse-wheel](#) .

Don't forget to enable the mouse with this command:

```
:set mouse=a
```

Otherwise Vim won't recognize the mouse in all modes (See **'mouse'**).

Currently the mouse is supported for Unix in an xterm window, in a *BSD

console with `sysmouse` , in a Linux console (with GPM `gpm-mouse`), and in a Windows console.
Mouse clicks can be used to position the cursor, select an area and paste.

These characters in the `'mouse'` option tell in which situations the mouse will be used by Vim:

| | |
|---|--|
| n | Normal mode |
| v | Visual mode |
| i | Insert mode |
| c | Command-line mode |
| h | all previous modes when in a help file |
| a | all previous modes |
| r | for <code>hit-enter</code> prompt |

The default for `'mouse'` is empty, the mouse is not used. Normally you would do:

```
:set mouse=a
```

to start using the mouse (this is equivalent to setting `'mouse'` to "nvich"). If you only want to use the mouse in a few modes or also want to use it for the two questions you will have to concatenate the letters for those modes. For example:

```
:set mouse=nv
```

Will make the mouse work in Normal mode and Visual mode.

```
:set mouse=h
```

Will make the mouse work in help files only (so you can use "g<LeftMouse>" to jump to tags).

Whether the selection that is started with the mouse is in Visual mode or Select mode depends on whether "mouse" is included in the `'selectmode'` option.

terminal-mouse

In an xterm, with the currently active mode included in the `'mouse'` option, normal mouse clicks are used by Vim, mouse clicks with the shift or ctrl key pressed go to the xterm. With the currently active mode not included in `'mouse'` all mouse clicks go to the xterm.

For terminals where it is not possible to have the mouse events be used by the terminal itself by using a modifier, a workaround is to not use mouse events for Vim in command-line mode:

```
:set mouse=nvi
```

Then to select text with the terminal, use ":" to go to command-line mode, select and copy the text to the system, then press Esc.

Another way is to temporarily use ":sh" to run a shell, copy the text, then exit the shell. `'mouse'` can remain set to "a" then.

xterm-clipboard

In the Motif GUI version, when running in a terminal and there is access to the X-server (DISPLAY is set), the copy and paste will behave like in the GUI. If not, the middle mouse button will insert the unnamed register. In that case, here is how you copy and paste a piece of text:

Copy/paste with the mouse and Visual mode (`'mouse'` option must be set, see above):

1. Press left mouse button on first letter of text, move mouse pointer to last

letter of the text and release the button. This will start Visual mode and highlight the selected area.

2. Press "y" to yank the Visual text in the unnamed register.
3. Click the left mouse button at the insert position.
4. Click the middle mouse button.

Shortcut: If the insert position is on the screen at the same time as the Visual text, you can do 2, 3 and 4 all in one: Click the middle mouse button at the insert position.

Note: When the `-X` command line argument is used, Vim will not connect to the X server and copy/paste to the X clipboard (selection) will not work. Use the shift key with the mouse buttons to let the xterm do the selection.

xterm-command-server

When the X-server clipboard is available, the command server described in `x11-clientserver` can be enabled with the `--servername` command line argument.

xterm-copy-paste

NOTE: In some (older) xterms, it's not possible to move the cursor past column 95 or 223. This is an xterm problem, not Vim's. Get a newer xterm `color-xterm`. Also see `'ttymouse'`.

Copy/paste in xterm with (current mode NOT included in `'mouse'`):

1. Press left mouse button on first letter of text, move mouse pointer to last letter of the text and release the button.
2. Use normal Vim commands to put the cursor at the insert position.
3. Press "a" to start Insert mode.
4. Click the middle mouse button.
5. Press ESC to end Insert mode.

(The same can be done with anything in `'mouse'` if you keep the shift key pressed while using the mouse.)

Note: if you lose the 8th bit when pasting (special characters are translated into other characters), you may have to do `"stty cs8 -istrip -parenb"` in your shell before starting Vim.

Thus in an xterm the shift and ctrl keys cannot be used with the mouse. Mouse commands requiring the CTRL modifier can be simulated by typing the "g" key before using the mouse:

```
"g<LeftMouse>" is "<C-LeftMouse>"      (jump to tag under mouse click)
"g<RightMouse>" is "<C-RightMouse>"     ("CTRL-T")
```

mouse-mode-table mouse-overview

A short overview of what the mouse buttons do, when `'mousemodel'` is "extend":

Normal Mode:

| event | position
cursor | selection | change
window | action |
|---------------|--------------------|---------------------|------------------|-----------------------|
| <LeftMouse> | yes | end | yes | |
| <C-LeftMouse> | yes | end | yes | "CTRL-]" (2) |
| <S-LeftMouse> | yes | no change | yes | "*" (2) <S-LeftMouse> |
| <LeftDrag> | yes | start or extend (1) | no | <LeftDrag> |
| <LeftRelease> | yes | start or extend (1) | no | |

| | | | | | |
|----------------|-----|-------------------------|-----|--------------|----------------|
| <MiddleMouse> | yes | if not active | no | put | |
| <MiddleMouse> | yes | if active | no | yank and put | |
| <RightMouse> | yes | start or extend | yes | | |
| <A-RightMouse> | yes | start or extend blockw. | yes | | <A-RightMouse> |
| <S-RightMouse> | yes | no change | yes | "#" (2) | <S-RightMouse> |
| <C-RightMouse> | no | no change | no | "CTRL-T" | |
| <RightDrag> | yes | extend | no | | <RightDrag> |
| <RightRelease> | yes | extend | no | | <RightRelease> |

Insert or Replace Mode:

| event | position
cursor | selection | change
window | action | |
|----------------|--------------------|-------------------------|------------------|-----------------|--|
| <LeftMouse> | yes | (cannot be active) | yes | | |
| <C-LeftMouse> | yes | (cannot be active) | yes | "CTRL-O^]" (2) | |
| <S-LeftMouse> | yes | (cannot be active) | yes | "CTRL-O*" (2) | |
| <LeftDrag> | yes | start or extend (1) | no | like CTRL-O (1) | |
| <LeftRelease> | yes | start or extend (1) | no | like CTRL-O (1) | |
| <MiddleMouse> | no | (cannot be active) | no | put register | |
| <RightMouse> | yes | start or extend | yes | like CTRL-O | |
| <A-RightMouse> | yes | start or extend blockw. | yes | | |
| <S-RightMouse> | yes | (cannot be active) | yes | "CTRL-O#" (2) | |
| <C-RightMouse> | no | (cannot be active) | no | "CTRL-O CTRL-T" | |

In a help window:

| event | position
cursor | selection | change
window | action | |
|---------------|--------------------|--------------------|------------------|-------------------------|--|
| <2-LeftMouse> | yes | (cannot be active) | no | "^]" (jump to help tag) | |

When **'mousemodel'** is "popup", these are different:

Normal Mode:

| event | position
cursor | selection | change
window | action | |
|---------------|--------------------|-------------------------|------------------|--------|---------------|
| <S-LeftMouse> | yes | start or extend (1) | no | | |
| <A-LeftMouse> | yes | start or extend blockw. | no | | <A-LeftMouse> |
| <RightMouse> | no | popup menu | no | | |

Insert or Replace Mode:

| event | position
cursor | selection | change
window | action | |
|---------------|--------------------|-------------------------|------------------|-----------------|--|
| <S-LeftMouse> | yes | start or extend (1) | no | like CTRL-O (1) | |
| <A-LeftMouse> | yes | start or extend blockw. | no | | |
| <RightMouse> | no | popup menu | no | | |

- (1) only if mouse pointer moved since press
- (2) only if click is in same buffer

Clicking the left mouse button causes the cursor to be positioned. If the click is in another window that window is made the active window. When editing the command-line the cursor can only be positioned on the command-line. When in Insert mode Vim remains in Insert mode. If **'scrolloff'** is set, and the cursor is positioned within **'scrolloff'** lines from the window border, the text is scrolled.

A selection can be started by pressing the left mouse button on the first character, moving the mouse to the last character, then releasing the mouse button. You will not always see the selection until you release the button, only in some versions (GUI, Win32) will the dragging be shown immediately. **Note** that you can make the text scroll by moving the mouse at least one character in the first/last line in the window when **'scrolloff'** is non-zero.

In Normal, Visual and Select mode clicking the right mouse button causes the Visual area to be extended. When **'mousemodel'** is "popup", the left button has to be used while keeping the shift key pressed. When clicking in a window which is editing another buffer, the Visual or Select mode is stopped.

In Normal, Visual and Select mode clicking the right mouse button with the alt key pressed causes the Visual area to become blockwise. When **'mousemodel'** is "popup" the left button has to be used with the alt key. **Note** that this won't work on systems where the window manager consumes the mouse events when the alt key is pressed (it may move the window).

double-click

Double, triple and quadruple clicks are supported when the GUI is active, for Win32, and for an xterm (if the gettimeofday() function is available). For selecting text, extra clicks extend the selection:

| click | select | |
|-----------|-------------------|---------------|
| double | word or % match | <2-LeftMouse> |
| triple | line | <3-LeftMouse> |
| quadruple | rectangular block | <4-LeftMouse> |

Exception: In a Help window a double click jumps to help for the word that is clicked on.

A double click on a word selects that word. **'iskeyword'** is used to specify which characters are included in a word. A double click on a character that has a match selects until that match (like using "v%"). If the match is an #if/#else/#endif block, the selection becomes linewise.

For MS-Windows and xterm the time for double clicking can be set with the **'mousetime'** option. For the other systems this time is defined outside of Vim. An example, for using a double click to jump to the tag under the cursor:

```
:map <2-LeftMouse> :exe "tag " .. expand("<cword>")<CR>
```

Dragging the mouse with a double click (button-down, button-up, button-down and then drag) will result in whole words to be selected. This continues until the button is released, at which point the selection is per character again.

For scrolling with the mouse see [scroll-mouse-wheel](#) .

gpm-mouse

The GPM mouse is only supported when the **+mouse_gpm** feature was enabled at compile time. The GPM mouse driver (Linux console) does not support quadruple clicks.

In Insert mode, when a selection is started, Vim goes into Normal mode temporarily. When Visual or Select mode ends, it returns to Insert mode. This is like using **CTRL-O** in Insert mode. Select mode is used when the **'selectmode'** option contains "mouse".

sysmouse

The `sysmouse` is only supported when the `+mouse_sysmouse` feature was enabled at compile time. The `sysmouse` driver (*BSD console) does not support keyboard modifiers.

drag-status-line

When working with several windows, the size of the windows can be changed by dragging the status line with the mouse. Point the mouse at a status line, press the left button, move the mouse to the new position of the status line, release the button. Just clicking the mouse in a status line makes that window the current window, without moving the cursor. If by selecting a window it will change position or size, the dragging of the status line will look confusing, but it will work (just try it).

<MiddleRelease> <MiddleDrag>

Mouse clicks can be mapped. The codes for mouse clicks are:

| code | mouse button | normal action | |
|-----------------|----------------------------|-------------------------------|-----------|
| <LeftMouse> | left pressed | set cursor position | |
| <LeftDrag> | left moved while pressed | extend selection | |
| <LeftRelease> | left released | set selection end | |
| <MiddleMouse> | middle pressed | paste text at cursor position | |
| <MiddleDrag> | middle moved while pressed | - | |
| <MiddleRelease> | middle released | - | |
| <RightMouse> | right pressed | extend selection | |
| <RightDrag> | right moved while pressed | extend selection | |
| <RightRelease> | right released | set selection end | |
| <X1Mouse> | X1 button pressed | - | X1Mouse |
| <X1Drag> | X1 moved while pressed | - | X1Drag |
| <X1Release> | X1 button release | - | X1Release |
| <X2Mouse> | X2 button pressed | - | X2Mouse |
| <X2Drag> | X2 moved while pressed | - | X2Drag |
| <X2Release> | X2 button release | - | X2Release |

The X1 and X2 buttons refer to the extra buttons found on some mice. The 'Microsoft Explorer' mouse has these buttons available to the right thumb. Currently X1 and X2 only work on Win32 and X11 environments.

Examples:

```
:noremap <MiddleMouse> <LeftMouse><MiddleMouse>
```

Paste at the position of the middle mouse button click (otherwise the paste would be done at the cursor position).

```
:noremap <LeftRelease> <LeftRelease>y
```

Immediately yank the selection, when using Visual mode.

Note the use of ":noremap" instead of "map" to avoid a recursive mapping.

```
:map <X1Mouse> <C-O>
:map <X2Mouse> <C-I>
```

Map the X1 and X2 buttons to go forwards and backwards in the jump list, see `CTRL-O` and `CTRL-I`.

mouse-swap-buttons

To swap the meaning of the left and right mouse buttons:

```
:noremap <LeftMouse> <RightMouse>
```

```
:noremap      <LeftDrag>      <RightDrag>
:noremap      <LeftRelease>  <RightRelease>
:noremap      <RightMouse>   <LeftMouse>
:noremap      <RightDrag>    <LeftDrag>
:noremap      <RightRelease>  <LeftRelease>
:noremap      g<LeftMouse>    <C-RightMouse>
:noremap      g<RightMouse>   <C-LeftMouse>
:noremap!     <LeftMouse>    <RightMouse>
:noremap!     <LeftDrag>     <RightDrag>
:noremap!     <LeftRelease>   <RightRelease>
:noremap!     <RightMouse>   <LeftMouse>
:noremap!     <RightDrag>    <LeftDrag>
:noremap!     <RightRelease>  <LeftRelease>
```

Terminal window support [terminal](#) [terminal-window](#)

The terminal feature is optional, use this to check if your Vim has it:

```
echo has('terminal')
```

If the result is "1" you have it.

{only available when compiled with the |+terminal| feature}

The terminal feature requires the +job and +channel features.

=====

| | |
|--------------|------------------------------|
| 1. Basic use | terminal-use |
|--------------|------------------------------|

This feature is for running a terminal emulator in a Vim window. A job can be started connected to the terminal emulator. For example, to run a shell:

```
:term bash
```

Or to run build command:

```
:term make myprogram
```

The job runs asynchronously from Vim, the window will be updated to show output from the job, also while editing in another window.

Typing

[terminal-typing](#)

When the keyboard focus is in the terminal window, typed keys will be sent to the job. This uses a pty when possible. You can click outside of the terminal window to move keyboard focus elsewhere.

CTRL-W can be used to navigate between windows and other **CTRL-W** commands, e.g.:

```
CTRL-W CTRL-W move focus to the next window
```

```
CTRL-W : enter an Ex command
```

See [CTRL-W](#) for more commands.

Special in the terminal window:

```
CTRL-W . send a CTRL-W to the job in the terminal
```

```
CTRL-W CTRL-\ send a CTRL-\ to the job in the terminal
```

```
CTRL-W N go to Terminal-Normal mode, see Terminal-mode
```

```
CTRL-\ CTRL-N go to Terminal-Normal mode, see Terminal-mode
```

```
CTRL-W " {reg} paste register {reg} t\_CTRL-W\_quote
```

Also works with the = register to insert the result of evaluating an expression.

```
CTRL-W CTRL-C ends the job, see below t\_CTRL-W\_CTRL-C
```

```
CTRL-W gt go to next tabpage, same as `gt` t\_CTRL-W\_gt
```

```
CTRL-W gT go to previous tabpage, same as `gT` t\_CTRL-W\_gT
```

See option '[termwinkey](#)' for specifying another key instead of **CTRL-W** that will work like **CTRL-W**. However, typing '[termwinkey](#)' twice sends '[termwinkey](#)' to the job. For example:

```
'termwinkey' CTRL-W move focus to the next window
```

```
'termwinkey' : enter an Ex command
```

```
'termwinkey' 'termwinkey' send 'termwinkey' to the job in the terminal
```

```
'termwinkey' . send 'termwinkey' to the job in the terminal
```

```
'termwinkey' CTRL-\ send a CTRL-\ to the job in the terminal
```

```
'termwinkey' N go to terminal Normal mode, see below
```

```
'termwinkey' CTRL-N same as CTRL-W N t\_CTRL-W\_N
```

```
'termwinkey' CTRL-C same as CTRL-W CTRL-C t\_CTRL-W\_CTRL-C
```

[t_CTRL-_CTRL-N](#)

The special key combination **CTRL-\ CTRL-N** can be used to switch to Normal mode, just like this works in any other mode.

[t_CTRL-W_CTRL-C](#)

CTRL-W CTRL-C can be typed to forcefully end the job. On MS-Windows a **CTRL-Break** will also kill the job.

If you type **CTRL-C** the effect depends on what the pty has been configured to

do. For simple commands this causes a SIGINT to be sent to the job, which would end it. Other commands may ignore the SIGINT or handle the **CTRL-C** themselves (like Vim does).

To change the keys you type use terminal mode mappings, see `:tmap`. These are defined like any mapping, but apply only when typing keys that are sent to the job running in the terminal. For example, to make F1 switch to Terminal-Normal mode:

```
tnoremap <F1> <C-W>N
```

You can use Esc, but you need to make sure it won't cause other keys to break (cursor keys start with an Esc, so they may break), this probably only works in the GUI:

```
tnoremap <Esc> <C-W>N
set notimeout ttimeout timeoutlen=100
```

You can also create menus similar to terminal mode mappings, but you have to use `:tmenu` instead of `:tmenu`.

options-in-terminal

After opening the terminal window and setting `'buftype'` to "terminal" the `TerminalWinOpen` autocommand event is triggered. This makes it possible to set options specifically for the terminal window and buffer. Example:

```
au TerminalWinOpen * setlocal bufhidden=hide
```

This only works properly if the terminal is not hidden.

For both hidden and non-hidden terminals this works, both for buffer-local and window-local options:

```
au TerminalWinOpen,BufWinEnter * if &buftype == 'terminal'
  \ | setlocal bufhidden=hide colorcolumn=123
  \ | endif
```

Note that for a hidden terminal the options are not set until the terminal is no longer hidden.

There is also the `TerminalOpen` event. Keep in mind this may be triggered for a hidden terminal, then the current window and buffer are not that of the new terminal.

You need to use `<abuf>`, which is set to the terminal buffer. Example:

```
au TerminalOpen * call setbufvar(expand('<abuf>')->str2nr(),
  \ '&termwscroll', 1000)
```

For a window-local option, you need to delay setting the option until the terminal window has been created (this only works for a hidden terminal):

```
au TerminalOpen * exe printf(
  \ 'au BufWinEnter <buffer=%d> ++once setlocal colorcolumn=%d',
  \ expand('<abuf>')->str2nr(), 123)
```

For a non-hidden terminal use `TerminalWinOpen`.

Mouse events (click and drag) are passed to the terminal. Mouse move events are only passed when Vim itself is receiving them. For a terminal that is when `'balloonevalterm'` is enabled.

Size and color

terminal-size-color

See option `'termwsize'` for controlling the size of the terminal window.

(TODO: scrolling when the terminal is larger than the window)

The job running in the terminal can change the colors. The default foreground and background colors are taken from Vim, the Normal highlight group.

For a color terminal the **'background'** option is used to decide whether the terminal window will start with a white or black background.

To use a different color the Terminal highlight group can be used, for example:

```
hi Terminal ctermbg=lightgrey ctermfg=blue guibg=lightgrey guifg=blue
```

Instead of Terminal another group can be specified with the "term_highlight" option for ``term_start()``.

In GUI mode or with **'termguicolors'**, the 16 ANSI colors used by default in new terminal windows may be configured using the variable ``g:terminal_ansi_colors``, which should be a list of 16 color names or hexadecimal color codes, similar to those accepted by `highlight-guifg`. When not using GUI colors, the terminal window always uses the 16 ANSI colors of the underlying terminal. When using ``term_start()`` the colors can be set with the "ansi_colors" option. The `term_setansicolors()` function can be used to change the colors, and `term_getansicolors()` to get the currently used colors.

Command syntax

```
:[range]ter[minal] [options] [command] :ter :terminal  
Open a new terminal window.
```

If `[command]` is provided run it as a job and connect the input and output to the terminal. If `[command]` is not given the **'shell'** option is used. if `[command]` is NONE no job is started, the pty of the terminal can be used by a command like gdb.

If `[command]` outputs NUL bytes, those will be converted to new lines `NL-used-for-Nul`.

Vim itself only recognizes `terminal-nospecial` characters inside `[command]`. Everything else will be passed untouched. When needed to expand wildcards, environment variables or other shell specials consider `term++shell` option.

If `[command]` is missing the default behavior is to close the terminal when the shell exits. This can be changed with the `++noclose` argument.

If `[command]` is present the default behavior is to keep the terminal open in Terminal-Normal mode. This can be changed with the `++close` argument.

No Vim command can follow, any | is included in [command]. Use `:execute` if you must have a Vim command following in the same line.

terminal-bufname

A new buffer will be created, using [command] or 'shell' as the name, prefixed with a "!". If a buffer by this name already exists a number is added in parentheses. E.g. if "gdb" exists the second terminal buffer will use "!gdb (1)".

If [range] is given the specified lines are used as input for the job. It will not be possible to type keys in the terminal window. For MS-Windows see the ++eof argument below.

term++close term++open

Supported [options] are:

++close The terminal window will close automatically when the job terminates.
terminal-close

++noclose The terminal window will NOT close automatically when the job terminates.

++open When the job terminates and no window shows it, a window will be opened.
Note that this can be interruptive.

The last of ++close, ++noclose and ++open matters and rules out earlier arguments.

++curwin Open the terminal in the current window, do not split the current window. Fails if the current buffer cannot be abandon ed.

++hidden Open the terminal in a hidden buffer, no window will be used.

++norestore Do not include this terminal window in a session file.

term++shell

++shell Instead of executing {command} directly, use a shell, like with `:!command` E279 {only works on Unix and MS-Windows} The resulting command will look like 'shell' 'shellcmdflag' [command] Other options related to `:!command` have no effect.

++kill={how} When trying to close the terminal window kill the job with {how}. See term_setkill() for the values.

++rows={height} Use {height} for the terminal window height. If the terminal uses the full Vim height (no window above or below the terminal window) the command line

height will be reduced as needed.

`++cols={width}` Use `{width}` for the terminal window width. If the terminal uses the full Vim width (no window left or right of the terminal window) this value is ignored.

`++eof={text}` When using `[range]: text` to send after the last line was written. Cannot contain white space. A CR is appended. For MS-Windows the default is to send **CTRL-D**.
E.g. for a shell use `"++eof=exit"` and for Python `"++eof=exit()"`. Special codes can be used like with `:map`, e.g. `"<C-Z"` for **CTRL-Z**.

`++type={pty}` (MS-Windows only): Use `{pty}` as the virtual console. See `'termwintype'` for the values.

`++api={expr}` Permit the function name starting with `{expr}` to be called as `terminal-api` function. If `{expr}` is empty then no function can be called.

If you want to use more options use the `term_start()` function.

If you want to split the window vertically, use:

`:vertical terminal`

Or short:

`:vert ter`

When the buffer associated with the terminal is forcibly unloaded or wiped out the job is killed, similar to calling ``job_stop(job, "kill")``.

Closing the window normally results in `E947`. When a kill method was set with `"++kill={how}"` or `term_setkill()` then closing the window will use that way to kill or interrupt the job. For example:

`:term ++kill=term tail -f /tmp/log`

So long as the job is running the window behaves like it contains a modified buffer. Trying to close the window with ``CTRL-W :quit`` fails. When using ``CTRL-W :quit!`` the job is ended. The text in the window is lost, the buffer is deleted. With ``CTRL-W :bunload!`` the buffer remains but will be empty.

Trying to close the window with ``CTRL-W :close`` also fails. Using ``CTRL-W :close!`` will close the window and make the buffer hidden.

You can use ``CTRL-W :hide`` to close the terminal window and make the buffer hidden, the job keeps running. The `:buffer` command can be used to turn the current window into a terminal window. If there are unsaved changes this fails, use `!` to force, as usual.

terminal-close

When the terminal job finishes and no `[command]` was given (e.g. the `'shell'` command was executed), the terminal window will be closed by default (unless the buffer in next window receiving the space has the `'nobuflisted'` option set,

in which case the terminal window would not be closed automatically, but a new empty buffer would be opened in that window).

When the terminal window is closed, e.g. when the shell exits and `++close` argument was used, and this is the last normal Vim window, then Vim will exit. This is like using `:quit` in a normal window. Help and preview windows are not counted.

To have a background job run without a window, and open the window when it's done, use options like this:

```
:term ++hidden ++open make
```

Note that the window will open at an unexpected moment, this will interrupt what you are doing.

[E947](#) [E948](#)

So long as the job is running, the buffer is considered modified and Vim cannot be quit easily, see [abandon](#) .

When the job has finished and no changes were made to the buffer: closing the window will wipe out the buffer.

Before changes can be made to a terminal buffer, the `'modifiable'` option must be set. This is only possible when the job has finished. At the first change the buffer will become a normal buffer and the highlighting is removed. You may want to change the buffer name with `:file` to be able to write, since the buffer name will still be set to the command.

Resizing

[terminal-resizing](#)

The size of the terminal can be in one of three modes:

1. The `'termwinsize'` option is empty: The terminal size follows the window size. The minimal size is 2 screen lines with 10 cells.
2. The `'termwinsize'` option is `"rows*cols"`, where `"rows"` is the minimal number of screen rows and `"cols"` is the minimal number of cells.
3. The `'termwinsize'` option is `"rowsXcols"` (where the `x` is upper or lower case). The terminal size is fixed to the specified number of screen lines and cells. If the window is bigger there will be unused empty space.

If the window is smaller than the terminal size, only part of the terminal can be seen (the lower-left part).

The `term_getsize()` function can be used to get the current size of the terminal. `term_setsize()` can be used only when in the first or second mode, not when `'termwinsize'` is `"rowsXcols"`.

Terminal-Job and Terminal-Normal mode

[Terminal-mode](#) [Terminal-Job](#)

When the job is running the contents of the terminal is under control of the job. That includes the cursor position. Typed keys are sent to the job.

The terminal contents can change at any time. This is called Terminal-Job mode.

Use **CTRL-W** N (or '**termwinkey**' N) to switch to Terminal-Normal mode. Now the contents of the terminal window is under control of Vim, the job output is suspended. **CTRL-** **CTRL-N** does the same.

Terminal-Job mode is where `:tmap` mappings are applied. Keys sent by `term_sendkeys()` are not subject to tmap, but keys from `feedkeys()` are.

It is not possible to enter Insert mode from Terminal-Job mode.

Terminal-Normal E946

In Terminal-Normal mode you can move the cursor around with the usual Vim commands, Visually mark text, yank text, etc. But you cannot change the contents of the buffer. The commands that would start insert mode, such as 'i' and 'a', return to Terminal-Job mode. The window will be updated to show the contents of the terminal. `:startinsert` is ineffective.

In Terminal-Normal mode the statusline and window title show "(Terminal)". If the job ends while in Terminal-Normal mode this changes to "(Terminal-finished)".

When the job outputs lines in the terminal, such that the contents scrolls off the top, those lines are remembered and can be seen in Terminal-Normal mode. The number of lines is limited by the '**termwinscroll**' option. When going over this limit, the first 10% of the scrolled lines are deleted and are lost.

Cursor style

terminal-cursor-style

By default the cursor in the terminal window uses a not blinking block. The normal xterm escape sequences can be used to change the blinking state and the shape. Once focus leaves the terminal window Vim will restore the original cursor.

An exception is when xterm is started with the "-bc" argument, or another way that causes the cursor to blink. This actually means that the blinking flag is inverted. Since Vim cannot detect this, the terminal window cursor blinking will also be inverted.

Session

terminal-session

A terminal window will be restored when using a session file, if possible and wanted.

If "terminal" was removed from '**sessionoptions**' then no terminal windows will be restored.

If the job in the terminal was finished the window will not be restored.

If the terminal can be restored, the command that was used to open it will be used again. To change this use the `term_setrestore()` function. This can

also be used to not restore a specific terminal by setting the command to "NONE".

Special keys

[terminal-special-keys](#)

Since the terminal emulator simulates an xterm, only escape sequences that both Vim and xterm recognize will be available in the terminal window. If you want to pass on other escape sequences to the job running in the terminal you need to set up forwarding. Example:

```
tmap <expr> <Esc>]b SendToTerm("\<Esc>]b")
func SendToTerm(what)
    call term_sendkeys(' ', a:what)
    return ''
endfunc
```

Unix

[terminal-unix](#)

On Unix a pty is used to make it possible to run all kinds of commands. You can even run Vim in the terminal! That's used for debugging, see below.

Environment variables are used to pass information to the running job:

| | |
|----------------|---|
| TERM | the name of the terminal, from the 'term' option or \$TERM in the GUI; falls back to "xterm" if it does not start with "xterm" |
| ROWS | number of rows in the terminal initially |
| LINES | same as ROWS |
| COLUMNS | number of columns in the terminal initially |
| COLORS | number of colors, 't_Co' (256*256*256 in the GUI) |
| VIM_SERVERNAME | v:servername |
| VIM_TERMINAL | v:version |

MS-Windows

[terminal-ms-windows](#)

On MS-Windows winpty is used to make it possible to run all kind of commands. Obviously, they must be commands that run in a terminal, not open their own window.

You need the following two files from winpty:

```
winpty.dll
winpty-agent.exe
```

You can download them from the following page:

<https://github.com/rprichard/winpty>

Just put the files somewhere in your PATH. You can set the **'winptydll'** option to point to the right file, if needed. If you have both the 32-bit and 64-bit version, rename to winpty32.dll and winpty64.dll to match the way Vim was build.

[ConPTY](#) [E982](#)

On more recent versions of MS-Windows 10 (beginning with the "October 2018 Update"), winpty is no longer required. On those versions, `:terminal` will use Windows' built-in support for hosting terminal applications, "ConPTY". When ConPTY is in use, there may be rendering artifacts regarding ambiguous-width characters. If you encounter any such issues, install "winpty". Until the ConPTY problems have been fixed "winpty" will be preferred.

Environment variables are used to pass information to the running job:
VIM_SERVERNAME v:servername

There exists a git-diff tool extension called `git-vimdumps` that can be used to conveniently inspect screendump files and diff them. Please see in the Vim Repository the file `src/testdir/commondumps.vim` on how to create and use this git extension.

2. Terminal functions

[terminal-function-details](#)

`term_dumpdiff({filename}, {filename} [, {options}])` [term_dumpdiff\(\)](#)
Open a new window displaying the difference between the two files. The files must have been created with `term_dumpwrite()`.
Returns the buffer number or zero when the diff fails.
Also see [terminal-diff](#).
NOTE: this does not work with double-width characters yet.

The top part of the buffer contains the contents of the first file, the bottom part of the buffer contains the contents of the second file. The middle part shows the differences. The parts are separated by a line of equals.

If the `{options}` argument is present, it must be a Dict with these possible members:

| | |
|-------------|---|
| "term_name" | name to use for the buffer name, instead of the first file name. |
| "term_rows" | vertical size to use for the terminal, instead of using <code>'termwinsize'</code> , but respecting the minimal size |
| "term_cols" | horizontal size to use for the terminal, instead of using <code>'termwinsize'</code> , but respecting the minimal size |
| "vertical" | split the window vertically |
| "curwin" | use the current window, do not split the window; fails if the current buffer cannot be abandoned |
| "bufnr" | do not create a new buffer, use the existing buffer "bufnr". This buffer must have been previously created with <code>term_dumpdiff()</code> or <code>term_dumpload()</code> and visible in a window. |
| "norestore" | do not add the terminal window to a session file |

Each character in the middle part indicates a difference. If there are multiple differences only the first in this list is used:

| | |
|---|--|
| X | different character |
| w | different width |
| f | different foreground color |
| b | different background color |
| a | different attribute |
| + | missing position in first file |
| - | missing position in second file |
| > | cursor position in first file, not in second |
| < | cursor position in second file, not in first |

Using the "s" key the top and bottom parts are swapped. This makes it easy to spot a difference.

Can also be used as a [method](#) :

```
GetFilename()->term_dumpdiff(otherfile)
```

Return type: [Number](#)

`term_dumpload({filename} [, {options}])` [term_dumpload\(\)](#)

Open a new window displaying the contents of `{filename}`. The file must have been created with [term_dumpwrite\(\)](#). Returns the buffer number or zero when it fails. Also see [terminal-diff](#).

For `{options}` see [term_dumpdiff\(\)](#).

Can also be used as a [method](#) :

```
GetFilename()->term_dumpload()
```

Return type: [Number](#)

`term_dumpwrite({buf}, {filename} [, {options}])` [term_dumpwrite\(\)](#)

Dump the contents of the terminal screen of `{buf}` in the file `{filename}`. This uses a format that can be used with [term_dumpload\(\)](#) and [term_dumpdiff\(\)](#).

If the job in the terminal already finished an error is given:

[E958](#)

If `{filename}` already exists an error is given: [E953](#)

Also see [terminal-diff](#).

`{options}` is a dictionary with these optional entries:

| | |
|-----------|-----------------------------------|
| "rows" | maximum number of rows to dump |
| "columns" | maximum number of columns to dump |

Can also be used as a [method](#), the base is used for the file name:

```
GetFilename()->term_dumpwrite(bufnr)
```

Return type: `Number`

`term_getaltscreen({buf})` `term_getaltscreen()`

Returns 1 if the terminal of `{buf}` is using the alternate screen.

`{buf}` is used as with `term_getsize()` .

Can also be used as a `method` :

`GetBufnr()->term_getaltscreen()`

Return type: `Number`

`term_getansicolors({buf})` `term_getansicolors()`

Get the ANSI color palette in use by terminal `{buf}`.

Returns a List of length 16 where each element is a String representing a color in hexadecimal "#rrggbb" format.

Also see `term_setansicolors()` and `g:terminal_ansi_colors` .

If neither was used returns the default colors.

`{buf}` is used as with `term_getsize()` . If the buffer does not exist or is not a terminal window, an empty list is returned.

Can also be used as a `method` :

`GetBufnr()->term_getansicolors()`

Return type: `list<string>` or `list<any>`

{only available when compiled with GUI enabled and/or the `+termguicolors` feature}

`term_getattr({attr}, {what})` `term_getattr()`

Given `{attr}`, a value returned by `term_scrape()` in the "attr" item, return whether `{what}` is on. `{what}` can be one of:

- `bold`
- `italic`
- `underline`
- `strike`
- `reverse`

Can also be used as a `method` :

`GetAttr()->term_getattr()`

Return type: `Number`

`term_getcursor({buf})` `term_getcursor()`

Get the cursor position of terminal `{buf}`. Returns a list with two numbers and a dictionary: `[row, col, dict]`.

"row" and "col" are one based, the first screen cell is row 1, column 1. This is the cursor position of the terminal itself, not of the Vim window.

"dict" can have these members:

- "visible" one when the cursor is visible, zero when it is hidden.
- "blink" one when the cursor is blinking, zero when it is not blinking.
- "shape" 1 for a block cursor, 2 for underline and 3 for a vertical bar.
- "color" color of the cursor, e.g. "green"

{buf} must be the buffer number of a terminal window. If the buffer does not exist or is not a terminal window, an empty list is returned.

Can also be used as a `method` :
`GetBufnr()->term_getcursor()`

Return type: `list<any>`

`term_getjob({buf})` `term_getjob()`
Get the Job associated with terminal window {buf}.
{buf} is used as with `term_getsize()` .
Returns `v:null` when there is no job. In Vim9 script, return `null_job` when there is no job.

Can also be used as a `method` :
`GetBufnr()->term_getjob()`

Return type: `job`

`term_getline({buf}, {row})` `term_getline()`
Get a line of text from the terminal window of {buf}.
{buf} is used as with `term_getsize()` .
The first line has {row} one. When {row} is "." the cursor line is used. When {row} is invalid an empty string is returned.

To get attributes of each character use `term_scrape()` .

Can also be used as a `method` :
`GetBufnr()->term_getline(row)`

Return type: `String`

`term_getscrolled({buf})` `term_getscrolled()`
Return the number of lines that scrolled to above the top of terminal {buf}. This is the offset between the row number used for `term_getline()` and `getline()` , so that:
`term_getline(buf, N)`
is equal to:

`getline(N + term_getscrolled(buf))`
(if that line exists).

`{buf}` is used as with `term_getsize()` .

Can also be used as a `method` :
`GetBufnr()->term_getscrolled()`

Return type: `Number`

`term_getsize({buf})` `term_getsize()`
Get the size of terminal `{buf}`. Returns a list with two numbers: [rows, cols]. This is the size of the terminal, not the window containing the terminal.

`{buf}` must be the buffer number of a terminal window. Use an empty string for the current buffer. If the buffer does not exist or is not a terminal window, an empty list is returned.

Can also be used as a `method` :
`GetBufnr()->term_getsize()`

Return type: `list<number>` or `list<any>`

`term_getstatus({buf})` `term_getstatus()`
Get the status of terminal `{buf}`. This returns a String with a comma-separated list of these items:
 running job is running
 finished job has finished
 normal in Terminal-Normal mode
One of "running" or "finished" is always present.

`{buf}` must be the buffer number of a terminal window. If the buffer does not exist or is not a terminal window, an empty string is returned.

Can also be used as a `method` :
`GetBufnr()->term_getstatus()`

Return type: `String`

`term_gettitle({buf})` `term_gettitle()`
Get the title of terminal `{buf}`. This is the title that the job in the terminal has set.

`{buf}` must be the buffer number of a terminal window. If the buffer does not exist or is not a terminal window, an empty string is returned.

Can also be used as a `method` :
`GetBufnr()->term_gettitle()`

Return type: `String`

`term_gettty({buf} [, {input}])` `term_gettty()`
Get the name of the controlling terminal associated with terminal window `{buf}`. `{buf}` is used as with `term_getsize()` .

When `{input}` is omitted or 0, return the name for writing (stdout). When `{input}` is 1 return the name for reading (stdin). On UNIX, both return same name.

Can also be used as a `method` :
`GetBufnr()->term_gettty()`

Return type: `String`

`term_list()` `term_list()`
Return a list with the buffer numbers of all buffers for terminal windows.

Return type: `list<number>` or `list<any>`

`term_scrape({buf}, {row})` `term_scrape()`
Get the contents of `{row}` of terminal screen of `{buf}`. For `{buf}` see `term_getsize()` .

The first line has `{row}` one. When `{row}` is "." the cursor line is used. When `{row}` is invalid an empty string is returned.

Return a List containing a Dict for each screen cell:

| | |
|---------|---|
| "chars" | character(s) at the cell |
| "fg" | foreground color as #rrggbb |
| "bg" | background color as #rrggbb |
| "attr" | attributes of the cell, use <code>term_getattr()</code> to get the individual flags |
| "width" | cell width: 1 or 2 |

For a double-width cell there is one item, thus the list can be shorter than the width of the terminal.

Can also be used as a `method` :
`GetBufnr()->term_scrape(row)`

Return type: `list<dict<any>>` or `list<any>`

`term_sendkeys({buf}, {keys})` `term_sendkeys()`
Send keystrokes `{keys}` to terminal `{buf}`. `{buf}` is used as with `term_getsize()` .

`{keys}` are translated as key sequences. For example, `"\<c-x>"`

means the character **CTRL-X**.

Can also be used as a `method` :
`GetBufnr()->term_sendkeys(keys)`

Return type: `Number`

`term_setansicolors({buf}, {colors})` `term_setansicolors()`
Set the ANSI color palette used by terminal `{buf}`.
`{colors}` must be a List of 16 valid color names or hexadecimal color codes, like those accepted by `highlight-guifg`.
Also see `term_getansicolors()` and `g:terminal_ansi_colors`.

The colors normally are:

| | |
|----|--------------|
| 0 | black |
| 1 | dark red |
| 2 | dark green |
| 3 | brown |
| 4 | dark blue |
| 5 | dark magenta |
| 6 | dark cyan |
| 7 | light grey |
| 8 | dark grey |
| 9 | red |
| 10 | green |
| 11 | yellow |
| 12 | blue |
| 13 | magenta |
| 14 | cyan |
| 15 | white |

These colors are used in the GUI and in the terminal when `'termguicolors'` is set. When not using GUI colors (GUI mode or `'termguicolors'`), the terminal window always uses the 16 ANSI colors of the underlying terminal.

Can also be used as a `method` :
`GetBufnr()->term_setansicolors(colors)`

Return type: `Number`

{only available with GUI enabled and/or the `+termguicolors` feature}

`term_setapi({buf}, {expr})` `term_setapi()`
Set the function name prefix to be used for the `terminal-api` function in terminal `{buf}`. For example:
`:call term_setapi(buf, "Myapi_")`
`:call term_setapi(buf, "")`

The default is `"Tapi_"`. When `{expr}` is an empty string then no `terminal-api` function can be used for `{buf}`.

When used as a method the base is used for `{buf}`:
`GetBufnr()->term_setapi({expr})`

Return type: `Number`

`term_setkill({buf}, {how})` `term_setkill()`

When exiting Vim or trying to close the terminal window in another way, `{how}` defines whether the job in the terminal can be stopped.

When `{how}` is empty (the default), the job will not be stopped, trying to exit will result in `E947`. Otherwise, `{how}` specifies what signal to send to the job. See `job_stop()` for the values.

After sending the signal Vim will wait for up to a second to check that the job actually stopped.

Can also be used as a `method` :
`GetBufnr()->term_setkill(how)`

Return type: `Number`

`term_setrestore({buf}, {command})` `term_setrestore()`

Set the command to write in a session file to restore the job in this terminal. The line written in the session file is:

```
terminal ++curwin ++cols=%d ++rows=%d {command}
```

Make sure to escape the command properly.

Use an empty `{command}` to run `'shell'`.
Use `"NONE"` to not restore this window.

Can also be used as a `method` :
`GetBufnr()->term_setrestore(command)`

Return type: `Number`

`term_setsize({buf}, {rows}, {cols})` `term_setsize()` `E955`

Set the size of terminal `{buf}`. The size of the window containing the terminal will also be adjusted, if possible. If `{rows}` or `{cols}` is zero or negative, that dimension is not changed.

`{buf}` must be the buffer number of a terminal window. Use an empty string for the current buffer. If the buffer does not exist or is not a terminal window, an error is given.

Can also be used as a `method` :
`GetBufnr()->term_setsize(rows, cols)`

Return type: `Number`

`term_start({cmd} [, {options}])` `term_start()`
Open a terminal window and run `{cmd}` in it.

`{cmd}` can be a string or a List, like with `job_start()`. The string "NONE" can be used to open a terminal window without starting a job, the pty of the terminal can be used by a command like `gdb`.

Returns the buffer number of the terminal window. If `{cmd}` cannot be executed the window does open and shows an error message.

If opening the window fails zero is returned.

`{options}` are similar to what is used for `job_start()`, see `job-options`. However, not all options can be used. These are supported:

all timeout options

"stoponexit", "cwd", "env"

"callback", "out_cb", "err_cb", "exit_cb", "close_cb"

"in_io", "in_top", "in_bot", "in_name", "in_buf"

"out_io", "out_name", "out_buf", "out_modifiable", "out_msg"

"err_io", "err_name", "err_buf", "err_modifiable", "err_msg"

However, at least one of `stdin`, `stdout` or `stderr` must be connected to the terminal. When I/O is connected to the terminal then the callback function for that part is not used.

There are extra options:

"term_name" name to use for the buffer name, instead of the command name.

"term_rows" vertical size to use for the terminal, instead of using `'termwinsize'`; valid range is from zero to 1000

"term_cols" horizontal size to use for the terminal, instead of using `'termwinsize'`

"vertical" split the window vertically; `note` that other window position can be defined with command modifiers, such as `:belowright`.

"curwin" use the current window, do not split the window; fails if the current buffer cannot be abandoned

"hidden" do not open a window

"norestore" do not add the terminal window to a session file

"term_kill" what to do when trying to close the terminal window, see `term_setkill()`

"term_finish" What to do when the job is finished:

"close": close any windows

"open": open window if needed

`Note` that "open" can be interruptive.

See `term++close` and `term++open`.

"term_opencmd" command to use for opening the window when "open" is used for "term_finish"; must

| | |
|-----------------------------|--|
| <pre>"term_highlight"</pre> | <pre>have "%d" where the buffer number goes, e.g. "10split buffer %d"; when not specified "botright sbuf %d" is used highlight group to use instead of "Terminal"</pre> |
| <pre>"eof_chars"</pre> | <pre>Text to send after all buffer lines were written to the terminal. When not set CTRL-D is used on MS-Windows. For Python use CTRL-Z or "exit()". For a shell use "exit". A CR is always added.</pre> |
| <pre>"ansi_colors"</pre> | <pre>A list of 16 color names or hex codes defining the ANSI palette used in GUI color modes. See g:terminal_ansi_colors .</pre> |
| <pre>"tty_type"</pre> | <pre>(MS-Windows only): Specify which pty to use. See 'termwintype' for the values.</pre> |
| <pre>"term_api"</pre> | <pre>function name prefix for the terminal-api function. See term_setapi() .</pre> |

Can also be used as a [method](#) :
[GetCommand\(\)->term_start\(\)](#)

Return type: [Number](#)

`term_wait({buf} [, {time}])` [term_wait\(\)](#)

Wait for pending updates of `{buf}` to be handled.
`{buf}` is used as with [term_getsize\(\)](#) .
`{time}` is how long to wait for updates to arrive in msec. If
not set then 10 msec will be used. Queued messages will also
be processed similar to `:sleep` .

Can also be used as a [method](#) :
[GetBufnr\(\)->term_wait\(\)](#)

Return type: [Number](#)

3. Terminal communication [terminal-communication](#)

- There are several ways to communicate with the job running in a terminal:
- Use [term_sendkeys\(\)](#) to send text and escape sequences from Vim to the job.
 - Use the JSON API to send encoded commands from the job to Vim.
 - Use the [client-server](#) mechanism. This works on machines with an X server and on MS-Windows.

[Vim to job: term_sendkeys\(\)](#) [terminal-to-job](#)

This allows for remote controlling the job running in the terminal. It is a one-way mechanism. The job can update the display to signal back to Vim. For example, if a shell is running in a terminal, you can do:

```
call term_sendkeys(buf, "ls *.java<CR>")
```

This requires for the job to be in the right state where it will do the right thing when receiving the keys. For the above example, the shell must be waiting for a command to be typed.

For a job that was written for the purpose, you can use the JSON API escape sequence in the other direction. E.g.:

```
call term_sendkeys(buf, "\<Esc>]51;[\"response\"]\x07")
```

Job to Vim: JSON API

terminal-api

The job can send JSON to Vim, using a special escape sequence. The JSON encodes a command that Vim understands. Example of such a message:

```
<Esc>]51;[\"drop\", \"README.md\"]<07>
```

The body is always a list, making it easy to find the end:]<07>.

The <Esc>]51;msg<07> sequence is reserved by xterm for "Emacs shell", which is similar to what we are doing here.

Currently supported commands:

```
call {funcname} {argument}
```

Call a user defined function with {argument}.

The function is called with two arguments: the buffer number of the terminal and {argument}, the decoded JSON argument.

By default, the function name must start with "Tapi_" to avoid accidentally calling a function not meant to be used for the terminal API. This can be changed with `term_setapi()`.

The user function should sanity check the argument.

The function can use `term_sendkeys()` to send back a reply.

Example in JSON:

```
[\"call\", \"Tapi_Impression\", [\"play\", 14]]
```

Calls a function defined like this:

```
function Tapi_Impression(bufnum, arglist)
  if len(a:arglist) == 2
    echomsg \"impression \" .. a:arglist[0]
    echomsg \"count \" .. a:arglist[1]
  endif
endfunc
```

Output from `:echo` may be erased by a redraw, use `:echomsg` to be able to see it with `:messages`.

```
drop {filename} [options]
```

Let Vim open a file, like the `:drop` command. If {filename} is already open in a window, switch to that window. Otherwise open a new window to edit {filename}.

Note that both the job and Vim may change the current directory, thus it's best to use the full path.

[options] is only used when opening a new window. If present, it must be a Dict. Similarly to `++opt`, these entries are recognized:

```

"ff"          file format: "dos", "mac" or "unix"
"fileformat" idem
"enc"        overrides 'fileencoding'
"encoding"   idem
"bin"        sets 'binary'
"binary"     idem
"nobin"      resets 'binary'
"nobinary"   idem
"bad"        specifies behavior for bad characters, see
              ++bad

```

Example in JSON:

```
["drop", "path/file.txt", {"ff": "dos"}]
```

You can use `echoraw()` to make Vim send this escape sequence:

```
call echoraw("\<ESC>]51;[\"call\", \"Tapi_TryThis\", [\"hello\", 123]]\x07")
call echoraw("\<Esc>]51;[\"drop\", \"README.md\"]\x07")
```

Note: JSON requires double quotes around string values, hence those have to be escaped.

Rationale: Why not allow for any command or expression? Because that might create a security problem.

`terminal-autoshelldir`

This can be used to pass the current directory from a shell to Vim.

Put this in your `.vimrc`:

```
def g:Tapi_lcd(_, path: string)
  if isdirectory(path)
    execute 'silent lcd ' .. fnameescape(path)
  endif
enddef
```

And, in a bash init file:

```
if [[ -n "$VIM_TERMINAL" ]]; then
  PROMPT_COMMAND='_vim_sync_PWD'
  function _vim_sync_PWD() {
    printf '\033]51;["call", "Tapi_lcd", "%q"]\007' "$PWD"
  }
fi
```

Or, for zsh:

```
if [[ -n "$VIM_TERMINAL" ]]; then
  autoload -Uz add-zsh-hook
  add-zsh-hook -Uz chpwd _vim_sync_PWD
  function _vim_sync_PWD() {
    printf '\033]51;["call", "Tapi_lcd", "%q"]\007' "$PWD"
  }
fi
```

Or, for fish:

```
if test -n "$VIM_TERMINAL"
  function _vim_sync_PWD --on-variable=PWD
    printf '\033]51;["call", "Tapi_lcd", "%s"]\007' "$PWD"
  end
end
```

Using the client-server feature

terminal-client-server

This only works when `v:servername` is not empty. If needed you can set it, before opening the terminal, with:

```
call remote_startserver('vim-server')
```

`$VIM_SERVERNAME` is set in the terminal to pass on the server name.

In the job you can then do something like:

```
vim --servername $VIM_SERVERNAME --remote +123 some_file.c
```

This will open the file "some_file.c" and put the cursor on line 123.

4. Remote testing

terminal-testing

Most Vim tests execute a script inside Vim. For some tests this does not work, running the test interferes with the code being tested. To avoid this Vim is executed in a terminal window. The test sends keystrokes to it and inspects the resulting screen state.

Functions

| | |
|------------------------------|---|
| <code>term_sendkeys()</code> | send keystrokes to a terminal (not subject to tmap) |
| <code>term_wait()</code> | wait for screen to be updated |
| <code>term_scrape()</code> | inspect terminal screen |

5. Diffing screen dumps

terminal-diff

In some cases it can be bothersome to test that Vim displays the right characters on the screen. E.g. with syntax highlighting. To make this simpler it is possible to take a screen dump of a terminal and compare it to an expected screen dump.

Vim uses the window size, text, color and other attributes as displayed. The Vim screen size, font and other properties do not matter. Therefore this mechanism is portable across systems. A conventional screenshot would reflect all differences, including font size and family.

Writing a screen dump test for Vim

terminal-dumptest

For an example see the `Test_syntax_c()` function in `src/testdir/test_syntax.vim`. The main parts are:

- Write a file you want to test with. This is useful for testing syntax highlighting. You can also start Vim with an empty buffer.
- Run Vim in a terminal with a specific size. The default is 20 lines of 75 characters. This makes sure the dump is always this size. The function `RunVimInTerminal()` takes care of this. Pass it the arguments for the Vim command.
- Send any commands to Vim using `term_sendkeys()`. For example:

- ```
call term_sendkeys(buf, ":echo &lines &columns\<CR>")
```
- Check that the screen is now in the expected state, using `VerifyScreenDump()`. This expects the reference screen dump to be in the `src/testdir/dumps/` directory. Pass the name without `".dump"`. It is recommended to use the name of the test function and a sequence number, so that we know what test is using the file.
  - Repeat sending commands and checking the state.
  - Finally stop Vim by calling `StopVimInTerminal()`.

The first time you do this you won't have a screen dump yet. Create an empty file for now, e.g.:

```
touch src/testdir/dumps/Test_function_name_01.dump
```

The test will then fail, giving you the command to compare the reference dump and the failed dump, e.g.:

```
call term_dumpdiff("failed/Test_func.dump", "dumps/Test_func.dump")
```

Use this command in Vim, with the current directory set to `src/testdir`. Once you are satisfied with the test, move the failed dump in place of the reference:

```
:!mv failed/Test_func.dump dumps/Test_func.dump
```

## Creating a screen dump

`terminal-screendump`

To create the screen dump, run Vim (or any other program) in a terminal and make it show the desired state. Then use the `term_dumpwrite()` function to create a screen dump file. For example:

```
:call term_dumpwrite(77, "mysyntax.dump")
```

Here "77" is the buffer number of the terminal. Use ``:ls!`` to see it.

You can view the screen dump with `term_dumpload()` :

```
:call term_dumpload("mysyntax.dump")
```

To verify that Vim still shows exactly the same screen, run Vim again with exactly the same way to show the desired state. Then create a screen dump again, using a different file name:

```
:call term_dumpwrite(88, "test.dump")
```

To assert that the files are exactly the same use `assert_equalfile()` :

```
call assert_equalfile("mysyntax.dump", "test.dump")
```

If there are differences then `v:errors` will contain the error message.

## Comparing screen dumps

`terminal-diffscreeendump`

`assert_equalfile()` does not make it easy to see what is different.

To spot the problem use `term_dumpdiff()` :

```
call term_dumpdiff("mysyntax.dump", "test.dump")
```

This will open a window consisting of three parts:

1. The contents of the first dump

2. The difference between the first and second dump
3. The contents of the second dump

You can usually see what differs in the second part. Use the **'ruler'** to relate it to the position in the first or second dump. Letters indicate the kind of difference:

```

X different character
> cursor in first but not in second
< cursor in second but not in first
w character width differs (single vs double width)
f foreground color differs
b background color differs
a attribute differs (bold, underline, reverse, etc.)
? character missing in both
+ character missing in first
- character missing in second

```

Alternatively, press "s" to swap the first and second dump. Do this several times so that you can spot the difference in the context of the text.

=====

6. Debugging      [terminal-debug](#)    [terminal-debugger](#)    [package-termdebug](#)

The Terminal debugging plugin can be used to debug a program with gdb and view the source code in a Vim window. Since this is completely contained inside Vim this also works remotely over an ssh connection.

When the [+terminal](#) feature is missing, the plugin will use the "prompt" buffer type, if possible. The running program will then use a newly opened terminal window. See [termdebug-prompt](#) below for details.

## Starting

[termdebug-starting](#)

Load the plugin with this command:

```
packadd termdebug
```

When loading the plugin from the `.vimrc` file, add the "!" attribute:

```
packadd! termdebug
```

[:Termdebug](#)

To start debugging use ``:Termdebug`` or ``:TermdebugCommand`` followed by the command name, for example:

```
:Termdebug vim
```

This opens two windows:

**gdb window**      A terminal window in which "gdb vim" is executed. Here you can directly interact with gdb. The buffer name is "!gdb".

**program window**    A terminal window for the executed program. When "run" is used in gdb the program I/O will happen in this window, so that it does not interfere with controlling gdb. The buffer name is "debugged program".

The current window is used to show the source code. When gdb pauses the

source file location will be displayed, if possible. A sign is used to highlight the current position, using highlight group debugPC.

If the buffer in the current window is modified, another window will be opened to display the current gdb position. You can use `:Winbar` to add a window toolbar there.

Focus the terminal of the executed program to interact with it. This works the same as any command running in a terminal window.

When the debugger ends, typically by typing "quit" in the gdb window, the two opened windows are closed.

Only one debugger can be active at a time.

#### termdebug-timeout

Depending on how gdb is launched, termdebug startup time may vary. To avoid termdebug to get stuck if the startup process of gdb takes too long, a configurable timeout is included. Such time out is configurable in terms of multiple of 10ms:

```
let g:termdebug_config['timeout'] = 500 # 500 * 10ms = 5 seconds.
```

The default timeout is 3000 ms.

#### :TermdebugCommand

If you want to give specific commands to the command being debugged, you can use the `:TermdebugCommand` command followed by the command name and additional parameters.

```
:TermdebugCommand vim --clean -c ':set nu'
```

Both the `:Termdebug` and `:TermdebugCommand` support an optional "!" bang argument to start the command right away, without pausing at the gdb window (and cursor will be in the debugged window). For example:

```
:TermdebugCommand! vim --clean
```

To attach gdb to an already running executable or use a core file, pass extra arguments. E.g.:

```
:Termdebug vim core
:Termdebug vim 98343
```

If no argument is given, you'll end up in a gdb window, in which you need to specify which command to run using e.g. the gdb `file` command.

### Example session

#### termdebug-example

Start in the Vim "src" directory and build Vim:

```
% make
```

Make sure that debug symbols are present, usually that means that `$CFLAGS` includes `"-g"`.

Start Vim:

```
% ./vim
```

Load the termdebug plugin and start debugging Vim:

```
:packadd termdebug
:Termdebug vim
```

You should now have three windows:

- source - where you started, has a window toolbar with buttons
- gdb - you can type gdb commands here
- program - the executed program will use this window

You can use **CTRL-W CTRL-W** or the mouse to move focus between windows.

Put focus on the gdb window and type:

```
break ex_help
run
```

Vim will start running in the program window. Put focus there and type:

```
:help gui
```

Gdb will run into the ex\_help breakpoint. The source window now shows the ex\_cmds.c file. A red "1" marker will appear in the signcolumn where the breakpoint was set. The line where the debugger stopped is highlighted. You can now step through the program. Let's use the mouse: click on the "Next" button in the window toolbar. You will see the highlighting move as the debugger executes a line of source code.

Click "Next" a few times until the for loop is highlighted. Put the cursor on the end of "eap->arg", then click "Eval" in the toolbar. You will see this displayed:

```
"eap->arg": 0x555555e68855 "gui"
```

This way you can inspect the value of local variables. You can also focus the gdb window and use a "print" command, e.g.:

```
print *eap
```

If mouse pointer movements are working, Vim will also show a balloon when the mouse rests on text that can be evaluated by gdb.

Now go back to the source window and put the cursor on the first line after the for loop, then type:

```
:Break
```

You will see a ">>" marker appear, this indicates the new breakpoint. Now click "Cont" in the toolbar and the code until the breakpoint will be executed.

You can type more advanced commands in the gdb window. For example, type:

```
watch curbuf
```

Now click "Cont" in the toolbar (or type "cont" in the gdb window). Execution will now continue until the value of "curbuf" changes, which is in do\_ecmd(). To remove this watchpoint again type in the gdb window:

```
delete 3
```

You can see the stack by typing in the gdb window:

```
where
```

Move through the stack frames, e.g. with:

```
frame 3
```

The source window will show the code, at the point where the call was made to a deeper level.

Stepping through code

termdebug-stepping

Put focus on the gdb window to type commands there. Some common ones are:

- **CTRL-C** interrupt the program
- next execute the current line and stop at the next line
- step execute the current line and stop at the next statement, entering functions
- until execute until past the current cursor line or past a specified position or the current stack frame returns
- finish execute until leaving the current function
- where show the stack
- frame N go to the Nth stack frame
- continue continue execution

**:Run** **:Arguments**

In the window showing the source code these commands can be used to control gdb:

**:Run** [args] run the program with [args] or the previous arguments  
**:Arguments** {args} set arguments for the next **:Run**

**:Break** set a breakpoint at the cursor position  
**:Break** {position}

set a breakpoint at the specified position  
**:Tbreak** set a temporary breakpoint at the cursor position  
**:Tbreak** {position}

set a temporary breakpoint at the specified position  
**:Clear** delete the breakpoint at the cursor position

**:Step** execute the gdb "step" command  
**:Over** execute the gdb "next" command (**:Next** is a Vim command)  
**:Until** execute the gdb "until" command  
**:Finish** execute the gdb "finish" command  
**:Continue** execute the gdb "continue" command  
**:Stop** interrupt the program

If **'mouse'** is set the plugin adds a window toolbar with these entries:

Step **:Step**  
Next **:Over**  
Finish **:Finish**  
Cont **:Continue**  
Stop **:Stop**  
Eval **:Evaluate**

This way you can use the mouse to perform the most common commands. You need to have the **'mouse'** option set to enable mouse clicks.

See [termdebug\\_winbar](#) for configuring this toolbar.

**:Winbar**

You can add the window toolbar in other windows you open with:

**:Winbar**

If gdb stops at a source line and there is no window currently showing the source code, a new window will be created for the source code. This also happens if the buffer in the source code window has been modified and can't be abandoned.

Gdb gives each breakpoint a number. In Vim the number shows up in the sign column, with a red background. You can use these gdb commands:

- info break list breakpoints
  - delete N delete breakpoint N
- You can also use the `:Clear` command if the cursor is in the line with the breakpoint, or use the "Clear breakpoint" right-click menu entry.

## Inspecting variables

termdebug-variables :Evaluate

```

:Evaluate` evaluate the expression under the cursor
`K` same (see termdebug_map_K to disable)
:Evaluate` {expr} evaluate {expr}
`:'<,'>Evaluate` evaluate the Visually selected text

```

This is similar to using "print" in the gdb window.  
You can usually shorten `:Evaluate` to `:Ev`.

## Navigating stack frames

termdebug-frames :Frame :Up :Down

```

:Frame` [frame] select frame [frame], which is a frame number,
address, or function name (default: current frame)
:Up` [count] go up [count] frames (default: 1; the frame that
called the current)
`+` same (see termdebug_map_plus to disable)
:Down` [count] go down [count] frames (default: 1; the frame called
by the current)
`-` same (see termdebug_map_minus to disable)

```

## Other commands

termdebug-commands

```

:Gdb jump to the gdb window
:Program jump to the window with the running program
:Source jump to the window with the source code, create it if there
isn't one
:Asm jump to the window with the disassembly, create it if there
isn't one
:Var jump to the window with the local and argument variables,
create it if there isn't one. This window updates whenever the
program is stopped

```

## Events

termdebug-events

Four autocommands can be used:

```

au User TermdebugStartPre echomsg 'debugging starting'
au User TermdebugStartPost echomsg 'debugging started'
au User TermdebugStopPre echomsg 'debugging stopping'
au User TermdebugStopPost echomsg 'debugging stopped'

```

TermdebugStartPre

TermdebugStartPre Before starting debugging.  
Not triggered if the debugger is already running or the debugger command cannot be executed.

TermdebugStartPost	<p style="text-align: right;"><b>TermdebugStartPost</b></p> <p>After debugging has initialized. If a "!" bang is passed to <code>`:Termdebug`</code> or <code>`:TermdebugCommand`</code> the event is triggered before running the provided command in gdb.</p>
TermdebugStopPre	<p style="text-align: right;"><b>TermdebugStopPre</b></p> <p>Before debugging ends, when gdb is terminated, most likely after issuing a "quit" command in the gdb window.</p>
TermdebugStopPost	<p style="text-align: right;"><b>TermdebugStopPost</b></p> <p>After debugging has ended, gdb-related windows are closed, debug buffers wiped out and the state before the debugging was restored.</p>

## Customizing

**termdebug-customizing**    **g:termdebug\_config**

In the past several global variables were used for configuration. These are deprecated and using the `g:termdebug_config` dictionary is preferred. When `g:termdebug_config` exists the other global variables will NOT be used. The recommended way is to start with an empty dictionary:

```
let g:termdebug_config = {}
```

Then you can add entries to the dictionary as mentioned below. The deprecated global variable names are mentioned for completeness. If you are switching over to using `g:termdebug_config` you can find the old variable name and take over the value, then delete the deprecated variable.

## Prompt mode

**termdebug-prompt**

When the `+terminal` feature is not supported and on MS-Windows, gdb will run in a buffer with `'buftype'` set to "prompt". This works slightly differently:

- The gdb window will be in Insert mode while typing commands. Go to Normal mode with `<Esc>`, then you can move around in the buffer, copy/paste, etc. Go back to editing the gdb command with any command that starts Insert mode, such as ``a`` or ``i``.
- The program being debugged will run in a separate window. On MS-Windows this is a new console window. On Unix, if the `+terminal` feature is available a Terminal window will be opened to run the debugged program in.

**termdebug\_use\_prompt**

Prompt mode can be used even when the `+terminal` feature is present with:

```
let g:termdebug_config['use_prompt'] = v:true
```

If there is no `g:termdebug_config` you can use:

```
let g:termdebug_use_prompt = v:true
```

However, the latter form will be deprecated in future releases.

## Mappings

The `termdebug` plugin enables a few default mappings. All those mappings are reset to their original values once the `termdebug` session concludes.

The K key is normally mapped to `:Evaluate` unless a buffer local (`:map-local`) mapping to K already exists. If you do not want this use:

```
let g:termdebug_map_K = v:false
```

If there is no `g:termdebug_config` you can use:

```
let g:termdebug_map_K = v:false
```

However, the latter form will be deprecated in future releases.

The - key is normally mapped to `:Down` unless a buffer local mapping to the - key already exists. If you do not want this use:

```
let g:termdebug_config['map_minus'] = v:false
```

The + key is normally mapped to `:Up` unless a buffer local mapping to the + key already exists. If you do not want this use:

```
let g:termdebug_config['map_plus'] = v:false
```

If you want the Asm window shown by default, set the "disasm\_window" flag to 1. The "disasm\_window\_height" entry can be used to set the window height:

```
let g:termdebug_config['disasm_window'] = v:true
let g:termdebug_config['disasm_window_height'] = 15
```

If there is no `g:termdebug_config` you can use:

```
let g:termdebug_disasm_window = 15
```

However, the latter form will be deprecated in future releases.

Any value greater than 1 will set the Asm window height to that value. If the current window has enough horizontal space, it will be vertically split and the Asm window will be shown side by side with the source code window (and the height option won't be used).

If you want the Var window shown by default, set the "variables\_window" flag to 1. The "variables\_window\_height" entry can be used to set the window height:

```
let g:termdebug_config['variables_window'] = v:true
let g:termdebug_config['variables_window_height'] = 15
```

If there is no `g:termdebug_config` you can use:

```
let g:termdebug_variables_window = 15
```

However, the latter form will be deprecated in future releases.

Any value greater than 1 will set the Var window height to that value. If the current window has enough horizontal space, it will be vertically split and the Var window will be shown side by side with the source code window (and the height options won't be used).

## Communication

`termdebug-communication`

There is another, hidden, buffer, which is used for Vim to communicate with gdb. The buffer name is "gdb communication". Do not delete this buffer, it will break the debugger.

Gdb has some weird behavior, the plugin does its best to work around that. For example, after typing "continue" in the gdb window a **CTRL-C** can be used to interrupt the running program. But after using the MI command "-exec-continue" pressing **CTRL-C** does not interrupt. Therefore you will see "continue" being used for the ``:Continue`` command, instead of using the communication channel.

## GDB command

`g:termdebugger`

To change the name of the gdb command, set "debugger" entry in `g:termdebug_config` or the "g:termdebugger" variable before invoking ``:Termdebug``:

```
let g:termdebug_config['command'] = "mygdb"
```

If there is no `g:termdebug_config` you can use:

```
let g:termdebugger = "mygdb"
```

However, the latter form will be deprecated in future releases.

If the command needs an argument use a List:

```
let g:termdebug_config['command'] = ['rr', 'replay', '--']
```

If there is no `g:termdebug_config` you can use:

```
let g:termdebugger = ['rr', 'replay', '--']
```

Several arguments will be added to make gdb work well for the debugger.

If you want to modify them, add a function to filter the argument list:

```
let g:termdebug_config['command_filter'] = MyDebugFilter
```

If you do not want the arguments to be added, but you do need to set the "pty", use a function to add the necessary arguments:

```
let g:termdebug_config['command_add_args'] = MyAddArguments
```

The function will be called with the list of arguments so far, and a second argument that is the name of the pty.

`gdb-version`

Only debuggers fully compatible with gdb will work. Vim uses the GDB/MI interface. The "new-ui" command requires gdb version 7.12 or later. If you get this error:

```
Undefined command: "new-ui". Try "help".
```

Then your gdb is too old.

## Colors

`hl-debugPC` `hl-debugBreakpoint`

The color of the signs can be adjusted with these highlight groups:

- debugPC the current position
- debugBreakpoint a breakpoint

The defaults are, when `'background'` is "light":

```
hi debugPC term=reverse ctermbg=lightblue guibg=lightblue
hi debugBreakpoint term=reverse ctermbg=red guibg=red
```

When **'background'** is "dark":

```
hi debugPC term=reverse ctermbg=darkblue guibg=darkblue
hi debugBreakpoint term=reverse ctermbg=red guibg=red
```

## Shortcuts

[termdebug\\_shortcuts](#)

You can define your own shortcuts (mappings) to control gdb, that can work in any window, using the `TermDebugSendCommand()` function. Example:

```
map ,w :call TermDebugSendCommand('where')<CR>
```

The argument is the gdb command.

## Popup menu

[termdebug\\_popup](#)

By default the Termdebug plugin sets **'mousemodel'** to "popup\_setpos" and adds these entries to the popup menu:

```
Set breakpoint `:Break`
Clear breakpoint `:Clear`
Evaluate `:Evaluate`
```

If you don't want this then disable it with:

```
let g:termdebug_config['popup'] = 0
```

If there is no `g:termdebug_config` you can use:

```
let g:termdebug_popup = 0
```

However, the latter form will be deprecated in future releases.

## Change default signs

[termdebug\\_signs](#)

Termdebug uses the hex number of the breakpoint ID in the signcolumn to represent breakpoints. If it is greater than "0xFF", then it will be displayed as "F+", due to we really only have two screen cells for the sign.

You may also use decimal breakpoint signs instead, in which case IDs greater than 99 will be displayed as "9+".

If you want to customize the breakpoint signs to show '>>' in the signcolumn:

```
let g:termdebug_config['sign'] = '>>'
```

If you would like to use decimal (base 10) breakpoint signs:

```
let g:termdebug_config['sign_decimal'] = 1
```

If the variable `g:termdebug_config` does not yet exist, you can use:

```
let g:termdebug_config = {'sign': '>>'}
```

Likewise, to enable decimal signs:

```
let g:termdebug_config = {'sign_decimal': 1}
```

## Window toolbar

[termdebug\\_winbar](#)

By default the Termdebug plugin creates a window toolbar if the mouse is enabled (see `:Winbar`). If you don't want this then disable it with:

```
let g:termdebug_config['winbar'] = 0
```

## Vim window width

`termdebug_wide`

To change the width of the Vim window when debugging starts and use a vertical split:

```
let g:termdebug_config['wide'] = 163
```

If there is no `g:termdebug_config` you can use:

```
let g:termdebug_wide = 163
```

However, the latter form will be deprecated in future releases.

This will set `'columns'` to 163 when ``:Termdebug`` is used. The value is restored when quitting the debugger.

If the wide value is set and `'columns'` is already a greater value, then a vertical split will be used without modifying `'columns'`.

Set the wide value to 1 to use a vertical split without ever changing `'columns'`. This is useful when the terminal can't be resized by Vim.

## Evaluate in Popup Window at Cursor

`termdebug_evaluate_in_popup`

By default `:Evaluate` will simply echo its output. For larger entities this might become difficult to read or even truncated.

Alternatively, the evaluation result may be output into a popup window at the current cursor position:

```
let g:termdebug_config['evaluate_in_popup'] = v:true
```

This can also be used in a "one-shot" manner:

```
func OnCursorHold()
 let g:termdebug_config['evaluate_in_popup'] = v:true
 :Evaluate
 let g:termdebug_config['evaluate_in_popup'] = v:false
endfunc
```

## Contributing

`termdebug_contributing`

Contributions for `termdebug` improvements are welcome.

However, it is fairly common that during the development process you need some mechanisms like ``echo`` statements (or similar) to help you in your job.

For this reason, you can set:

```
let g:termdebug_config['debug'] = true
```

This sets the ``DEBUG`` variable to ``true``, which can be referenced in the source code. An example of its usage follows:

```
if exists('g:termdebug_loaded')
 if DEBUG
 Echoerr('Termdebug already loaded.')
 endif
 finish
endif
```

=====

## 1. Introduction

[popup-intro](#)

We are talking about popup windows here, text that goes on top of the regular windows and is under control of a plugin. You cannot edit the text in the popup window like with regular windows.

A popup window can be used for such things as:

- briefly show a message without overwriting the command line
- prompt the user with a dialog
- display contextual information while typing
- give extra information for auto-completion

The text in the popup window can be colored with [text-properties](#) . It is also possible to use syntax highlighting.

The default color used is "Pmenu". If you prefer something else use the "highlight" argument or the **'wincolor'** option, e.g.:

```
hi MyPopupColor ctermbg=lightblue guibg=lightblue
call setwinvar(winid, '&wincolor', 'MyPopupColor')
```

**'hlsearch'** highlighting is not displayed in a popup window.

A popup window has a window-ID like other windows, but behaves differently. The size can be up to the whole Vim window and it overlaps other windows.

Popup windows can also overlap each other. The "zindex" property specifies what goes on top of what.

E366

The popup window contains a buffer, and that buffer is always associated with the popup window. The window cannot be in Normal, Visual or Insert mode, it does not get keyboard focus. You can use functions like ``setbufline()`` to change the text in the buffer. There are more differences from how this window and buffer behave compared to regular windows and buffers, see [popup-buffer](#) .

If this is not what you are looking for, check out other popup functionality:

- popup menu, see [popup-menu](#)
- balloon, see [balloon-eval](#)

## WINDOW POSITION AND SIZE

[popup-position](#)

The height of the window is normally equal to the number of, possibly wrapping, lines in the buffer. It can be limited with the "maxheight" property. You can use empty lines to increase the height or the "minheight" property.

The width of the window is normally equal to the longest visible line in the buffer. It can be limited with the "maxwidth" property. You can use spaces to increase the width or use the "minwidth" property.

By default the `'wrap'` option is set, so that no text disappears. Otherwise, if there is not enough space then the window is shifted left in order to display more text. When right-aligned the window is shifted right to display more text. The shifting can be disabled with the "fixed" property.

Vim tries to show the popup in the location you specify. In some cases, e.g. when the popup would go outside of the Vim window, it will show it somewhere nearby. E.g. if you use ``popup_atcursor()`` the popup normally shows just above the current cursor position, but if the cursor is close to the top of the Vim window it will be placed below the cursor position.

When the screen scrolls up for output of an Ex command, popups move too, so that they will not cover the output.

The current cursor position is displayed even when it is under a popup window. That way you can still see where it is, even though you cannot see the text that it is in.

## CLOSING THE POPUP WINDOW

[popup-close](#)

Normally the plugin that created the popup window is also in charge of closing it. If somehow a popup hangs around, you can close all of them with:

```
call popup_clear(1)
```

Some popups, such as notifications, close after a specified time. This can be set with the "time" property on ``popup_create()``.

Otherwise, a popup can be closed by clicking on the X in the top-right corner or by clicking anywhere inside the popup. This must be enabled with the

"close" property. It is set by default for notifications.

## POPUP BUFFER AND WINDOW

popup-buffer

If a popup function is called to create a popup from text, a new buffer is created to hold the text and text properties of the popup window. The buffer is always associated with the popup window and manipulation is restricted:

- the buffer has no name
- **'buftype'** is "popup"
- **'swapfile'** is off
- **'bufhidden'** is "hide"
- **'buflisted'** is off
- **'undolevels'** is -1: no undo at all
- all other buffer-local and window-local options are set to their Vim default value.

It is possible to change the specifically mentioned options, but anything might break then, so better leave them alone.

The window does have a cursor position, but the cursor is not displayed. In fact, the cursor in the underlying window is displayed, as if it peeks through the popup, so you can see where it is.

To execute a command in the context of the popup window and buffer use ``win_execute()``. Example:  
`call win_execute(winid, 'syntax enable')`

Options can be set on the window with ``setwinvar()``, e.g.:  
`call setwinvar(winid, '&wrap', 0)`

And options can be set on the buffer with ``setbufvar()``, e.g.:  
`call setbufvar(winbufnr(winid), '&filetype', 'java')`

You can also use ``win_execute()`` with a `":setlocal"` command.

## TERMINAL IN POPUP WINDOW

popup-terminal

A special case is running a terminal in a popup window. Many rules are then different:

- The popup window always has focus, it is not possible to switch to another window.
- When the job ends, the popup window shows the buffer in Terminal-Normal mode. Use ``:q`` to close it or use "term\_finish" value "close".
- The popup window can be closed with ``popup_close()``, the terminal buffer then becomes hidden.
- It is not possible to open a second popup window with a terminal. **E861**
- The default Pmenu color is only used for the border and padding. To change the color of the terminal itself set the Terminal highlight group before creating the terminal. Setting **'wincolor'** later can work but requires the program in the terminal to redraw everything.
- The default minimal size is 5 lines of 20 characters; Use the "minwidth" and "minheight" parameters to set a different value.
- The terminal size will grow if the program running in the terminal writes text. Set "maxheight" and "maxwidth" to restrict the size.

To run a terminal in a popup window, first create the terminal hidden. Then pass the buffer number to `popup_create()`. Example:

```
hi link Terminal Search
let buf = term_start(['picker', 'Something'], #{hidden: 1, term_finish: 'close'})
let winid = popup_create(buf, #{minwidth: 50, minheight: 20})
```

---

## 2. Functions

[popup-functions](#)

Creating a popup window:

<code>popup_create()</code>	centered in the screen
<code>popup_atcursor()</code>	just above the cursor position, closes when the cursor moves away
<code>popup_beval()</code>	at the position indicated by <code>v:beval_</code> variables, closes when the mouse moves away
<code>popup_notification()</code>	show a notification for three seconds
<code>popup_dialog()</code>	centered with padding and border
<code>popup_menu()</code>	prompt for selecting an item from a list

Manipulating a popup window:

<code>popup_hide()</code>	hide a popup temporarily
<code>popup_show()</code>	show a previously hidden popup
<code>popup_move()</code>	change the position and size of a popup
<code>popup_setoptions()</code>	override options of a popup
<code>popup_settext()</code>	replace the popup buffer contents
<code>popup_setbuf()</code>	set the buffer for the popup window

Closing popup windows:

<code>popup_close()</code>	close one popup
<code>popup_clear()</code>	close all popups

Filter functions:

<code>popup_filter_menu()</code>	select from a list of items
<code>popup_filter_yesno()</code>	blocks until 'y' or 'n' is pressed

Other:

<code>popup_getoptions()</code>	get current options for a popup
<code>popup_getpos()</code>	get actual position and size of a popup
<code>popup_locate()</code>	find popup window at a screen position
<code>popup_list()</code>	get list of all popups

## DETAILS

[popup-function-details](#)

`popup_atcursor({what}, {options})`

[popup\\_atcursor\(\)](#)

Show the `{what}` above the cursor, and close it when the cursor moves. This works like:

```
call popup_create({what}, #{
 \ pos: 'botleft',
 \ line: 'cursor-1',
 \ col: 'cursor',
 \ moved: 'WORD',
 \ })
```

Use `{options}` to change the properties.  
If "pos" is passed as "topleft" then the default for "line" becomes "cursor+1".

Can also be used as a `method` :  
`GetText()->popup_atcursor({})`

Return type: `Number`

`popup_beval({what}, {options})` `popup_beval()`  
Show the `{what}` above the position from '`ballooneval`' and close it when the mouse moves. This works like:  

```
let pos = screenpos(v:beval_winnr, v:beval_lnum, v:beval_col)
call popup_create({what}, #{
 \ pos: 'botleft',
 \ line: pos.row - 1,
 \ col: pos.col,
 \ mousemoved: 'WORD',
 \ })
```

Use `{options}` to change the properties.  
See `popup_beval_example` for an example.

Can also be used as a `method` :  
`GetText()->popup_beval({})`

Return type: `Number`

`popup_clear([force])` `popup_clear()`  
Emergency solution to a misbehaving plugin: close all popup windows for the current tab and global popups. Close callbacks are not invoked. When `force` is not present this will fail if the current window is a popup. When `force` is present and `TRUE` the popup is also closed when it is the current window. If a terminal is running in a popup it is killed.

Return type: `Number`

`popup_close({id} [, {result}])` `popup_close()`  
Close popup `{id}`. The window will be deleted. The associated buffer will be deleted, if the popup created a new buffer.

If the popup has a callback it will be called just before the popup window is deleted. If the optional `{result}` is present it will be passed as the second argument of the callback. Otherwise zero is passed to the callback.

Can also be used as a `method` :  
`GetPopup()->popup_close()`

Return type: `Number`

`popup_create({what}, {options})` `popup_create()`  
Open a popup window showing `{what}`, which is either: `E450`  
- a buffer number  
- a string  
- a list of strings  
- a list of text lines with text properties  
When `{what}` is not a buffer number, a buffer is created with `'buftype'` set to "popup". That buffer will be wiped out once the popup closes.

if `{what}` is a buffer number and loading the buffer runs into an existing swap file, it is silently opened read-only, as if a `SwapExists` autocommand had set `v:swapchoice` to 'o'. This is because we assume the buffer is only used for viewing.

`{options}` is a dictionary with many possible entries. See `popup_create-arguments` for details.

Returns a window-ID, which can be used with other popup functions. Use `'winbufnr()'` to get the number of the buffer in the window:

```
let winid = popup_create('hello', {})
let bufnr = winbufnr(winid)
call setbufline(bufnr, 2, 'second line')
```

In case of failure zero is returned.

Can also be used as a `method` :  
`GetText()->popup_create({})`

Return type: `Number`

`popup_dialog({what}, {options})` `popup_dialog()`  
Just like `popup_create()` but with these default options:  
`call popup_create({what}, #{`  
    `\ pos: 'center',`  
    `\ zindex: 200,`  
    `\ drag: 1,`  
    `\ border: [],`  
    `\ padding: [],`  
    `\ mapping: 0,`  
    `\})`

Use `{options}` to change the properties. E.g. add a `'filter'` option with value 'popup\_filter\_yesno'. Example:  
`call popup_create('do you want to quit (Yes/no)?', #{`  
    `\ filter: 'popup_filter_yesno',`  
    `\ callback: 'QuitCallback',`  
    `\})`

By default the dialog can be dragged, so that text below it can be read if needed.

Can also be used as a [method](#) :  
[GetText\(\)->popup\\_dialog\({}\)](#)

Return type: [Number](#)

[popup\\_filter\\_menu\({id}, {key}\)](#) [popup\\_filter\\_menu\(\)](#)

Filter that can be used for a popup. These keys can be used:

j	<Down> <C-N>	select item below
k	<Up> <C-P>	select item above
	<Space> <Enter>	accept current selection
x	Esc <b>CTRL-C</b>	cancel the menu

Other keys are ignored.  
Always returns [v:true](#) .

A match is set on that line to highlight it, see  
[popup\\_menu\(\)](#) .

When the current selection is accepted the "callback" of the popup menu is invoked with the index of the selected line as the second argument. The first entry has index one. Cancelling the menu invokes the callback with -1.

To add shortcut keys, see the example here:  
[popup\\_menu-shortcut-example](#)

Return type: [Number](#)

[popup\\_filter\\_ynno\({id}, {key}\)](#) [popup\\_filter\\_ynno\(\)](#)

Filter that can be used for a popup. It handles only the keys 'y', 'Y' and 'n' or 'N'. Invokes the "callback" of the popup menu with the 1 for 'y' or 'Y' and zero for 'n' or 'N' as the second argument. Pressing Esc and 'x' works like pressing 'n'. **CTRL-C** invokes the callback with -1. Other keys are ignored.

See the example here: [popup\\_dialog-example](#)

Return type: [Number](#)

[popup\\_findecho\(\)](#) [popup\\_findecho\(\)](#)

Get the [window-ID](#) for the popup that shows messages for the `:echowindow`` command. Return zero if there is none. Mainly useful to hide the popup.

Return type: [Number](#)

[popup\\_findinfo\(\)](#) [popup\\_findinfo\(\)](#)

Get the [window-ID](#) for the popup info window, as it used by the popup menu. See [complete-popup](#) . The info popup is hidden when not used, it can be deleted with [popup\\_clear\(\)](#)

and `popup_close()` . Use `popup_show()` to reposition it to the item in the popup menu.  
Returns zero if there is none.

Return type: `Number`

`popup_findpreview()` `popup_findpreview()`  
Get the `window-ID` for the popup preview window.  
Return zero if there is none.

Return type: `Number`

`popup_getoptions({id})` `popup_getoptions()`  
Return the `{options}` for popup `{id}` in a Dict.  
A zero value means the option was not set. For "zindex" the default value is returned, not zero.

The "moved" entry is a list with line number, minimum and maximum column, `[0, 0, 0]` when not set.

The "mousemoved" entry is a list with screen row, minimum and maximum screen column, `[0, 0, 0]` when not set.

"firstline" is the property set on the popup, unlike the "firstline" obtained with `popup_getpos()` which is the actual buffer line at the top of the popup window.

"border" and "padding" are not included when all values are zero. When all values are one then an empty list is included.

"borderhighlight" is not included when all values are empty. "scrollbarhighlight" and "thumbhighlight" are only included when set.

"tabpage" will be -1 for a global popup, zero for a popup on the current tabpage and a positive number for a popup on another tabpage.

"textprop", "textpropid" and "textpropwin" are only present when "textprop" was set.

If popup window `{id}` is not found an empty Dict is returned.

Can also be used as a `method` :  
`GetPopup()->popup_getoptions()`

Return type: `dict<any>`

`popup_getpos({id})` `popup_getpos()`  
Return the position and size of popup `{id}`. Returns a Dict with these entries:

col	screen column of the popup, one-based
line	screen line of the popup, one-based
width	width of the whole popup in screen cells
height	height of the whole popup in screen cells
core_col	screen column of the text box
core_line	screen line of the text box
core_width	width of the text box in screen cells
core_height	height of the text box in screen cells
firstline	line of the buffer at top (1 unless scrolled) (not the value of the "firstline" property)
lastline	line of the buffer at the bottom (updated when the popup is redrawn)
scrollbar	non-zero if a scrollbar is displayed
visible	one if the popup is displayed, zero if hidden

Note that these are the actual screen positions. They differ from the values in `popup_getoptions()` for the sizing and positioning mechanism applied.

The "core\_" values exclude the padding and border.

If popup window `{id}` is not found an empty Dict is returned.

Can also be used as a `method` :  
`GetPopup()->popup_getpos()`

Return type: dict<number> or dict<any>

`popup_hide({id})` `popup_hide()`  
 If `{id}` is a displayed popup, hide it now. If the popup has a filter it will not be invoked for so long as the popup is hidden.  
 If window `{id}` does not exist nothing happens. If window `{id}` exists but is not a popup window an error is given. **E993**  
 If popup window `{id}` contains a terminal an error is given.

Can also be used as a `method` :  
`GetPopup()->popup_hide()`

Return type: `Number`

`popup_list()` `popup_list()`  
 Return a List with the `window-ID` of all existing popups.

Return type: list<number> or list<any>

`popup_locate({row}, {col})` `popup_locate()`  
 Return the `window-ID` of the popup at screen position `{row}` and `{col}`. If there are multiple popups the one with the highest zindex is returned. If there are no popups at this position then zero is returned.

Return type: [Number](#)

`popup_menu({what}, {options})` [popup\\_menu\(\)](#)  
Show the `{what}` near the cursor, handle selecting one of the items with cursorkeys, and close it an item is selected with Space or Enter. `{what}` should have multiple lines to make this useful. This works like:

```
call popup_create({what}, #{
 \ pos: 'center',
 \ zindex: 200,
 \ drag: 1,
 \ wrap: 0,
 \ border: [],
 \ cursorline: 1,
 \ padding: [0,1,0,1],
 \ filter: 'popup_filter_menu',
 \ mapping: 0,
 \ })
```

The current line is highlighted with a match using `hl-PopupSelected` which is linked to "PmenuSel" by default.

Use `{options}` to change the properties. Should at least set "callback" to a function that handles the selected item.

Example:

```
func ColorSelected(id, result)
 " use a:result
endfunc
call popup_menu(['red', 'green', 'blue'], #{
 \ callback: 'ColorSelected',
 \ })
```

Can also be used as a [method](#) :

```
GetChoices()->popup_menu({})
```

Return type: [Number](#)

`popup_move({id}, {options})` [popup\\_move\(\)](#)  
Move popup `{id}` to the position specified with `{options}`. `{options}` may contain the items from `popup_create()` that specify the popup position:

```
line
col
pos
maxheight
minheight
maxwidth
minwidth
fixed
```

For `{id}` see ``popup_hide()``.

For other options see `popup_setoptions()` .

Can also be used as a [method](#) :

`GetPopup()->popup_move(options)`

Return type: `Number`

`popup_notification({what}, {options})` `popup_notification()`

Show the `{what}` for 3 seconds at the top of the Vim window.

This works like:

```
call popup_create({what}, #{
 \ line: 1,
 \ col: 10,
 \ minwidth: 20,
 \ time: 3000,
 \ tabpage: -1,
 \ zindex: 300,
 \ drag: 1,
 \ highlight: 'WarningMsg',
 \ border: [],
 \ close: 'click',
 \ padding: [0,1,0,1],
 \ })
```

The `hl-PopupNotification` highlight group is used instead of `WarningMsg` if it is defined.

Without the `+timers` feature the popup will not disappear automatically, the user has to click in it.

The position will be adjusted to avoid overlap with other notifications.

Use `{options}` to change the properties.

Can also be used as a `method` :

```
GetText()->popup_notification({})
```

Return type: `Number`

`popup_setbuf({id}, {buf})` `popup_setbuf()`

Set buffer `{buf}` to be displayed in popup win `{id}`. For the use of `{buf}`, see `bufname()` function.

May change window size or position to adjust for the size of the buffer text.

Can also be used as a `method` :

```
GetPopup()->popup_setbuf(bufnr('foobar'))
```

Return type: `vim9-boolean`

`popup_setoptions({id}, {options})` `popup_setoptions()`

Override options in popup `{id}` with entries in `{options}`.

These options can be set:

```
border
borderchars
```

borderhighlight  
callback  
close  
cursorline  
drag  
filter  
firstline  
flip  
highlight  
mapping  
mask  
moved  
padding  
resize  
scrollbar  
scrollbarhighlight  
thumbhighlight  
time  
title  
wrap  
zindex

The options from `popup_move()` can also be used. Generally, setting an option to zero or an empty string resets it to the default value, but there are exceptions. For "hidden" use `popup_hide()` and `popup_show()`. "tabpage" cannot be changed.

Can also be used as a `method` :  
`GetPopup()->popup_setoptions(options)`

Return type: `Number`

`popup_settext({id}, {text})` `popup_settext()`  
Set the text of the buffer in popup win {id}. {text} is a string or a list of strings to be displayed in the popup. Does not change the window size or position, other than caused by the different text.

Can also be used as a `method` :  
`GetPopup()->popup_settext('hello')`

Return type: `Number`

`popup_show({id})` `popup_show()`  
If {id} is a hidden popup, show it now. For {id} see `popup_hide()`. If {id} is the info popup it will be positioned next to the current popup menu item.

Return type: `Number`

---

### 3. Usage

popup-usage

#### POPUP\_CREATE() ARGUMENTS

popup\_create-arguments

The first argument of `popup_create()` (and the second argument to `popup_settext()`) specifies the text to be displayed, and optionally text properties. It is in one of four forms: [E1284](#)

- a buffer number
- a string
- a list of strings
- a list of dictionaries, where each dictionary has these entries:

text	String with the text to display.
props	A list of text properties. Optional. Each entry is a dictionary, like the third argument of <code>prop_add()</code> , but specifying the column in the dictionary with a "col" entry, see below: <a href="#">popup-props</a> .

If you want to create a new buffer yourself use `bufadd()` and pass the buffer number to `popup_create()`.

The second argument of `popup_create()` is a dictionary with options:

line	Screen line where to position the popup. Can use a number or "cursor", "cursor+1" or "cursor-1" to use the line of the cursor and add or subtract a number of lines. If omitted or zero the popup is vertically centered. The first line is 1. When using "textprop" the number is relative to the text property and can be negative.
col	Screen column where to position the popup. Can use a number or "cursor" to use the column of the cursor, "cursor+9" or "cursor-9" to add or subtract a number of columns. If omitted or zero the popup is horizontally centered. The first column is 1. When using "textprop" the number is relative to the text property and can be negative.
pos	"topleft", "topright", "botleft" or "botright": defines what corner of the popup "line" and "col" are used for. When not set "topleft" is used. Alternatively "center" can be used to position the popup in the center of the Vim window, in which case "line" and "col" are ignored.
posinvert	When FALSE the value of "pos" is always used. When TRUE (the default) and the popup does not fit vertically and there is more space on the other side then the popup is placed on the other side of the position indicated by "line".
textprop	When present the popup is positioned next to a text property with this name and will move when the text property moves. Use an empty string to remove. See <a href="#">popup-textprop-pos</a> .
textpropwin	What window to search for the text property. When omitted or invalid the current window is used. Used

	when "textprop" is present.
textpropid	Used to identify the text property when "textprop" is present. Use zero to reset.
fixed	When FALSE (the default), and: <ul style="list-style-type: none"> <li>- "pos" is "botleft" or "topleft", and</li> <li>- the popup would be truncated at the right edge of the screen, then</li> </ul> the popup is moved to the left so as to fit the contents on the screen. Set to TRUE to disable this.
flip	When TRUE (the default) and the position is relative to the cursor, flip to below or above the cursor to avoid overlap with the <code>popupmenu-completion</code> or another popup with a higher "zindex". When there is no space above/below the cursor then show the popup to the side of the popup or popup menu. {not implemented yet}
maxheight	Maximum height of the contents, excluding border and padding.
minheight	Minimum height of the contents, excluding border and padding.
maxwidth	Maximum width of the contents, excluding border, padding and scrollbar.
minwidth	Minimum width of the contents, excluding border, padding and scrollbar.
firstline	First buffer line to display. When larger than one it looks like the text scrolled up. When out of range the last buffer line will at the top of the window. Set to zero to leave the position as set by commands. Also see "scrollbar".
hidden	When TRUE the popup exists but is not displayed; use <code>`popup_show()`</code> to unhide it.
tabpage	When -1: display the popup on all tab pages. When 0 (the default): display the popup on the current tab page. Otherwise the number of the tab page the popup is displayed on; when invalid the popup is not created and an error is given. E997
title	Text to be displayed above the first item in the popup, on top of any border. If there is no top border one line of padding is added to put the title on. You might want to add one or more spaces at the start and end as padding.
wrap	TRUE to make the lines wrap (default TRUE).
drag	TRUE to allow the popup to be dragged with the mouse by grabbing at the border. Has no effect if the popup does not have a border. As soon as dragging starts and "pos" is "center" it is changed to "topleft".
dragall	TRUE to allow the popup to be dragged from every position. Makes it very difficult to select text in the popup.
resize	TRUE to allow the popup to be resized with the mouse by grabbing at the bottom right corner. Has no effect if the popup does not have a border.

close	When "button" an X is displayed in the top-right, on top of any border, padding or text. When clicked on the X the popup will close. Any callback is invoked with the value -2. When "click" any mouse click in the popup will close it. When "none" (the default) mouse clicks do not close the popup window.
highlight	Highlight group name to use for the text, stored in the <b>'wincolor'</b> option.
padding	List with numbers, defining the padding above/right/below/left of the popup (similar to CSS). An empty list uses a padding of 1 all around. The padding goes around the text, inside any border. Padding uses the <b>'wincolor'</b> highlight. Example: [1, 2, 1, 3] has 1 line of padding above, 2 columns on the right, 1 line below and 3 columns on the left.
border	List with numbers, defining the border thickness above/right/below/left of the popup (similar to CSS). Only values of zero and non-zero are currently recognized. An empty list uses a border all around.
borderhighlight	List of highlight group names to use for the border. When one entry it is used for all borders, otherwise the highlight for the top/right/bottom/left border. Example: ['TopColor', 'RightColor', 'BottomColor', 'LeftColor']
borderchars	List with characters, defining the character to use for the top/right/bottom/left border. Optionally followed by the character to use for the topleft/topright/botright/botleft corner. Example: ['- ', ' ', '- ', ' ', '┌', '┐', '└', '┘'] When the list has one character it is used for all. When the list has two characters the first is used for the border lines, the second for the corners. By default a double line is used all around when <b>'encoding'</b> is "utf-8" and <b>'ambiwidth'</b> is "single", otherwise ASCII characters are used.
scrollbar	1 or true: show a scrollbar when the text doesn't fit. zero: do not show a scrollbar. Default is non-zero. Also see <a href="#">popup-scrollbar</a> .
scrollbarhighlight	Highlight group name for the scrollbar. The background color is what matters. When not given then PmenuSbar is used.
thumbhighlight	Highlight group name for the scrollbar thumb. The background color is what matters. When not given then PmenuThumb is used.
zindex	Priority for the popup, default 50. Minimum value is 1, maximum value is 32000.
mask	A list of lists with coordinates, defining parts of the popup that are transparent. See <a href="#">popup-mask</a> .
time	Time in milliseconds after which the popup will close. When omitted <a href="#">popup_close()</a> must be used.
moved	Specifies to close the popup if the cursor moved:

- "any": if the cursor moved at all
- "word": if the cursor moved outside `<cword>`
- "WORD": if the cursor moved outside `<cWORD>`
- "expr": if the cursor moved outside `<cexpr>`
- `[{start}, {end}]`: if the cursor moved before column `{start}` or after `{end}`
- `[{lnum}, {start}, {end}]`: if the cursor moved away from line `{lnum}`, before column `{start}` or after `{end}`
- `[0, 0, 0]` do not close the popup when the cursor moves

The popup also closes if the cursor moves to another line or to another window.

mousemoved	Like "moved" but referring to the mouse pointer position
cursorline	TRUE: Highlight the cursor line. Also scrolls the text to show this line (only works properly when <code>'wrap'</code> is off). zero: Do not highlight the cursor line. Default is zero, except for <code>popup_menu()</code> .
filter	A callback that can filter typed characters, see <code>popup-filter</code> .
mapping	Allow for key mapping. When FALSE and the popup is visible and has a filter callback key mapping is disabled. Default value is TRUE.
filtermode	In which modes the filter is used (same flags as with <code>hasmapto()</code> plus "a"): <ul style="list-style-type: none"> <li>n Normal mode</li> <li>v Visual and Select mode</li> <li>x Visual mode</li> <li>s Select mode</li> <li>o Operator-pending mode</li> <li>i Insert mode</li> <li>l Language-Argument ("r", "f", "t", etc.)</li> <li>c Command-line mode</li> <li>a all modes</li> </ul> The default value is "a".
callback	A callback that is called when the popup closes, e.g. when using <code>popup_filter_menu()</code> , see <code>popup-callback</code> .

Depending on the "zindex" the popup goes under or above other popups. The completion menu (`popup-menu`) has zindex 100. For messages that occur for a short time the suggestion is to use zindex 1000.

By default text wraps, which causes a line in `{lines}` to occupy more than one screen line. When "wrap" is FALSE then the text outside of the popup or outside of the Vim window will not be displayed, thus truncated.

## POPUP TEXT PROPERTIES

`popup-props`

These are similar to the third argument of `prop_add()` except:

- "lnum" is always the current line in the list
- "bufnr" is always the buffer of the popup

- "col" is in the Dict instead of a separate argument

So we get:

col	starting column, counted in bytes, use one for the first column.
length	length of text in bytes; can be zero
end_lnum	line number for the end of the text
end_col	column just after the text; not used when "length" is present; when {col} and "end_col" are equal, this is a zero-width text property
id	user defined ID for the property; when omitted zero is used
type	name of the text property type, as added with <code>prop_type_add()</code>

### POSITION POPUP WITH TEXTPROP

popup-textprop-pos

Positioning a popup next to a text property causes the popup to move when text is inserted or deleted. The popup functions like a tooltip.

These steps are needed to make this work:

- Define a text property type, it defines the name.

```
call prop_type_add('popupMarker', {})
```

- Place a text property at the desired text:

```
let lnum = {line of the text}
let col = {start column of the text}
let len = {length of the text}
let propId = {arbitrary but unique number}
call prop_add(lnum, col, #{
 \ length: len,
 \ type: 'popupMarker',
 \ id: propId,
 \ })
```

- Create a popup:

```
let winid = popup_create('the text', #{
 \ pos: 'botleft',
 \ textprop: 'popupMarker',
 \ textpropid: propId,
 \ border: [],
 \ padding: [0,1,0,1],
 \ close: 'click',
 \ })
```

By default the popup is positioned at the corner of the text, opposite of the "pos" specified for the popup. Thus when the popup uses "botleft", the bottom-left corner of the popup is positioned next to the top-right corner of the text property:

```
+-----+
| the text |
+-----+
```

just some PROPERTY as an example

Here the text property is on "PROPERTY". Move the popup to the left by passing a negative "col" value to popup\_create(). With "col: -5" you get:

```
+-----+
| the text |
+-----+
```

just some PROPERTY as an example

If the text property moves out of view then the popup will be hidden.  
If the window for which the popup was defined is closed, the popup is closed.

If the popup cannot fit in the desired position, it may show at a nearby position.

Some hints:

- To avoid collision with other plugins the text property type name has to be unique. You can also use the "bufnr" item to make it local to a buffer.
- You can leave out the text property ID if there is only ever one text property visible.
- The popup may be in the way of what the user is doing, making it close with a click, as in the example above, helps for that.
- If the text property is removed the popup is closed. Use something like this:

```
call prop_remove({type: 'popupMarker', id: propId})
```

## POPUP FILTER

## popup-filter

A callback that gets any typed keys while a popup is displayed. The filter is not invoked when the popup is hidden.

The filter can return TRUE to indicate the key has been handled and is to be discarded, or FALSE to let Vim handle the key as usual in the current state. In case it returns FALSE and there is another popup window visible, that filter is also called. The filter of the popup window with the highest zindex is called first.

The filter function is called with two arguments: the ID of the popup and the key as a string, e.g.:

```
func MyFilter(winid, key)
 if a:key == "\<F2>"
 " do something
 return 1
 endif
 if a:key == 'x'
 call popup_close(a:winid)
 return 1
 endif
 return 0
endfunc
```

## popup-filter-mode

The "filtermode" property can be used to specify in what mode the filter is invoked. The default is "a": all modes. When using "nvi" Command-line mode

is not included, so that any command typed on the command line is not filtered. However, to get to Command-line mode the filter must not consume ":". Just like it must not consume "v" to allow for entering Visual mode.

#### popup-mapping

Normally the key is what results after any mapping, since the keys pass on as normal input if the filter does not use it. If the filter consumes all the keys, set the "mapping" property to zero so that mappings do not get in the way. This is default for `popup_menu()` and `popup_dialog()` .

Some recommended key actions:

x	close the popup (see <a href="#">note</a> below)
cursor keys	select another entry
Tab	accept current suggestion

When **CTRL-C** is pressed the popup is closed, the filter will not be invoked.

A mouse click arrives as `<LeftMouse>`. The coordinates can be obtained with `getmousepos()` .

Vim provides standard filters `popup_filter_menu()` and `popup_filter_yesno()` .

Keys coming from a `:normal` command do not pass through the filter. This can be used to move the cursor in a popup where the "cursorline" option is set:

```
call win_execute(winid, 'normal! 10Gzz')
```

Keys coming from `feedkeys()` are passed through the filter.

**Note** that "x" is the normal way to close a popup. You may want to use Esc, but since many keys start with an Esc character, there may be a delay before Vim recognizes the Esc key. If you do use Esc, it is recommended to set the `'timeoutlen'` option to 100 and set `'timeout'` and/or `'ttimeout'`.

#### popup-filter-errors

If the filter function can't be called, e.g. because the name is wrong, then the popup is closed. If the filter causes an error then it is assumed to return zero. If this happens three times in a row the popup is closed. If the popup gives errors fewer than 10% of the calls then it won't be closed.

## POPUP CALLBACK

#### popup-callback

A callback that is invoked when the popup closes.

The callback is invoked with two arguments: the ID of the popup window and the result, which could be an index in the popup lines, or whatever was passed as the second argument of `popup_close()`.

If the popup is force-closed, e.g. because the cursor moved or **CTRL-C** was pressed, the number -1 is passed to the callback.

Example:

```
func SelectedColor(id, result)
 echo 'choice made: ' .. a:result
```

endfunc

## POPUP SCROLLBAR

popup-scrollbar

If the text does not fit in the popup a scrollbar is displayed on the right of the window. This can be disabled by setting the "scrollbar" option to zero. When the scrollbar is displayed mouse scroll events, while the mouse pointer is on the popup, will cause the text to scroll up or down as you would expect. A click in the upper half of the scrollbar will scroll the text down one line. A click in the lower half will scroll the text up one line. However, this is limited so that the popup does not get smaller.

## POPUP MASK

popup-mask

To minimize the text that the popup covers, parts of it can be made transparent. This is defined by a "mask" which is a list of lists, where each list has four numbers:

```
col start column, positive for counting from the left, 1 for
 leftmost, negative for counting from the right, -1 for
 rightmost
endcol last column, like "col"
line start line, positive for counting from the top, 1 for top,
 negative for counting from the bottom, -1 for bottom
endline end line, like "line"
```

For example, to make the last 10 columns of the last line transparent:

```
[[-10, -1, -1, -1]]
```

To make the four corners transparent:

```
[[1, 1, 1, 1], [-1, -1, 1, 1], [1, 1, -1, -1], [-1, -1, -1, -1]]
```

---

## 4. Examples

popup-examples

These examples use `Vim9` script.

popup\_dialog-example

Prompt the user to press y/Y or n/N:

```
popup_dialog('Continue? y/n', {
 filter: 'popup_filter_yesno',
 callback: (id, result) => {
 if result == 1
 echomsg "'y' or 'Y' was pressed"
 else
 echomsg "'y' or 'Y' was NOT pressed"
 endif
 },
 padding: [2, 4, 2, 4],
})
```

popup\_menu-shortcut-example

Extend `popup_filter_menu()` with shortcut keys:

```
popup_menu(['Save', 'Cancel', 'Discard'], {
 callback: (_, result) => {
 echo 'dialog result is' result
 },
 filter: (id, key) => {
 # Handle shortcuts
 if key == 'S' || key == 's'
 popup_close(id, 1)
 elseif key == 'C' || key == 'c'
 popup_close(id, 2)
 elseif key == 'D' || key == 'd'
 popup_close(id, 3)
 else
 # No shortcut, pass to generic filter
 return popup_filter_menu(id, key)
 endif
 return true
 },
})
```

Example for using a popup window for `popup_beval_example` **'ballooneval'**:

```
set ballooneval balloonevalterm
set balloonexpr=BalloonExpr()
var winid: number
var last_text: string

def BalloonExpr(): string
 # here you would use "v:beval_text" to lookup something interesting
 var text = v:beval_text
 if winid > 0 && popup_getpos(winid) != null_dict
 # previous popup window still shows
 if text == last_text
 # still the same text, keep the existing popup
 return null_string
 endif
 popup_close(winid)
 endif

 winid = popup_beval(text, {})
 last_text = text
 return null_string
enddef
```

If the text has to be obtained asynchronously return an empty string from the expression function and call `popup_beval()` once the text is available. In this example simulated with a timer callback:

```
set ballooneval balloonevalterm
set balloonexpr=BalloonExpr()
var winid: number
```

```

var last_text: string

def BalloonExpr(): string
 var text = v:beval_text
 if winid > 0 && popup_getpos(winid) != null_dict
 # previous popup window still shows
 if text == last_text
 # still the same text, keep the existing popup
 return null_string
 endif
 popup_close(winid)
 endif

 # Simulate an asynchronous lookup that takes half a second for the
 # text to display.
 last_text = text
 timer_start(500, 'ShowPopup')
 return null_string
enddef

def ShowPopup(timerid: number)
 winid = popup_beval('Result: ' .. last_text, {})
enddef

```

Vim9 script commands and expressions.

Vim9 vim9

Most expression help is in [eval.txt](#) . This file is about the new syntax and features in Vim9 script.

## 1. What is Vim9 script?

Vim9-script

Vim script has been growing over time, while preserving backwards compatibility. That means bad choices from the past often can't be changed and compatibility with Vi restricts possible solutions. Execution is quite slow, each line is parsed every time it is executed.

The main goal of Vim9 script is to drastically improve performance. This is accomplished by compiling commands into instructions that can be efficiently executed. An increase in execution speed of 10 to 100 times can be expected.

A secondary goal is to avoid Vim-specific constructs and get closer to commonly used programming languages, such as JavaScript, TypeScript and Java.

The performance improvements can only be achieved by not being 100% backwards compatible. For example, making function arguments available in the "a:" dictionary adds quite a lot of overhead. In a Vim9 function this dictionary is not available. Other differences are more subtle, such as how errors are handled.

The Vim9 script syntax and semantics are used in:

- a function defined with the `:def` command
- a script file where the first command is `vim9script`
- an autocommand defined in the context of the above
- a command prefixed with the `vim9cmd` command modifier

When using `:function` in a Vim9 script file the legacy syntax is used, with the highest `scriptversion` . However, this can be confusing and is therefore discouraged.

Vim9 script and legacy Vim script can be mixed. There is no requirement to rewrite old scripts, they keep working as before. You may want to use a few ``:def`` functions for code that needs to be fast.

```
:vim9[cmd] {cmd} :vim9 :vim9cmd E1164
 Evaluate and execute {cmd} using Vim9 script syntax and semantics. Useful when typing a command and in a legacy script or function.
```

```
:leg[acy] {cmd} :leg :legacy E1189 E1234
 Evaluate and execute {cmd} using legacy script syntax and semantics. Only useful in a Vim9 script or a :def function.
 Note that {cmd} cannot use local variables, since it is parsed with legacy expression syntax.
```

See some examples of Vim9 script at [52.6](#) .

---

## 2. Differences from legacy Vim script

[vim9-differences](#)

### Overview

[E1146](#)

Brief summary of the differences you will most often encounter when using Vim9 script and ``:def`` functions; details are below:

- Comments start with #, not "

```
echo "hello" # comment
```
- Using a backslash for line continuation is hardly ever needed:

```
echo "hello "
 .. yourName
 .. ", how are you?"
```
- White space is required in many places to improve readability.
- Assign values without ``:let`` [E1126](#) , declare variables with ``:var``:

```
var count = 0
count += 3
```
- Constants can be declared with ``:final`` and ``:const``:

```
final matches = [] # add to the list later
const names = ['Betty', 'Peter'] # cannot be changed
```
- ``:final`` cannot be used as an abbreviation of ``:finally``.
- Variables and functions are script-local by default.
- Functions are declared with argument types and return type:

```
def CallMe(count: number, message: string): bool
```
- Call functions without ``:call``:

```
writefile(['done'], 'file.txt')
```
- You cannot use old Ex commands:

```
`:Print`
`:append`
`:change`
`:d` directly followed by 'd' or 'p'.
`:insert`
`:k`
`:mode`
`:open`
`:s` with only flags
`:t`
```

- Some commands, especially those used for flow control, cannot be shortened. E.g., ``:throw`` cannot be written as ``:th``. [vim9-no-shorten](#)
- You cannot use curly-braces names.
- A range before a command must be prefixed with a colon:
  - `:%s/this/that`
- Executing a register with "@r" does not work, you can prepend a colon or use ``:exe``:
  - `:exe @a`
- Unless mentioned specifically, the highest `scriptversion` is used.
- When defining an expression mapping, the expression will be evaluated in the context of the script where it was defined.
- When indexing a string the index is counted in characters, not bytes:
  - [vim9-string-index](#)
- Some possibly unexpected differences: [vim9-gotchas](#) .

### Comments starting with #

In legacy Vim script comments start with double quote. In Vim9 script comments start with #.

```
declarations
var count = 0 # number of occurrences
```

The reason is that a double quote can also be the start of a string. In many places, especially halfway through an expression with a line break, it's hard to tell what the meaning is, since both a string and a comment can be followed by arbitrary text. To avoid confusion only # comments are recognized. This is the same as in shell scripts and Python programs.

In Vi # is a command to list text with numbers. In Vim9 script you can use ``:number`` for that.

```
:101 number
```

To improve readability there must be a space between a command and the # that starts a comment:

```
var name = value # comment
var name = value# error!
```

[E1170](#)

Do not start a comment with #{, it looks like the legacy dictionary literal and produces an error where this might be confusing. #{{ or #{{{ are OK, these can be used to start a fold.

When starting to read a script file Vim doesn't know it is `Vim9` script until the ``vim9script`` command is found. Until that point you would need to use legacy comments:

```
" legacy comment
vim9script
Vim9 comment
```

That looks ugly, better put ``vim9script`` in the very first line:

```
vim9script
Vim9 comment
```

In legacy Vim script # is also used for the alternate file name. In Vim9 script you need to use %% instead. Instead of ## use %%% (stands for all arguments).

## Vim9 functions

E1099

A function defined with `:def` is compiled. Execution is many times faster, often 10 to 100 times.

Many errors are already found when compiling, before the function is executed. The syntax is strict, to enforce code that is easy to read and understand.

Compilation is done when any of these is encountered:

- the first time the function is called
- when the `:defcompile` command is encountered in the script after the function was defined
- `:disassemble` is used for the function.
- a function that is compiled calls the function or uses it as a function reference (so that the argument and return types can be checked)

E1091 E1191

If compilation fails it is not tried again on the next call, instead this error is given: "E1091: Function is not compiled: {name}".

Compilation will fail when encountering a user command that has not been created yet. In this case you can call `execute()` to invoke it at runtime.

```
def MyFunc()
 execute('DefinedLater')
enddef
```

`:def` has no options like `:function` does: "range", "abort", "dict" or "closure". A `:def` function always aborts on an error (unless `:silent!` was used for the command or the error was caught a `:try` block), does not get a range passed, cannot be a "dict" function, and can always be a closure.

vim9-no-dict-function E1182

You can use a Vim9 Class ( `Vim9-class` ) instead of a "dict function".

You can also pass the dictionary explicitly:

```
def DictFunc(self: dict<any>, arg: string)
 echo self[arg]
enddef
var ad = {item: 'value', func: DictFunc}
ad.func(ad, 'item')
```

You can call a legacy dict function though:

```
func Legacy() dict
 echo self.value
endfunc
def CallLegacy()
 var d = {func: Legacy, value: 'text'}
 d.func()
enddef
```

E1096 E1174 E1175

The argument types and return type need to be specified. The "any" type can be used, type checking will then be done at runtime, like with legacy functions.

E1106

Arguments are accessed by name, without "a:", just like any other language. There is no "a:" dictionary or "a:000" list.

vim9-variable-arguments E1055 E1160 E1180

Variable arguments are defined as the last argument, with a name and have a list type, similar to TypeScript. For example, a list of numbers:

```
def MyFunc(...itemlist: list<number>)
 for item in itemlist
 ...
```

When a function argument is optional (it has a default value) passing `v:none` as the argument results in using the default value. This is useful when you want to specify a value for an argument that comes after an argument that should use its default value. Example:

```
def MyFunc(one = 'one', last = 'last')
 ...
enddef
MyFunc(v:none, 'LAST') # first argument uses default value 'one'
```

vim9-ignored-argument E1181

The argument "\_" (an underscore) can be used to ignore the argument. This is most useful in callbacks where you don't need it, but do need to give an argument to match the call. E.g. when using map() two arguments are passed, the key and the value, to ignore the key:

```
map(numberList, (_, v) => v * 2)
```

There is no error for using the "\_" argument multiple times. No type needs to be given.

## Functions and variables are script-local by default

vim9-scopes

When using `:function` or `:def` to specify a new function at the script level in a Vim9 script, the function is local to the script. Like prefixing "s:" in legacy script. To define a global function or variable the "g:" prefix must be used. For functions in a script that is to be imported and in an autoload script "export" needs to be used for those to be used elsewhere.

```
def ThisFunction() # script-local
def g:ThatFunction() # global
export def Function() # for import and import autoload
```

E1058 E1075

When using `:function` or `:def` to specify a nested function inside a `:def` function and no namespace was given, this nested function is local to the code block it is defined in. It cannot be used in `function()` with a string argument, pass the function reference itself:

```
def Outer()
 def Inner()
 echo 'inner'
 enddef
 var Fok = function(Inner) # OK
 var Fbad = function('Inner') # does not work
```

Detail: this is because "Inner" will actually become a function reference to a function with a generated name.

It is not possible to define a script-local function in a function. You can define a local function and assign it to a script-local Funcref (it must have been declared at the script level). It is possible to define a global function by using the "g:" prefix.

When referring to a function and no "s:" or "g:" prefix is used, Vim will search for the function:

- in the function scope, in block scopes
- in the script scope

Imported functions are found with the prefix from the `:import` command.

Since a script-local function reference can be used without "s:" the name must start with an upper case letter even when using the "s:" prefix. In legacy script "s:funcref" could be used, because it could not be referred to with "funcref". In Vim9 script it can, therefore "s:Funcref" must be used to avoid that the name interferes with builtin functions.

`vim9-s-namespace` E1268

The use of the "s:" prefix is not supported at the Vim9 script level. All functions and variables without a prefix are script-local.

In `:def` functions the use of "s:" depends on the script: Script-local variables and functions in a legacy script do use "s:", while in a Vim9 script they do not use "s:". This matches what you see in the rest of the file.

In legacy functions the use of "s:" for script items is required, as before. No matter if the script is Vim9 or legacy.

In all cases the function must be defined before used. That is when it is called, when `:defcompile` causes it to be compiled, or when code that calls it is being compiled (to figure out the return type).

The result is that functions and variables without a namespace can usually be found in the script, either defined there or imported. Global functions and variables could be defined anywhere (good luck finding out where! You can often see where it was last set using `:verbose`).

E1102

Global functions can still be defined and deleted at nearly any time. In Vim9 script script-local functions are defined once when the script is sourced and cannot be deleted or replaced by itself (it can be by reloading the script).

When compiling a function and a function call is encountered for a function that is not (yet) defined, the `FuncUndefined` autocommand is not triggered. You can use an autoloading function if needed, or call a legacy function and have `FuncUndefined` triggered there.

Reloading a Vim9 script clears functions and variables by default

`vim9-reload` E1149 E1150

When loading a legacy Vim script a second time nothing is removed, the commands will replace existing variables and functions, create new ones, and leave removed things hanging around.

When loading a Vim9 script a second time all existing script-local functions and variables are deleted, thus you start with a clean slate. This is useful if you are developing a plugin and want to try a new version. If you renamed something you don't have to worry about the old name still hanging around.

If you do want to keep items, use:

```
vim9script noclear
```

You want to use this in scripts that use a `finish` command to bail out at some point when loaded again. E.g. when a buffer local option is set to a function, the function does not need to be defined more than once:

```
vim9script noclear
setlocal completefunc=SomeFunc
if exists('*SomeFunc')
 finish
endif
def SomeFunc()
....
```

Variable declarations with `:var`, `:final` and `:const`

```
vim9-declaration :var E1079
E1017 E1020 E1054 E1087 E1124
```

Local variables need to be declared with `:var`. Local constants need to be declared with `:final` or `:const`. We refer to both as "variables" in this section.

Variables can be local to a script, function or code block:

```
vim9script
var script_var = 123
def SomeFunc()
 var func_var = script_var
 if cond
 var block_var = func_var
 ...
```

The variables are only visible in the block where they are defined and nested blocks. Once the block ends the variable is no longer accessible:

```
if cond
 var inner = 5
else
 var inner = 0
endif
echo inner # Error!
```

The declaration must be done earlier:

```
var inner: number
if cond
 inner = 5
else
 inner = 0
endif
echo inner
```

Although this is shorter and faster for simple values:

```
var inner = 0
if cond
 inner = 5
endif
echo inner
```

E1025 E1128

To intentionally hide a variable from code that follows, a block can be used:

```
{
 var temp = 'temp'
 ...
}
echo temp # Error!
```

This is especially useful in a user command:

```
command -range Rename {
 var save = @a
 @a = 'some expression'
 echo 'do something with ' .. @a
 @a = save
}
```

And with autocommands:

```
au BufWritePre *.go {
 var save = winsaveview()
 silent! exe ':%! some formatting command'
 winrestview(save)
}
```

Although using a `:def` function probably works better.

E1022 E1103 E1130 E1131 E1133  
E1134

Declaring a variable with a type but without an initializer will initialize to false (for bool), empty (for string, list, dict, etc.) or zero (for number, any, etc.). This matters especially when using the "any" type, the value will default to the number zero. For example, when declaring a list, items can be added:

```
var myList: list<number>
myList->add(7)
```

Initializing a variable to a null value, e.g. ``null_list``, differs from not initializing the variable. This throws an error:

```
var myList = null_list
myList->add(7) # E1130: Cannot add to null list
```

E1016 E1052 E1066

In Vim9 script ``:let`` cannot be used. An existing variable is assigned to without any command. The same for global, window, tab, buffer and Vim variables, because they are not really declared. Those can also be deleted with ``:unlet``.

E1065

You cannot use ``:va`` to declare a variable, it must be written with the full

name ``:var``. Just to make sure it is easy to read.

E1178

``:lockvar`` does not work on local variables. Use ``:const`` and ``:final`` instead.

The ``exists()`` and ``exists_compiled()`` functions do not work on local variables or arguments.

E1006 E1041 E1167 E1168 E1213

Variables, functions and function arguments cannot shadow previously defined or imported variables and functions in the same script file.

Variables may shadow Ex commands, rename the variable if needed.

Global variables must be prefixed with "g:", also at the script level.

```
vim9script
var script_local = 'text'
g:global = 'value'
var Funcref = g:ThatFunction
```

Global functions must be prefixed with "g:":

```
vim9script
def g:GlobalFunc(): string
 return 'text'
enddef
echo g:GlobalFunc()
```

The "g:" prefix is not needed for auto-load functions.

vim9-function-defined-later

Although global functions can be called without the "g:" prefix, they must exist when compiled. By adding the "g:" prefix the function can be defined later. Example:

```
def CallPluginFunc()
 if exists('g:loaded_plugin')
 g:PluginFunc()
 endif
enddef
```

If you do it like this, you get an error at compile time that "PluginFunc" does not exist, even when "g:loaded\_plugin" does not exist:

```
def CallPluginFunc()
 if exists('g:loaded_plugin')
 PluginFunc() # Error - function not found
 endif
enddef
```

You can use `exists_compiled()` to avoid the error, but then the function would not be called, even when "g:loaded\_plugin" is defined later:

```
def CallPluginFunc()
 if exists_compiled('g:loaded_plugin')
 PluginFunc() # Function may never be called
 endif
enddef
```

Since ``&opt = value`` is now assigning a value to option "opt", ":%" cannot be used to repeat a ``:substitute`` command.

vim9-unpack-ignore

For an unpack assignment the underscore can be used to ignore a list item, similar to how a function argument can be ignored:

```
[a, _, c] = theList
```

To ignore any remaining items:

```
[a, b; _] = longList
```

E1163 E1080

Declaring more than one variable at a time, using the unpack notation, is possible. Each variable can have a type or infer it from the value:

```
var [v1: number, v2] = GetValues()
```

Use this only when there is a list with values, declaring one variable per line is much easier to read and change later.

## Constants

vim9-const vim9-final

How constants work varies between languages. Some consider a variable that can't be assigned another value a constant. JavaScript is an example. Others also make the value immutable, thus when a constant uses a list, the list cannot be changed. In Vim9 we can use both.

E1021 E1307

``:const`` is used for making both the variable and the value a constant. Use this for composite structures that you want to make sure will not be modified. Example:

```
const myList = [1, 2]
myList = [3, 4] # Error!
myList[0] = 9 # Error!
myList->add(3) # Error!
```

:final E1125

``:final`` is used for making only the variable a constant, the value can be changed. This is well known from Java. Example:

```
final myList = [1, 2]
myList = [3, 4] # Error!
myList[0] = 9 # OK
myList->add(3) # OK
```

It is common to write constants as ALL\_CAPS, but you don't have to.

The constant only applies to the value itself, not what it refers to.

```
final females = ["Mary"]
const NAMES = ["John", "Peter"], females]
NAMES[0] = ["Jack"] # Error!
NAMES[0][0] = "Jack" # Error!
NAMES[1] = ["Emma"] # Error!
NAMES[1][0] = "Emma" # OK, now females[0] == "Emma"
```

## Omitting `:call` and `:eval`

E1190

Functions can be called without ``:call``:

```
writefile(lines, 'file')
```

Using ``:call`` is still possible, but this is discouraged.

A method call without ``eval`` is possible, so long as the start is an

identifier or can't be an Ex command. For a function either "(" or "->" must be following, without a line break. Examples:

```
myList->add(123)
g:myList->add(123)
[1, 2, 3]->Process()
{a: 1, b: 2}->Process()
"foobar"->Process()
("foobar")->Process()
'foobar'->Process()
('foobar')->Process()
```

In the rare case there is ambiguity between a function name and an Ex command, prepend ":" to make clear you want to use the Ex command. For example, there is both the `:substitute` command and the `substitute()` function. When the line starts with `substitute()` this will use the function. Prepend a colon to use the command instead:

```
:substitute(pattern replacement (
```

If the expression starts with "!" this is interpreted as a shell command, not negation of a condition. Thus this is a shell command:

```
!shellCommand->something
```

Put the expression in parentheses to use the "!" for negation:

```
(!expression)->Method()
```

**Note** that while variables need to be defined before they can be used, functions can be called before being defined. This is required to allow for cyclic dependencies between functions. It is slightly less efficient, since the function has to be looked up by name. And a typo in the function name will only be found when the function is called.

### Omitting function()

A user defined function can be used as a function reference in an expression without `function()`. The argument types and return type will then be checked. The function must already have been defined.

```
var Funcref = MyFunction
```

When using `function()` the resulting type is "func", a function with any number of arguments and any return type (including void). The function can be defined later if the argument is in quotes.

### Lambda using => instead of ->

vim9-lambda

In legacy script there can be confusion between using "->" for a method call and for a lambda. Also, when a "{" is found the parser needs to figure out if it is the start of a lambda or a dictionary, which is now more complicated because of the use of argument types.

To avoid these problems Vim9 script uses a different syntax for a lambda, which is similar to JavaScript:

```
var Lambda = (arg) => expression
```

```
var Lambda = (arg): type => expression
```

E1157

No line break is allowed in the arguments of a lambda up to and including the "=>" (so that Vim can tell the difference between an expression in parentheses and lambda arguments). This is OK:

```
filter(list, (k, v) =>
 v > 0)
```

This does not work:

```
filter(list, (k, v)
 => v > 0)
```

This also does not work:

```
filter(list, (k,
 v) => v > 0)
```

But you can use a backslash to concatenate the lines before parsing:

```
filter(list, (k,
 \ v)
 \ => v > 0)
```

vim9-lambda-arguments E1172

In legacy script a lambda could be called with any number of extra arguments, there was no way to warn for not using them. In Vim9 script the number of arguments must match. If you do want to accept any arguments, or any further arguments, use "...\_", which makes the function accept

vim9-variable-arguments . Example:

```
var Callback = (..._) => 'anything'
echo Callback(1, 2, 3) # displays "anything"
```

inline-function E1171

Additionally, a lambda can contain statements in {}:

```
var Lambda = (arg) => {
 g:was_called = 'yes'
 return expression
}
```

This can be useful for a timer, for example:

```
var count = 0
var timer = timer_start(500, (_) => {
 count += 1
 echom 'Handler called ' .. count
}, {repeat: 3})
```

The ending "}" must be at the start of a line. It can be followed by other characters, e.g.:

```
var d = mapnew(dict, (k, v): string => {
 return 'value'
})
```

No command can follow the "{", only a comment can be used there.

command-block E1026

The block can also be used for defining a user command. Inside the block Vim9 syntax will be used.

This is an example of using here-docs:

```
com SomeCommand {
g:someVar =<< trim eval END
ccc
```

```

 ddd
 END
}

```

If the statements include a dictionary, its closing bracket must not be written at the start of a line. Otherwise, it would be parsed as the end of the block. This does not work:

```

command NewCommand {
 g:mydict = {
 'key': 'value',
 } # ERROR: will be recognized as the end of the block
}

```

Put the '}' after the last item to avoid this:

```

command NewCommand {
 g:mydict = {
 'key': 'value' }
}

```

Rationale: The "}" cannot be after a command because it would require parsing the commands to find it. For consistency with that no command can follow the "{". Unfortunately this means using "( ) => { command }" does not work, line breaks are always required.

[vim9-curly](#)

To avoid the "{" of a dictionary literal to be recognized as a statement block wrap it in parentheses:

```

var Lambda = (arg) => ({key: 42})

```

Also when confused with the start of a command block:

```

({
 key: value
})->method()

```

[Automatic line continuation](#)

[vim9-line-continuation](#) E1097

In many cases it is obvious that an expression continues on the next line. In those cases there is no need to prefix the line with a backslash (see [line-continuation](#)). For example, when a list spans multiple lines:

```

var mylist = [
 'one',
 'two',
]

```

And when a dict spans multiple lines:

```

var mydict = {
 one: 1,
 two: 2,
}

```

With a function call:

```

var result = Func(
 arg1,
 arg2
)

```

For binary operators in expressions not in [], {} or () a line break is possible just before or after the operator. For example:

```
var text = lead
 .. middle
 .. end
var total = start +
 end -
 correction
var result = positive
 ? PosFunc(arg)
 : NegFunc(arg)
```

For a method call using "->" and a member using a dot, a line break is allowed before it:

```
var result = GetBuilder()
 ->BuilderSetWidth(333)
 ->BuilderSetHeight(777)
 ->BuilderBuild()
var result = MyDict
 .member
```

For commands that have an argument that is a list of commands, the | character at the start of the line indicates line continuation:

```
autocmd BufNewFile *.match if condition
 | echo 'match'
 | endif
```

**Note** that this means that in heredoc the first line cannot start with a bar:

```
var lines =<< trim END
 | this doesn't work
END
```

Either use an empty line at the start or do not use heredoc. Or temporarily add the "C" flag to **'cptions'**:

```
set cpo+=C
var lines =<< trim END
 | this works
END
set cpo-=C
```

If the heredoc is inside a function **'cptions'** must be set before :def and restored after the :endef.

In places where line continuation with a backslash is still needed, such as splitting up a long Ex command, comments can start with '#\ ':

```
syn region Text
 \ start='foo'
 #\ comment
 \ end='bar'
```

Like with legacy script '"\ ' is used. This is also needed when line continuation is used without a backslash and a line starts with a bar:

```
au CursorHold * echom 'BEFORE bar'
 #\ some comment
 | echom 'AFTER bar'
```

E1050

To make it possible for the operator at the start of the line to be recognized, it is required to put a colon before a range. This example will add "start" and "print":

```
var result = start
+ print
```

Like this:

```
var result = start + print
```

This will assign "start" and print a line:

```
var result = start
:+ print
```

After the range an Ex command must follow. Without the colon you can call a function without `:call`, but after a range you do need it:

```
MyFunc()
:% call MyFunc()
```

**Note** that the colon is not required for the `+cmd` argument:

```
edit +6 fname
```

It is also possible to split a function header over multiple lines, in between arguments:

```
def MyFunc(
 text: string,
 separator = '-'
): string
```

Since a continuation line cannot be easily recognized the parsing of commands has been made stricter. E.g., because of the error in the first line, the second line is seen as a separate command:

```
popup_create(some invalid expression, {
 exit_cb: Func})
```

Now "exit\_cb: Func})" is actually a valid command: save any changes to the file "\_cb: Func})" and exit. To avoid this kind of mistake in Vim9 script there must be white space between most command names and the argument.

E1144

However, the argument of a command that is a command won't be recognized. For example, after "windo echo expr" a line break inside "expr" will not be seen.

#### Notes:

- "endif" cannot be used at the start of a continuation line, it ends the current function.
- No line break is allowed in the LHS of an assignment. Specifically when unpacking a list `:let-unpack`. This is OK:

```
[var1, var2] =
 Func()
```

This does not work:

```
[var1,
 var2] =
 Func()
```

- No line break is allowed in between arguments of an `:echo`, `:execute` and similar commands. This is OK:

```
echo [1,
 2] [3,
 4]
```

This does not work:

```
echo [1, 2]
 [3, 4]
```

- In some cases it is difficult for Vim to parse a command, especially when commands are used as an argument to another command, such as `:windo`. In those cases the line continuation with a backslash has to be used.

## White space

Vim9 script enforces proper use of white space. This is no longer allowed:

```
E1004 E1068 E1069 E1074 E1127 E1202
var name=234 # Error!
var name= 234 # Error!
var name =234 # Error!
```

There must be white space before and after the "=":

```
var name = 234 # OK
```

White space must also be put before the # that starts a comment after a command:

```
var name = 234# Error!
var name = 234 # OK
```

White space is required around most operators.

White space is required in a sublist (list slice) around the ":", except at the start and end:

```
otherlist = mylist[v : count] # v:count has a different meaning
otherlist = mylist[:] # make a copy of the List
otherlist = mylist[v :]
otherlist = mylist[: v]
```

White space is not allowed:

- Between a function name and the "(":

```
Func (arg) # Error!
Func
 \ (arg) # Error!
Func
 (arg) # Error!
Func(arg) # OK
Func(
 arg) # OK
Func(
 arg # OK
)
```

E1205

White space is not allowed in a `:set` command between the option name and a following "&", "!", "<", "=", "+=", "-=" or "^=".

## No curly braces expansion

`curly-braces-names` cannot be used.

## Command modifiers are not ignored

E1176

Using a command modifier for a command that does not use it gives an error.

E1082

Also, using a command modifier without a following command is now an error.

## Dictionary literals

vim9-literal-dict E1014

Traditionally Vim has supported dictionary literals with a `{}` syntax:

```
let dict = {'key': value}
```

Later it became clear that using a simple text key is very common, thus literal dictionaries were introduced in a backwards compatible way:

```
let dict = #{key: value}
```

However, this `#{}` syntax is unlike any existing language. As it turns out that using a literal key is much more common than using an expression, and considering that JavaScript uses this syntax, using the `{}` form for dictionary literals is considered a much more useful syntax. In Vim9 script the `{}` form uses literal keys:

```
var dict = {key: value}
```

This works for alphanumeric characters, underscore and dash. If you want to use another character, use a single or double quoted string:

```
var dict = {'key with space': value}
var dict = {"key\twith\ttabs": value}
var dict = {'': value} # empty key
```

E1139

In case the key needs to be an expression, square brackets can be used, just like in JavaScript:

```
var dict = [{"key" .. nr]: value}
```

The key type can be string, number, bool or float. Other types result in an error. Without using `[]` the value is used as a string, keeping leading zeros. An expression given with `[]` is evaluated and then converted to a string.

Leading zeros will then be dropped:

```
var dict = {000123: 'without', [000456]: 'with'}
echo dict
{'456': 'with', '000123': 'without'}
```

A float only works inside `[]` because the dot is not accepted otherwise:

```
var dict = {[00.013]: 'float'}
echo dict
{'0.013': 'float'}
```

## No `:xit`, `:t`, `:k`, `:append`, `:change` or `:insert`

E1100

These commands are too easily confused with local variable names.

Instead of ``:x`` or ``:xit`` you can use ``:exit``.

Instead of ``:t`` you can use ``:copy``.

Instead of ``:k`` you can use ``:mark``.

## Comparators

The **'ignorecase'** option is not used for comparators that use strings. Thus "`=~`" works like "`=~#`".

"is" and "isnot" ( `expr-is` and `expr-isnot` ) when used on strings now return false. In legacy script they just compare the strings, in Vim9 script they check identity, and strings are copied when used, thus two strings are never the same (this might change someday if strings are not copied but reference counted).

## Abort after error

In legacy script, when an error is encountered, Vim continues to execute following lines. This can lead to a long sequence of errors and need to type **CTRL-C** to stop it. In Vim9 script execution of commands stops at the first error. Example:

```
vim9script
var x = does-not-exist
echo 'not executed'
```

## For loop

E1254

The loop variable must not be declared yet:

```
var i = 1
for i in [1, 2, 3] # Error!
```

It is possible to use a global variable though:

```
g:i = 1
for g:i in [1, 2, 3]
 echo g:i
endfor
```

Legacy Vim script has some tricks to make a for loop over a list handle deleting items at the current or previous item. In Vim9 script it just uses the index, if items are deleted then items in the list will be skipped.

Example legacy script:

```
let l = [1, 2, 3, 4]
for i in l
 echo i
 call remove(l, index(l, i))
endfor
```

Would echo:

```
1
2
3
4
```

In compiled Vim9 script you get:

```
1
3
```

Generally, you should not change the list that is iterated over. Make a copy first if needed.

When looping over a list of lists, the nested lists can be changed. The loop variable is "final", it cannot be changed but what its value can be changed.

E1306

The depth of loops, :for and :while loops added together, cannot exceed 10.

## Conditions and expressions

vim9-boolean

Conditions and expressions are mostly working like they do in other languages. Some values are different from legacy Vim script:

value	legacy Vim script	Vim9 script
0	falsy	falsy
1	truthy	truthy
99	truthy	Error!
"0"	falsy	Error!
"99"	truthy	Error!
"text"	falsy	Error!

For the "??" operator and when using "!" then there is no error, every value is either falsy or truthy. This is mostly like JavaScript, except that an empty list and dict is falsy:

type	truthy when
bool	true, v:true or 1
number	non-zero
float	non-zero
string	non-empty
blob	non-empty
list	non-empty (different from JavaScript)
dictionary	non-empty (different from JavaScript)
func	when there is a function name
special	true or v:true
job	when not NULL
channel	when not NULL
class	when not NULL
object	when not NULL (TODO: when isTrue() returns true)

The boolean operators "||" and "&&" expect the values to be boolean, zero or one:

```
1 || false == true
0 || 1 == true
0 || false == false
1 && true == true
0 && 1 == false
8 || 0 Error!
'yes' && 0 Error!
[] || 99 Error!
```

When using "!" for inverting, there is no error for using any type and the result is a boolean. "!" can be used to turn any value into boolean:

```
!'yes' == false
![] == false
```

```
!![1, 2, 3] == true
```

When using "`.."` for string concatenation arguments of simple types are always converted to string:

```
'hello ' .. 123 == 'hello 123'
'hello ' .. v:true == 'hello true'
```

Simple types are Number, Float, Special and Bool. For other types `string()` should be used.

```
false true null null_blob null_channel
null_class null_dict null_function null_job
null_list null_object null_partial null_string
E1034
```

In Vim9 script one can use the following predefined values:

```
true
false
null
null_blob
null_channel
null_class
null_dict
null_function
null_job
null_list
null_object
null_partial
null_string
```

`true` is the same as `v:true`, `false` the same as `v:false`, `null` the same as `v:null`.

While `null` has the type "special", the other "null\_" values have the type indicated by their name. Quite often a null value is handled the same as an empty value, but not always. The values can be useful to clear a script-local variable, since they cannot be deleted with `:unlet`. E.g.:

```
var theJob = job_start(...)
let the job do its work
theJob = null_job
```

The values can also be useful as the default value for an argument:

```
def MyFunc(b: blob = null_blob)
Note: compare against null, not null_blob,
to distinguish the default value from an empty blob.
if b == null
b argument was not given
```

See [null-compare](#) for more information about testing against null.

It is possible to compare `null` with any value, this will not give a type error. However, comparing `null` with a number, float or bool will always result in `false`. This is different from legacy script, where comparing `null` with zero or `false` would return `true`.

[vim9-false-true](#)

When converting a boolean to a string `false` and `true` are used, not `v:false` and `v:true` like in legacy script. `v:none` has no `none` replacement, it has no equivalent in other languages.

## vim9-string-index

Indexing a string with `[idx]` or taking a slice with `[idx : idx]` uses character indexes instead of byte indexes. Composing characters are included.

Example:

```
echo 'bár'[1]
```

In legacy script this results in the character `0xc3` (an illegal byte), in Vim9 script this results in the string `'á'`.

A negative index is counting from the end, `"[-1]"` is the last character.

To exclude the last character use `slice()`.

To count composing characters separately use `strcharpart()`.

If the index is out of range then an empty string results.

In legacy script `"++var"` and `"--var"` would be silently accepted and have no effect. This is an error in Vim9 script.

Numbers starting with zero are not considered to be octal, only numbers starting with `"0o"` are octal: `"0o744"`. [scriptversion-4](#)

## What to watch out for

### vim9-gotchas

Vim9 was designed to be closer to often used programming languages, but at the same time tries to support the legacy Vim commands. Some compromises had to be made. Here is a summary of what might be unexpected.

Ex command ranges need to be prefixed with a colon.

<code>-&gt;</code>	legacy Vim: shifts the previous line to the right
<code>-&gt;func()</code>	Vim9: method call in a continuation line
<code>:-&gt;</code>	Vim9: shifts the previous line to the right
<code>%s/a/b</code>	legacy Vim: substitute on all lines
<code>x = alongname</code>	
<code>% another</code>	Vim9: modulo operator in a continuation line
<code>:%s/a/b</code>	Vim9: substitute on all lines
<code>'t</code>	legacy Vim: jump to mark t
<code>'text'-&gt;func()</code>	Vim9: method call
<code>:'t</code>	Vim9: jump to mark t

Some Ex commands can be confused with assignments in Vim9 script:

<code>g:name = value</code>	# assignment
<code>g:pattern:cmd</code>	# :global command

To avoid confusion between a ``:global`` or ``:substitute`` command and an expression or assignment, a few separators cannot be used when these commands are abbreviated to a single character: `':'`, `'-'` and `'.'`.

<code>g:pattern:cmd</code>	# invalid command - ERROR
<code>s:pattern:repl</code>	# invalid command - ERROR
<code>g-pattern-cmd</code>	# invalid command - ERROR
<code>s-pattern-repl</code>	# invalid command - ERROR
<code>g.pattern.cmd</code>	# invalid command - ERROR
<code>s.pattern.repl</code>	# invalid command - ERROR

Also, there cannot be a space between the command and the separator:

<code>g /pattern/cmd</code>	# invalid command - ERROR
-----------------------------	---------------------------

```
s /pattern/repl # invalid command - ERROR
```

Functions defined with `:def` compile the whole function. Legacy functions can bail out, and the following lines are not parsed:

```
func Maybe()
 if !has('feature')
 return
 endif
 use-feature
endfunc
```

Vim9 functions are compiled as a whole:

```
def Maybe()
 if !has('feature')
 return
 endif
 use-feature # May give a compilation error
enddef
```

For a workaround, split it in two functions:

```
func Maybe()
 if has('feature')
 call MaybeInner()
 endif
endfunc
if has('feature')
 def MaybeInner()
 use-feature
 enddef
endif
```

Or put the unsupported code inside an `if` with a constant expression that evaluates to false:

```
def Maybe()
 if has('feature')
 use-feature
 endif
enddef
```

The `exists_compiled()` function can also be used for this.

[vim9-user-command](#)

Another side effect of compiling a function is that the presence of a user command is checked at compile time. If the user command is defined later an error will result. This works:

```
command -nargs=1 MyCommand echom <q-args>
def Works()
 MyCommand 123
enddef
```

This will give an error for "MyCommand" not being defined:

```
def Works()
 command -nargs=1 MyCommand echom <q-args>
 MyCommand 123
enddef
```

A workaround is to invoke the command indirectly with `:execute`:

```
def Works()
 command -nargs=1 MyCommand echom <q-args>
 execute 'MyCommand 123'
enddef
```

Note that for unrecognized commands there is no check for "|" and a following command. This will give an error for missing `endif`:

```
def Maybe()
 if has('feature') | use-feature | endif
enddef
```

### Other differences

Patterns are used like **'magic'** is set, unless explicitly overruled.

The **'edcompatible'** option value is not used.

The **'gdefault'** option value is not used.

You may also find this wiki useful. It was written by an early adopter of Vim9 script: <https://github.com/lacygoill/wiki/blob/master/vim/vim9.md>

The ++ and -- commands have been added. They are very similar to adding or subtracting one:

```
++var
var += 1
--var
var -= 1
```

Using ++var or --var in an expression is not supported yet.

---

### 3. New style functions

#### fast-functions

```
:def[!] {name}([arguments])[: {return-type}]
```

**:def** E1028

Define a new function by the name **{name}**. The body of the function follows in the next lines, until the matching **:enddef**. E1073

E1011

The **{name}** must be less than 100 bytes long.

E1003 E1027 E1056 E1059

The type of value used with **:return** must match **{return-type}**. When **{return-type}** is omitted or is "void" the function is not expected to return anything.

E1077 E1123

**{arguments}** is a sequence of zero or more argument declarations. There are three forms:

```
{name}: {type}
{name} = {value}
{name}: {type} = {value}
```

The first form is a mandatory argument, the caller must always provide them.

The second and third form are optional arguments.

When the caller omits an argument the **{value}** is used.

The function will be compiled into instructions when

called, or when `:disassemble` or `:defcompile` is used. Syntax and type errors will be produced at that time.

It is possible to nest `:def` inside another `:def` or `:function` up to about 50 levels deep.

E1117

[!] is used as with `:function`. Note that script-local functions cannot be deleted or redefined later in Vim9 script. They can only be removed by reloading the same script.

`:enddef` E1057 E1152 E1173

`:enddef` End of a function defined with `:def`. It should be on a line by its own.

You may also find this wiki useful. It was written by an early adopter of Vim9 script: <https://github.com/lacygoill/wiki/blob/master/vim/vim9.md>

If the script the function is defined in is Vim9 script, then script-local variables can be accessed without the "s:" prefix. They must be defined before the function is compiled. If the script the function is defined in is legacy script, then script-local variables must be accessed with the "s:" prefix if they do not exist at the time of compiling.

E1269

Script-local variables in a Vim9 script must be declared at the script level. They cannot be created in a function, also not in a legacy function.

`:defc` `:defcompile`

`:defc[ompile]` Compile functions and classes (`class-compile`) defined in the current script that were not compiled yet. This will report any errors found during compilation.

`:defc[ompile] MyClass` Compile all methods in a class. `class-compile`

`:defc[ompile] {func}`

`:defc[ompile] debug {func}`

`:defc[ompile] profile {func}`

Compile function `{func}`, if needed. Use "debug" and "profile" to specify the compilation mode. This will report any errors found during compilation. `{func}` call also be "ClassName.functionName" to compile a function or method in a class. `{func}` call also be "ClassName" to compile all functions and methods in a class.

`:disa` `:disassemble`

`:disa[ssemble] {func}` Show the instructions generated for `{func}`.

This is for debugging and testing. E1061

Note that for command line completion of `{func}` you can prepend "s:" to find script-local functions.

`:disa[ssemble] profile {func}`

Like `:disassemble` but with the instructions used for profiling.

```
:disa[ssemble] debug {func}
```

Like `:disassemble` but with the instructions used for debugging.

## Limitations

Local variables will not be visible to string evaluation. For example:

```
def MapList(): list<string>
 var list = ['aa', 'bb', 'cc', 'dd']
 return range(1, 2)->map('list[v:val]')
enddef
```

The map argument is a string expression, which is evaluated without the function scope. Instead, use a lambda:

```
def MapList(): list<string>
 var list = ['aa', 'bb', 'cc', 'dd']
 return range(1, 2)->map((_, v) => list[v])
enddef
```

For commands that are not compiled, such as `:edit`, backtick expansion can be used and it can use the local scope. Example:

```
def Replace()
 var fname = 'blah.txt'
 edit `=fname`
enddef
```

Closures defined in a loop will share the same context. For example:

```
var flist: list<func>
for i in range(5)
 var inloop = i
 flist[i] = () => inloop
endfor
echo range(5)->map((i, _) => flist[i]())
Result: [4, 4, 4, 4, 4]
```

E1271

A closure must be compiled in the context that it is defined in, so that variables in that context can be found. This mostly happens correctly, except when a function is marked for debugging with `:breakadd` after it was compiled. Make sure to define the breakpoint before compiling the outer function.

The "inloop" variable will exist only once, all closures put in the list refer to the same instance, which in the end will have the value 4. This is efficient, also when looping many times. If you do want a separate context for each closure, call a function to define it:

```
def GetClosure(i: number): func
 var infunc = i
 return () => infunc
enddef

var flist: list<func>
for i in range(5)
```

```

 flist[i] = GetClosure(i)
endfor
echo range(5)->map((i, _) => flist[i]())
Result: [0, 1, 2, 3, 4]

```

In some situations, especially when calling a Vim9 closure from legacy context, the evaluation will fail. [E1248](#)

**Note** that at the script level the loop variable will be invalid after the loop, also when used in a closure that is called later, e.g. with a timer. This will generate error [E1302](#) :

```

for n in range(4)
 timer_start(500 * n, (_) => {
 echowin n
 })
endfor

```

You need to use a block and define a variable there, and use that one in the closure:

```

for n in range(4)
{
 var nr = n
 timer_start(500 * n, (_) => {
 echowin nr
 })
}
endfor

```

Using ``:echowindow`` is useful in a timer, the messages go into a popup and will not interfere with what the user is doing when it triggers.

### Converting a function from legacy to Vim9

#### [convert\\_legacy\\_function\\_to\\_vim9](#)

These are the most changes that need to be made to convert a legacy function to a Vim9 function:

- Change ``func`` or ``function`` to ``def``.
- Change ``endfunc`` or ``endfunction`` to ``enddef``.
- Add types to the function arguments.
- If the function returns something, add the return type.
- Change comments to start with `#` instead of `"`.

For example, a legacy function:

```

func MyFunc(text)
 " function body
endfunc

```

Becomes:

```

def MyFunc(text: string): number
 # function body
enddef

```

- Remove `"a:"` used for arguments. E.g.:  

```
return len(a:text)
```

Becomes:

```
return len(text)
```

- Change ``let`` used to declare a variable to ``var``.
- Remove ``let`` used to assign a value to a variable. This is for local variables already declared and b: w: g: and t: variables.

For example, legacy function:

```
let lnum = 1
let lnum += 3
let b:result = 42
```

Becomes:

```
var lnum = 1
lnum += 3
b:result = 42
```

- Insert white space in expressions where needed.
- Change ``.`` used for concatenation to ``.``.

For example, legacy function:

```
echo line(1).line(2)
```

Becomes:

```
echo line(1) .. line(2)
```

- line continuation does not always require a backslash:

```
echo ['one',
 \ 'two',
 \ 'three'
 \]
```

Becomes:

```
echo ['one',
 'two',
 'three'
]
```

## Calling a function in an expr option

[expr-option-function](#)

The value of a few options, such as `'foldexpr'`, is an expression that is evaluated to get a value. The evaluation can have quite a bit of overhead. One way to minimize the overhead, and also to keep the option value very simple, is to define a compiled function and set the option to call it without arguments. Example:

```
vim9script
def MyFoldFunc(): any
 ... compute fold level for line v:lnum
 return level
enddef
set foldexpr=s:MyFoldFunc()
```

---

## 4. Types

[vim9-types](#)

[E1008](#) [E1009](#) [E1010](#) [E1012](#)

The following builtin types are supported:

```
bool
number
float
string
blob
list<{type}>
dict<{type}>
job
channel
func
func: {type}
func({type}, ...)
func({type}, ...): {type}
void
```

Not supported yet:

```
tuple<a: {type}, b: {type}, ...>
```

These types can be used in declarations, but no simple value will actually have the "void" type. Trying to use a void (e.g. a function without a return value) results in error [E1031](#) [E1186](#) .

There is no array type, use `list<{type}>` instead. For a list constant an efficient implementation is used that avoids allocating a lot of small pieces of memory.

A partial and function can be declared in more or less specific ways:

<code>func</code>	any kind of function reference, no type checking for arguments or return value
<code>func: void</code>	any number and type of arguments, no return value
<code>func: {type}</code>	any number and type of arguments with specific return type
<code>func()</code>	function with no argument, does not return a value
<code>func(): void</code>	same
<code>func(): {type}</code>	function with no argument and return type
<code>func({type})</code>	function with argument type, does not return a value
<code>func({type}): {type}</code>	function with argument type and return type
<code>func({type})</code>	function with type of optional argument, does not return a value
<code>func(...list&lt;{type}&gt;)</code>	function with type of list for variable number of arguments, does not return a value
<code>func({type}, ?{type}, ...list&lt;{type}&gt;): {type}</code>	function with: <ul style="list-style-type: none"> <li>- type of mandatory argument</li> <li>- type of optional argument</li> <li>- type of list for variable number of arguments</li> </ul>

- return type

If the return type is "void" the function does not return a value.

The reference can also be a `Partial`, in which case it stores extra arguments and/or a dictionary, which are not visible to the caller. Since they are called in the same way the declaration is the same.

Custom types can be defined with `:type``:

```
:type MyList list<string>
```

Custom types must start with a capital letter, to avoid name clashes with builtin types added later, similarly to user functions.

And classes and interfaces can be used as types:

```
:class MyClass
:var mine: MyClass
```

```
:interface MyInterface
:var mine: MyInterface
```

```
:class MyTemplate<Targ>
:var mine: MyTemplate<number>
:var mine: MyTemplate<string>
```

```
:class MyInterface<Targ>
:var mine: MyInterface<number>
:var mine: MyInterface<string>
```

{not implemented yet}

## Variable types and type casting

variable-types

Variables declared in Vim9 script or in a `:def`` function have a type, either specified explicitly or inferred from the initialization.

Global, buffer, window and tab page variables do not have a specific type, the value can be changed at any time, possibly changing the type. Therefore, in compiled code the "any" type is assumed.

This can be a problem when the "any" type is undesired and the actual type is expected to always be the same. For example, when declaring a list:

```
var l: list<number> = [1, g:two]
```

At compile time Vim doesn't know the type of "g:two" and the expression type becomes list<any>. An instruction is generated to check the list type before doing the assignment, which is a bit inefficient.

type-casting E1104

To avoid this, use a type cast:

```
var l: list<number> = [1, <number>g:two]
```

The compiled code will then only check that "g:two" is a number and give an error if it isn't. This is called type casting.

The syntax of a type cast is: `"<" {type} ">"`. There cannot be white space after the `"<"` or before the `">"` (to avoid them being confused with smaller-than and bigger-than operators).

The semantics is that, if needed, a runtime type check is performed. The value is not actually changed. If you need to change the type, e.g. to change it to a string, use the `string()` function. Or use `str2nr()` to convert a string to a number.

If a type is given where it is not expected you can get `E1272` .

If a type is incomplete you get `E1363` , e.g. when you have an object for which the class is not known (usually that is a null object).

## Type inference

### type-inference

In general: Whenever the type is clear it can be omitted. For example, when declaring a variable and giving it a value:

```
var name = 0 # infers number type
var name = 'hello' # infers string type
```

The type of a list and dictionary comes from the common type of the values. If the values all have the same type, that type is used for the list or dictionary. If there is a mix of types, the "any" type is used.

```
[1, 2, 3] list<number>
['a', 'b', 'c'] list<string>
[1, 'x', 3] list<any>
```

The common type of function references, if they do not all have the same number of arguments, uses "(...)" to indicate the number of arguments is not specified. For example:

```
def Foo(x: bool)
enddef
def Bar(x: bool, y: bool)
enddef
var funclist = [Foo, Bar]
echo funclist->typename()
```

Results in:

```
list<func(...)>
```

For script-local variables in Vim9 script the type is checked, also when the variable was declared in a legacy function.

When a type has been declared this is attached to a List or Dictionary. When later some expression attempts to change the type an error will be given:

```
var ll: list<number> = [1, 2, 3]
ll->extend(['x']) # Error, 'x' is not a number
```

If the type is not declared then it is allowed to change:

```
[1, 2, 3]->extend(['x']) # result: [1, 2, 3, 'x']
```

For a variable declaration an inferred type matters:

```
var ll = [1, 2, 3]
ll->extend(['x']) # Error, 'x' is not a number
```

That is because the declaration looks like a list of numbers, thus is equivalent to:

```
var ll: list<number> = [1, 2, 3]
```

If you do want a more permissive list you need to declare the type:

```
var ll: list<any> = [1, 2, 3]
ll->extend(['x']) # OK
```

## Stricter type checking

### type-checking

In legacy Vim script, where a number was expected, a string would be automatically converted to a number. This was convenient for an actual number such as "123", but leads to unexpected problems (and no error message) if the string doesn't start with a number. Quite often this leads to hard-to-find bugs. e.g.:

```
echo 123 == '123'
```

```
1
```

With an accidental space:

```
echo 123 == ' 123'
```

```
0
```

In Vim9 script this has been made stricter. In most places it works just as before if the value used matches the expected type. There will sometimes be an error, thus breaking backwards compatibility. For example:

- Using a number other than 0 or 1 where a boolean is expected. E1023
- Using a string value when setting a number option. E1206 E1210 E1212
- Using a number where a string is expected. E1024 E1105

One consequence is that the item type of a list or dict given to `map()` must not change, if the type was declared. This will give an error in Vim9 script:

```
var mylist: list<number> = [1, 2, 3]
echo map(mylist, (i, v) => 'item ' .. i)
E1012: Type mismatch; expected number but got string in map()
```

Instead use `mapnew()`, it creates a new list:

```
var mylist: list<number> = [1, 2, 3]
echo mapnew(mylist, (i, v) => 'item ' .. i)
['item 0', 'item 1', 'item 2']
```

If the item type was not declared or determined to be "any" it can change to a more specific type. E.g. when a list of mixed types gets changed to a list of strings:

```
var mylist = [1, 2.0, '3']
typename(mylist) == "list<any>"
map(mylist, (i, v) => 'item ' .. i)
typename(mylist) == "list<string>", no error
```

There is a subtle difference between using a list constant directly and through a variable declaration. Because of type inference, when using a list constant to initialize a variable, this also sets the declared type:

```
var mylist = [1, 2, 3]
typename(mylist) == "list<number>"
echo map(mylist, (i, v) => 'item ' .. i) # Error!
```

When using the list constant directly, the type is not declared and is allowed to change:

```
echo map([1, 2, 3], (i, v) => 'item ' .. i) # OK
```

The reasoning behind this is that when a type is declared and the list is passed around and changed, the declaration must always hold. So that you can rely on the type to match the declared type. For a constant this is not needed.

E1158

Same for `extend()`, use `extendnew()` instead, and for `flatten()`, use `flattennew()` instead. Since `flatten()` is intended to always change the type, it can not be used in Vim9 script.

Assigning to a funcref with specified arguments (see [vim9-func-declaration](#)) does strict type checking of the arguments. For variable number of arguments the type must match:

```
var FuncRef: func(string, number, bool): number
FuncRef = (v1: string, v2: number, v3: bool) => 777 # OK
FuncRef = (v1: string, v2: number, v3: number) => 777 # Error!
variable number of arguments must have same type
var FuncVA: func(...list<string>): number
FuncVA = (...v: list<number>): number => v # Error!
FuncVA = (...v: list<any>): number => v # OK, `any` runtime check
FuncVA = (v1: string, v: string2): number => 333 # Error!
FuncVA = (v: list<string>): number => 3 # Error!
```

If the destination funcref has no specified arguments, then there is no argument type checking:

```
var FuncUnknownArgs: func: number
FuncUnknownArgs = (v): number => v # OK
FuncUnknownArgs = (v1: string, v2: string): number => 3 # OK
FuncUnknownArgs = (...v1: list<string>): number => 333 # OK
```

```
E1211 E1217 E1218 E1219 E1220 E1221
E1222 E1223 E1224 E1225 E1226 E1227
E1228 E1238 E1250 E1251 E1252 E1256
E1297 E1298 E1301
```

Types are checked for most builtin functions to make it easier to spot mistakes.

### Categories of variables, defaults and null handling

variable-categories null-variables

There are categories of variables:

```
primitive number, float, boolean
container string, blob, list, dict
specialized function, job, channel, user-defined-object
```

When declaring a variable without an initializer, an explicit type must be provided. Each category has different default initialization semantics. Here's an example for each category:

```
var num: number # primitives default to a 0 equivalent
var cont: list<string> # containers default to an empty container
var spec: job # specialized variables default to null
```

Vim does not have a familiar null value; it has various `null_<type>` predefined

values, for example [null\\_string](#) , [null\\_list](#) , [null\\_job](#) . Primitives do not have a `null_<type>`. The typical use cases for `null_<type>` are:

- to clear a variable and release its resources;
- as a default for a parameter in a function definition, see [null-compare](#) .

For a specialized variable, like ``job``, `null_<type>` is used to clear the resources. For a container variable, resources can also be cleared by assigning an empty container to the variable. For example:

```
var j: job = job_start(...)
... job does its work
j = null_job # clear the variable and release the job's resources

var l: list<any>
... add lots of stuff to list
l = [] # clear the variable and release container resources
```

Using the empty container, rather than `null_<type>`, to clear a container variable may avoid null complications as described in [null-anomalies](#) .

The initialization semantics of container variables and specialized variables differ. An uninitialized container defaults to an empty container:

```
var l1: list<string> # empty container
var l2: list<string> = [] # empty container
var l3: list<string> = null_list # null container
```

"l1" and "l2" are equivalent and indistinguishable initializations; but "l3" is a null container. A null container is similar to, but different from, an empty container, see [null-anomalies](#) .

Specialized variables default to null. These job initializations are equivalent and indistinguishable:

```
var j1: job
var j2: job = null_job
var j3 = null_job
```

When a list or dict is declared, if the item type is not specified and can not be inferred, then the type is "any":

```
var d1 = {} # type is "dict<any>"
var d2 = null_dict # type is "dict<any>"
```

Declaring a function, see [vim9-func-declaration](#) , is particularly unique.

#### [null-compare](#)

For familiar null compare semantics, where a null container is not equal to an empty container, do not use `null_<type>` in a comparison:

```
vim9script
def F(arg: list<string> = null_list)
 if arg == null
 echo "null"
 else
 echo printf("not null, %sempty", empty(arg) ? '' : 'not ')
 endif
enddef
F() # output: "null"
F(null_list) # output: "null"
F([]) # output: "not null, empty"
```

```
F(['']) # output: "not null, not empty"
```

The above function takes a list of strings and reports on it.

Change the above function signature to accept different types of arguments:

```
def F(arg: list<any> = null_list) # any type of list
def F(arg: any = null) # any type
```

In the above example, where the goal is to distinguish a null list from an empty list, comparing against ``null`` instead of ``null_list`` is the correct choice. The basic reason is because `"null_list == null"` and `"[] != null"`. Comparing to ``null_list`` fails since `"[] == null_list"`. In the following section there are details about comparison results.

### null-details null-anomalies

This section describes issues about using null and null\_<type>; included below are the enumerated results of null comparisons. In some cases, if familiar with vim9 null semantics, the programmer may chose to use null\_<type> in comparisons and/or other situations.

Elsewhere in the documentation it says:

```
Quite often a null value is handled the same as an empty value, but
not always
```

Here's an example:

```
vim9script
var s1: list<string>
var s2: list<string> = null_list
echo s1 # output: "[]"
echo s2 # output: "[]"

echo s1 + ['a'] # output: "['a']"
echo s2 + ['a'] # output: "['a']"

echo s1->add('a') # output: "['a']"
echo s2->add('a') # E1130: Can not add to null list
```

Two values equal to a null\_<type> are not necessarily equal to each other:

```
vim9script
echo {} == null_dict # true
echo null_dict == null # true
echo {} == null # false
```

Unlike the other containers, an uninitialized string is equal to null. The `'is'` operator can be used to determine if it is a null\_string:

```
vim9script
var s1: string
var s2 = null_string
echo s1 == null # true - this is unexpected
echo s2 == null # true
echo s2 is null_string # true

var b1: blob
var b2 = null_blob
echo b1 == null # false
echo b2 == null # true
```

Any variable initialized to the `null_<type>` is equal to the `null_<type>` and is also equal to `null`. For example:

```
vim9script
var x = null_blob
echo x == null_blob # true
echo x == null # true
```

An uninitialized variable is usually equal to `null`; it depends on its type:

```
var s: string s == null
var b: blob b != null ***
var l: list<any> l != null ***
var d: dict<any> d != null ***
var f: func f == null
var j: job j == null
var c: channel c == null
var o: Class o == null
```

A variable initialized to empty equals `null_<type>`; but not `null`:

```
var s2: string = "" == null_string != null
var b2: blob = 0z == null_blob != null
var l2: list<any> = [] == null_list != null
var d2: dict<any> = {} == null_dict != null
```

**NOTE:** the specialized variables, like `job`, default to `null` value and have no corresponding empty value.

---

## 5. Namespace, Import and Export

`vim9script`   `vim9-export`   `vim9-import`

A Vim9 script can be written to be imported. This means that some items are intentionally exported, made available to other scripts. When the exporting script is imported in another script, these exported items can then be used in that script. All the other items remain script-local in the exporting script and cannot be accessed by the importing script.

This mechanism exists for writing a script that can be sourced (imported) by other scripts, while making sure these other scripts only have access to what you want them to. This also avoids using the global namespace, which has a risk of name collisions. For example when you have two plugins with similar functionality.

You can cheat by using the global namespace explicitly. That should be done only for things that really are global.

### Namespace

`vim9-namespace`

To recognize a file that can be imported the ``vim9script`` statement must appear as the first statement in the file (see `vim9-mix` for an exception). It tells Vim to interpret the script in its own namespace, instead of the global namespace. If a file starts with:

```
vim9script
```

```
var myvar = 'yes'
```

Then "myvar" will only exist in this file. While without ``vim9script`` it would be available as ``g:myvar`` from any other script and function.

E1101

The variables at the file level are very much like the script-local "s:" variables in legacy Vim script, but the "s:" is omitted. And they cannot be deleted.

In Vim9 script the global "g:" namespace can still be used as before. And the "w:", "b:" and "t:" namespaces. These have in common that variables are not declared, have no specific type and they can be deleted. E1304

A side effect of ``:vim9script`` is that the `'coptions'` option is set to the Vim default value, like with:

```
:set cpo&vim
```

One of the effects is that `line-continuation` is always enabled.

The original value of `'coptions'` is restored at the end of the script, while flags added or removed in the script are also added to or removed from the original value to get the same effect. The order of flags may change.

In the `vimrc` file sourced on startup this does not happen.

vim9-mix

There is one way to use both legacy and Vim9 syntax in one script file:

```
" comments may go here
if !has('vim9script')
 " legacy script commands go here
 finish
endif
vim9script
Vim9 script commands go here
```

This allows for writing a script that takes advantage of the Vim9 script syntax if possible, but will also work on a `Vim version without` it.

**Note** that Vim9 syntax changed before Vim 9 so that scripts using the current syntax (such as "import from" instead of "import") might throw errors. To prevent these, a safer check could be for `v:version >= 900` instead.

This can only work in two ways:

1. The "if" statement evaluates to false, the commands up to ``endif`` are skipped and ``vim9script`` is then the first command actually executed.
2. The "if" statement evaluates to true, the commands up to ``endif`` are executed and ``finish`` bails out before reaching ``vim9script``.

## Export

```
:export :exp
```

Exporting an item can be written as:

```
export const EXPORTED_CONST = 1234
export var someValue = ...
export final someValue = ...
export const someValue = ...
export def MyFunc() ...
export class MyClass ...
export interface MyClass ...
```

```
export enum MyEnum ...
```

E1043 E1044

As this suggests, only constants, variables, `:def` functions, classes, interfaces and enums can be exported.`

E1042

`:export` can only be used in Vim9 script, at the script level.`

## Import

```
:import :imp E1094 E1047 E1262
E1048 E1049 E1053 E1071 E1088 E1236
```

The exported items can be imported in another script. The import syntax has two forms. The simple form:

```
import {filename}
```

Where `{filename}` is an expression that must evaluate to a string. In this form the filename should end in ".vim" and the portion before ".vim" will become the script local name of the namespace. For example:

```
import "myscript.vim"
```

This makes each exported item in "myscript.vim" available as "myscript.item".

:import-as E1257 E1261

In case the name is long or ambiguous, this form can be used to specify another name:

```
import {longfilename} as {name}
```

In this form `{name}` becomes a specific script local name for the imported namespace. Therefore `{name}` must consist of letters, digits and '\_', like `internal-variables`. The `{longfilename}` expression must evaluate to any filename. For example:

```
import "thatscript.vim.v2" as that
```

E1060 E1258 E1259 E1260

Then you can use "that.item", etc. You are free to choose the name "that". Use something that will be recognized as referring to the imported script. Avoid command names, command modifiers and builtin function names, because the name will shadow them. It's better not to start the name with a capital letter, since it can then also shadow global user commands and functions. Also, you cannot use the name for something else in the script, such as a function or variable name.

In case the dot in the name is undesired, a local reference can be made for a function:

```
var LongFunc = that.LongFuncName
```

This also works for constants:

```
const MAXLEN = that.MAX_LEN_OF_NAME
```

This does not work for variables, since the value would be copied once and when changing the variable the copy will change, not the original variable. You will need to use the full name, with the dot.

`:import` can not be used in a function. Imported items are intended to exist at the script level and only imported once.`

The script name after ``import`` can be:

- A relative path, starting "." or "..". This finds a file relative to the location of the script file itself. This is useful to split up a large plugin into several files.
- An absolute path, starting with "/" on Unix or "D:/" on MS-Windows. This will rarely be used.
- A path not being relative or absolute. This will be found in the "import" subdirectories of `'runtimepath'` entries. The name will usually be longer and unique, to avoid loading the wrong file.  
`Note` that "after/import" is not used.

If the name does not end in ".vim" then the use of "as name" is required.

Once a vim9 script file has been imported, the result is cached and used the next time the same script is imported. It will not be read again.

It is not allowed to import the same script twice, also when using two different "as" names.

When using the imported name the dot and the item name must be in the same line, there can be no line break:

```
echo that.
 name # Error!
echo that
 .name # Error!
```

`import-map`

When you've imported a function from one script into a vim9 script you can refer to the imported function in a mapping by prefixing it with `<SID>` :

```
noremap <silent> ,a :call <SID>name.Function()<CR>
```

When the mapping is defined "`<SID>name.`" will be replaced with `<SNR>` and the script ID of the imported script.

An even simpler solution is using `<ScriptCmd>` :

```
noremap ,a <ScriptCmd>name.Function()<CR>
```

`Note` that this does not work for variables, only for functions.

`import-legacy` `legacy-import`

``:import`` can also be used in legacy Vim script. The imported namespace still becomes script-local, even when the "s:" prefix is not given. For example:

```
import "myfile.vim"
call s:myfile.MyFunc()
```

And using the "as name" form:

```
import "otherfile.vim9script" as that
call s:that.OtherFunc()
```

However, the namespace cannot be resolved on its own:

```
import "that.vim"
echo s:that
" ERROR: E1060: Expected dot after name: s:that
```

This also affects the use of `<SID>` in the legacy mapping context. Since

<SID> is only a valid prefix for a function and NOT for a namespace, you cannot use it to scope a function in a script local namespace. Instead of prefixing the function with <SID> you should use <ScriptCmd> . For example:

```
noremap ,a <ScriptCmd>:call s:that.OtherFunc()<CR>
```

**:import-cycle**

The ``import`` commands are executed when encountered. If script A imports script B, and B (directly or indirectly) imports A, this will be skipped over. At this point items in A after "import B" will not have been processed and defined yet. Therefore cyclic imports can exist and not result in an error directly, but may result in an error for items in A after "import B" not being defined. This does not apply to autoload imports, see the next section.

### Importing an autoload script

**vim9-autoload import-autoload**

For optimal startup speed, loading scripts should be postponed until they are actually needed. Using the autoload mechanism is recommended:

**E1264**

1. In the plugin define user commands, functions and/or mappings that refer to items imported from an autoload script.

```
import autoload 'for/search.vim'
command -nargs=1 SearchForStuff search.Stuff(<f-args>)
```

This goes in `.../plugin/anyname.vim`. "anyname.vim" can be freely chosen. The "SearchForStuff" command is now available to the user.

The "autoload" argument to ``:import`` means that the script is not loaded until one of the items is actually used. The script will be found under the "autoload" directory in `'runtimepath'` instead of the "import" directory. Alternatively a relative or absolute name can be used, see below.

2. In the autoload script put the bulk of the code.

```
vim9script
export def Stuff(arg: string)
...
...
```

This goes in `.../autoload/for/search.vim`.

Putting the "search.vim" script under the `"/autoload/for/"` directory has the effect that `"for#search#"` will be prefixed to every exported item. The prefix is obtained from the file name, as you would to manually in a legacy autoload script. Thus the exported function can be found with `"for#search#Stuff"`, but you would normally use ``import autoload`` and not use the prefix (which has the side effect of loading the autoload script when compiling a function that encounters this name).

You can split up the functionality and import other scripts from the autoload script as you like. This way you can share code between plugins.

Searching for the autoload script in all entries in `'runtimepath'` can be a bit slow. If the plugin knows where the script is located, quite often a relative

path can be used. This avoids the search and should be quite a bit faster. Another advantage is that the script name does not need to be unique. An absolute path is also possible. Examples:

```
import autoload './lib/implement.vim'
import autoload MyScriptsDir .. '/lib/implement.vim'
```

For defining a mapping that uses the imported autoload script the special key `<ScriptCmd>` is useful. It allows for a command in a mapping to use the script context of where the mapping was defined.

When compiling a `:def` function and a function in an autoload script is encountered, the script is not loaded until the `:def` function is called. This also means you get any errors only at runtime, since the argument and return types are not known yet. If you would use the name with '#' characters then the autoload script IS loaded.

Be careful to not refer to an item in an autoload script that does trigger loading it unintentionally. For example, when setting an option that takes a function name, make sure to use a string, not a function reference:

```
import autoload 'qftf.vim'
&quickfixtextfunc = 'qftf.Func' # autoload script NOT loaded
&quickfixtextfunc = qftf.Func # autoload script IS loaded
```

On the other hand, it can be useful to load the script early, at a time when any errors should be given.

For testing the `test_override()` function can be used to have the `import autoload` load the script right away, so that the items and types can be checked without waiting for them to be actually used:

```
test_override('autoload', 1)
```

Reset it later with:

```
test_override('autoload', 0)
```

Or:

```
test_override('ALL', 0)
```

---

## 6. Classes and interfaces

[vim9-classes](#)

In legacy script a Dictionary could be used as a kind-of object, by adding members that are functions. However, this is quite inefficient and requires the writer to do the work of making sure all the objects have the right members. See [Dictionary-function](#).

In [Vim9](#) script you can have classes, objects and interfaces like in most popular object-oriented programming languages. Since this is a lot of functionality it is located in a separate help file: [vim9class.txt](#).

---

## 9. Rationale

[vim9-rationale](#)

The `:def` command

Plugin writers have asked for much faster Vim script. Investigations have shown that keeping the existing semantics of function calls make this close to impossible, because of the overhead involved with calling a function, setting up the local function scope and executing lines. There are many details that need to be handled, such as error messages and exceptions. The need to create a dictionary for a: and l: scopes, the a:000 list and several others add too much overhead that cannot be avoided.

Therefore the ``:def`` method to define a new-style function had to be added, which allows for a function with different semantics. Most things still work as before, but some parts do not. A new way to define a function was considered the best way to separate the legacy style code from Vim9 style code.

Using "def" to define a function comes from Python. Other languages use "function" which clashes with legacy Vim script.

### Type checking

When compiling lines of Vim commands into instructions as much as possible should be done at compile time. Postponing it to runtime makes the execution slower and means mistakes are found only later. For example, when encountering the "+" character and compiling this into a generic add instruction, at runtime the instruction would have to inspect the type of the arguments and decide what kind of addition to do. And when the type is dictionary throw an error. If the types are known to be numbers then an "add number" instruction can be used, which is faster. The error can be given at compile time, no error handling is needed at runtime, since adding two numbers cannot fail.

The syntax for types, using `<type>` for compound types, is similar to Java. It is easy to understand and widely used. The type names are what were used in Vim before, with some additions such as "void" and "bool".

### Removing clutter and weirdness

Once decided that ``:def`` functions have different syntax than legacy functions, we are free to add improvements to make the code more familiar for users who know popular programming languages. In other words: remove weird things that only Vim does.

We can also remove clutter, mainly things that were done to make Vim script backwards compatible with the good old Vi commands.

Examples:

- Drop ``:call`` for calling a function and ``:eval`` for evaluating an expression.
- Drop using a leading backslash for line continuation, automatically figure out where an expression ends.

However, this does require that some things need to change:

- Comments start with # instead of ", to avoid confusing them with strings.

This is good anyway, it is also used by several popular languages.

- Ex command ranges need to be prefixed with a colon, to avoid confusion with expressions (single quote can be a string or a mark, "/" can be divide or a search command, etc.).

Goal is to limit the differences. A good criteria is that when the old syntax is accidentally used you are very likely to get an error message.

## Syntax and semantics from popular languages

Script writers have complained that the Vim script syntax is unexpectedly different from what they are used to. To reduce this complaint popular languages are used as an example. At the same time, we do not want to abandon the well-known parts of legacy Vim script.

For many things TypeScript is followed. It's a recent language that is gaining popularity and has similarities with Vim script. It also has a mix of static typing (a variable always has a known value type) and dynamic typing (a variable can have different types, this changes at runtime). Since legacy Vim script is dynamically typed and a lot of existing functionality (esp. builtin functions) depends on that, while static typing allows for much faster execution, we need to have this mix in Vim9 script.

There is no intention to completely match TypeScript syntax and semantics. We just want to take those parts that we can use for Vim and we expect Vim users will be happy with. TypeScript is a complex language with its own history, advantages and disadvantages. To get an idea of the disadvantages read the book: "JavaScript: The Good Parts". Or find the article "TypeScript: the good parts" and read the "Things to avoid" section.

People familiar with other languages (Java, Python, etc.) will also find things in TypeScript that they do not like or do not understand. We'll try to avoid those things.

Specific items from TypeScript we avoid:

- Overloading "+", using it both for addition and string concatenation. This goes against legacy Vim script and often leads to mistakes. For that reason we will keep using ".." for string concatenation. Lua also uses ".." this way. And it allows for conversion to string for more values.
- TypeScript can use an expression like "99 || 'yes'" in a condition, but cannot assign the value to a boolean. That is inconsistent and can be annoying. Vim recognizes an expression with && or || and allows using the result as a bool. The `falsy-operator` was added for the mechanism to use a default value.
- TypeScript considers an empty string as Falsy, but an empty list or dict as Truthy. That is inconsistent. In Vim an empty list and dict are also Falsy.
- TypeScript has various "Readonly" types, which have limited usefulness, since a type cast can remove the immutable nature. Vim locks the value, which is more flexible, but is only checked at runtime.
- TypeScript has a complicated "import" statement that does not match how the Vim import mechanism works. A much simpler mechanism is used instead, which matches that the imported script is only sourced once.

## Declarations

Legacy Vim script uses `:let` for every assignment, while in Vim9 declarations are used. That is different, thus it's good to use a different command: `:var`. This is used in many languages. The semantics might be slightly different, but it's easily recognized as a declaration.

Using `:const` for constants is common, but the semantics varies. Some languages only make the variable immutable, others also make the value immutable. Since "final" is well known from Java for only making the variable immutable we decided to use that. And then `:const` can be used for making both immutable. This was also used in legacy Vim script and the meaning is almost the same.

What we end up with is very similar to Dart:

```
:var name # mutable variable and value
:final name # immutable variable, mutable value
:const name # immutable variable and value
```

Since legacy and Vim9 script will be mixed and global variables will be shared, optional type checking is desirable. Also, type inference will avoid the need for specifying the type in many cases. The TypeScript syntax fits best for adding types to declarations:

```
var name: string # string type is specified
...
name = 'John'
const greeting = 'hello' # string type is inferred
```

This is how we put types in a declaration:

```
var mylist: list<string>
final mylist: list<string> = ['foo']
def Func(arg1: number, arg2: string): bool
```

Two alternatives were considered:

1. Put the type before the name, like Dart:

```
var list<string> mylist
final list<string> mylist = ['foo']
def Func(number arg1, string arg2) bool
```

2. Put the type after the variable name, but do not use a colon, like Go:

```
var mylist list<string>
final mylist list<string> = ['foo']
def Func(arg1 number, arg2 string) bool
```

The first is more familiar for anyone used to C or Java. The second one doesn't really have an advantage over the first, so let's discard the second.

Since we use type inference the type can be left out when it can be inferred from the value. This means that after `var` we don't know if a type or a name follows. That makes parsing harder, not only for Vim but also for humans. Also, it will not be allowed to use a variable name that could be a type name, using `var string string` is too confusing.

The chosen syntax, using a colon to separate the name from the type, adds punctuation, but it actually makes it easier to recognize the parts of a declaration.

## Expressions

Expression evaluation was already close to what other languages are doing. Some details are unexpected and can be improved. For example a boolean condition would accept a string, convert it to a number and check if the number is non-zero. This is unexpected and often leads to mistakes, since text not starting with a number would be converted to zero, which is considered false. Thus using a string for a condition would often not give an error and be considered false. That is confusing.

In Vim9 type checking is stricter to avoid mistakes. Where a condition is used, e.g. with the `:if` command and the `||` operator, only boolean-like values are accepted:

```
true: `true`, `v:true`, `1`, `0 < 9`
false: `false`, `v:false`, `0`, `0 > 9`
```

**Note** that the number zero is false and the number one is true. This is more permissive than most other languages. It was done because many builtin functions return these values, and changing that causes more problems than it solves. After using this for a while it turned out to work well.

If you have any type of value and want to use it as a boolean, use the `!!` operator:

```
true: `!!'text'` `!![99]` `!!{'x': 1}` `!!99`
false: `!!''` `!![]` `!!{}`
```

From a language like JavaScript we have this handy construct:

```
GetName() || 'unknown'
```

However, this conflicts with only allowing a boolean for a condition.

Therefore the `??` operator was added:

```
GetName() ?? 'unknown'
```

Here you can explicitly express your intention to use the value as-is and not result in a boolean. This is called the [falsy-operator](#) .

## Import and Export

A problem of legacy Vim script is that by default all functions and variables are global. It is possible to make them script-local, but then they are not available in other scripts. This defies the concept of a package that only exports selected items and keeps the rest local.

In Vim9 script a mechanism very similar to the JavaScript import and export mechanism is supported. It is a variant to the existing `:source` command that works like one would expect:

- Instead of making everything global by default, everything is script-local, some of these are exported.
- When importing a script the symbols that are imported are explicitly listed, avoiding name conflicts and failures if functionality is added later.
- The mechanism allows for writing a big, long script with a very clear API:

the exported functions, variables and classes.

- By using relative paths loading can be much faster for an import inside of a package, no need to search many directories.
- Once an import has been used, its items are cached and loading it again is not needed.
- The Vim-specific use of "s:" to make things script-local can be dropped.

When sourcing a Vim9 script (from a Vim9 or legacy script), only the items defined globally can be used, not the exported items. Alternatives considered:

- All the exported items become available as script-local items. This makes it uncontrollable what items get defined and likely soon leads to trouble.
- Use the exported items and make them global. Disadvantage is that it's then not possible to avoid name clashes in the global namespace.
- Completely disallow sourcing a Vim9 script, require using `:import`. That makes it difficult to use scripts for testing, or sourcing them from the command line to try them out.

Note that you CAN also use `:import` in legacy Vim script, see above.

### Compiling functions early

Functions are compiled when called or when `:defcompile` is used. Why not compile them early, so that syntax and type errors are reported early?

The functions can't be compiled right away when encountered, because there may be forward references to functions defined later. Consider defining functions A, B and C, where A calls B, B calls C, and C calls A again. It's impossible to reorder the functions to avoid forward references.

An alternative would be to first scan through the file to locate items and figure out their type, so that forward references are found, and only then execute the script and compile the functions. This means the script has to be parsed twice, which is slower, and some conditions at the script level, such as checking if a feature is supported, are hard to use. An attempt was made to see if it works, but it turned out to be impossible to make work well.

It would be possible to compile all the functions at the end of the script. The drawback is that if a function never gets called, the overhead of compiling it counts anyway. Since startup speed is very important, in most cases it's better to do it later and accept that syntax and type errors are only reported then. In case these errors should be found early, e.g. when testing, a `:defcompile` command at the end of the script will help out.

### Why not use an existing embedded language?

Vim supports interfaces to Perl, Python, Lua, Tcl and a few others. But these interfaces have never become widely used, for various reasons. When Vim9 was designed a decision was made to make these interfaces lower priority and concentrate on Vim script.

Still, plugin writers may find other languages more familiar, want to use existing libraries or see a performance benefit. We encourage plugin authors

to write code in any language and run it as an external process, using jobs and channels. We can try to make this easier somehow.

Using an external tool also has disadvantages. An alternative is to convert the tool into Vim script. For that to be possible without too much translation, and keeping the code fast at the same time, the constructs of the tool need to be supported. Since most languages support classes the lack of support for classes in Vim is then a problem.

This file is about indenting C programs and other files.

1. Indenting C style programs [C-indenting](#)
2. Indenting by expression [indent-expression](#)

---

## 1. Indenting C style programs [C-indenting](#)

The basics for C style indenting are explained in section [30.2](#) of the user manual.

Vim has options for automatically indenting C style program files. Many programming languages including Java and C++ follow very closely the formatting conventions established with C. These options affect only the indent and do not perform other formatting. There are additional options that affect other kinds of formatting as well as indenting, see [format-comments](#), [fo-table](#), [gq](#) and [formatting](#) for the main ones.

There are in fact four main methods available for indentation, each one overrides the previous if it is enabled, or non-empty for **'indentexpr'**:

- 'autoindent'** uses the indent from the previous line.
- 'smartindent'** is like **'autoindent'** but also recognizes some C syntax to increase/reduce the indent where appropriate.
- 'cindent'** Works more cleverly than the other two and is configurable to different indenting styles.
- 'indentexpr'** The most flexible of all: Evaluates an expression to compute the indent of a line. When non-empty this method overrides the other ones. See [indent-expression](#).

The rest of this section describes the **'cindent'** option.

**Note** that **'cindent'** indenting does not work for every code scenario. Vim is not a C compiler: it does not recognize all syntax. One requirement is that toplevel functions have a '{' in the first column. Otherwise they are easily confused with declarations.

These five options control C program indenting:

- 'cindent'** Enables Vim to perform C program indenting automatically.
- 'cinkeys'** Specifies which keys trigger reindenting in insert mode.
- 'cinoptions'** Sets your preferred indent style.
- 'cinwords'** Defines keywords that start an extra indent in the next line.
- 'cinscopedecls'** Defines strings that are recognized as a C++ scope declaration.

If **'lisp'** is not on and **'equalprg'** is empty, the "=" operator indents using Vim's built-in algorithm rather than calling an external program.

See [autocommand](#) for how to set the **'cindent'** option automatically for C code files and reset it for others.

cinkeys-format    indentkeys-format

The '**cinkeys**' option is a string that controls Vim's indenting in response to typing certain characters or commands in certain contexts. **Note** that this not only triggers C-indenting. When '**indentexpr**' is not empty '**indentkeys**' is used instead. The format of '**cinkeys**' and '**indentkeys**' is equal.

The default is "0{,0},0),0],:,0#,!^F,o,0,e" which specifies that indenting occurs as follows:

"0{"	if you type '{' as the first character in a line
"0}"	if you type '}' as the first character in a line
"0)"	if you type ')' as the first character in a line
"0]"	if you type ']' as the first character in a line
":"	if you type ':' after a label or case statement
"0#"	if you type '#' as the first character in a line
"!^F"	if you type <b>CTRL-F</b> (which is not inserted)
"o"	if you type a <b>&lt;CR&gt;</b> anywhere or use the "o" command (not in insert mode!)
"O"	if you use the "O" command (not in insert mode!)
"e"	if you type the second 'e' for an "else" at the start of a line

Characters that can precede each key:

i\_CTRL-F

- ! When a '!' precedes the key, Vim will not insert the key but will instead reindent the current line. This allows you to define a command key for reindenting the current line. **CTRL-F** is the default key for this. Be careful if you define **CTRL-I** for this because **CTRL-I** is the ASCII code for **<Tab>**.
- \* When a '\*' precedes the key, Vim will reindent the line before inserting the key. If '**cinkeys**' contains "**\*<Return>**", Vim reindents the current line before opening a new line.
- 0 When a zero precedes the key (but appears after '!' or '\*') Vim will reindent the line only if the key is the first character you type in the line. When used before "=" Vim will only reindent the line if there is only white space before the word.

When neither '!' nor '\*' precedes the key, Vim reindents the line after you type the key. So ';' sets the indentation of a line which includes the ';'.

Special key names:

- <> Angle brackets mean spelled-out names of keys. For example: "**<Up>**", "**<Ins>**" (see [key-notation](#) ).
- ^ Letters preceded by a caret (^) are control characters. For example: "**^F**" is **CTRL-F**.
- o Reindent a line when you use the "o" command or when Vim opens a new line below the current one (e.g., when you type **<Enter>** in insert mode).
- O Reindent a line when you use the "O" command.
- e Reindent a line that starts with "else" when you type the second 'e'.
- :
- Reindent a line when a ':' is typed which is after a label or case statement. Don't reindent for a ":" in "class::method" for C++. To Reindent for any ":", use "**<:>**".
- =word Reindent when typing the last character of "word". "word" may actually be part of another word. Thus "=end" would cause reindenting

when typing the "d" in "endif" or "endwhile". But not when typing "bend". Also reindent when completion produces a word that starts with "word". "0=word" reindents when there is only white space before the word.

=~word Like =word, but ignore case.

If you really want to reindent when you type 'o', 'O', 'e', 'E', '<', '>', '\*', ':', '!' or '!', use "<o>", "<O>", "<e>", "<E>", "<<>", "<>>", "<\*>", "<:>" or "<!>", respectively, for those keys.

For an emacs-style indent mode where lines aren't indented every time you press <Enter> but only if you press <Tab>, I suggest:

```
:set cinkeys=0{,0},:,0#,!<Tab>,!^F
```

You might also want to switch off 'autoindent' then.

**Note:** If you change the current line's indentation manually, Vim ignores the cindent settings for that line. This prevents vim from reindenting after you have changed the indent by typing <BS>, <Tab>, or <Space> in the indent or used **CTRL-T** or **CTRL-D**.

#### cinoptions-values

The 'cinoptions' option sets how Vim performs indentation. The value after the option character can be one of these (N is any number):

```
N indent N spaces
-N indent N spaces to the left
Ns N times 'shiftwidth' spaces
-Ns N times 'shiftwidth' spaces to the left
```

In the list below,

"N" represents a number of your choice (the number can be negative). When there is an 's' after the number, Vim multiplies the number by 'shiftwidth': "1s" is 'shiftwidth', "2s" is two times 'shiftwidth', etc. You can use a decimal point, too: "-0.5s" is minus half a 'shiftwidth'.

The examples below assume a 'shiftwidth' of 4.

#### cin->

>N Amount added for "normal" indent. Used after a line that should increase the indent (lines starting with "if", an opening brace, etc.). (default 'shiftwidth').

```
cin= cin=>2 cin=>2s
 if (cond) if (cond) if (cond)
 { { {
 foo; foo; foo;
 } } }
```

#### cin-e

eN Add N to the prevailing indent inside a set of braces if the opening brace at the End of the line (more precise: is not the first character in a line). This is useful if you want a different indent when the '{' is at the start of the line from when '{' is at the end of the line. (default 0).

```
cin= cin=e2 cin=e-2
 if (cond) { if (cond) { if (cond) {
```

```

 foo;
 }
else
{
 bar;
}

```

```

 foo;
 }
else
{
 bar;
}

```

```

 foo;
 }
else
{
 bar;
}

```

cino-n

nN Add N to the prevailing indent for a statement after an "if", "while", etc., if it is NOT inside a set of braces. This is useful if you want a different indent when there is no '{' before the statement from when there is a '{' before it. (default 0).

```

cino=
 if (cond)
 foo;
 else
 {
 bar;
 }

```

```

cino=n2
 if (cond)
 foo;
 else
 {
 bar;
 }

```

```

cino=n-2
 if (cond)
 foo;
 else
 {
 bar;
 }

```

cino-f

fN Place the first opening brace of a function or other block in column N. This applies only for an opening brace that is not inside other braces and is at the start of the line. What comes after the brace is put relative to this brace. (default 0).

```

cino=
 func()
 {
 int foo;
 }

```

```

cino=f.5s
 func()
 {
 int foo;
 }

```

```

cino=f1s
 func()
 {
 int foo;
 }

```

cino-{

{N Place opening braces N characters from the prevailing indent. This applies only for opening braces that are inside other braces. (default 0).

```

cino=
 if (cond)
 {
 foo;
 }

```

```

cino={.5s
 if (cond)
 {
 foo;
 }

```

```

cino={1s
 if (cond)
 {
 foo;
 }

```

cino-}

}N Place closing braces N characters from the matching opening brace. (default 0).

```

cino=
 if (cond)
 {
 foo;
 }

```

```

cino={2,}-0.5s
 if (cond)
 {
 foo;
 }

```

```

cino=}2
 if (cond)
 {
 foo;
 }

```

cino-^

**^N** Add N to the prevailing indent inside a set of braces if the opening brace is in column 0. This can specify a different indent for whole of a function (some may like to set it to a negative number). (default 0).

<pre> cino= func() {     if (cond)     {         a = b;     } } </pre>	<pre> cino=^-2 func() {     if (cond)     {         a = b;     } } </pre>	<pre> cino=^-s func() {     if (cond)     {         a = b;     } } </pre>
------------------------------------------------------------------------	---------------------------------------------------------------------------	---------------------------------------------------------------------------

**LN** Controls placement of jump labels. If N is negative, the label will be placed at column 1. If N is non-negative, the indent of the label will be the prevailing indent minus N. (default -1).

<pre> cino= func() {     {         stmt;     LABEL:     } } </pre>	<pre> cino=L2 func() {     {         stmt;     LABEL:     } } </pre>	<pre> cino=Ls func() {     {         stmt;     LABEL:     } } </pre>
--------------------------------------------------------------------	----------------------------------------------------------------------	----------------------------------------------------------------------

**:N** Place case labels N characters from the indent of the switch(). (default 'shiftwidth').

<pre> cino= switch (x) {     case 1:         a = b;     default: } </pre>	<pre> cino=:0 switch(x) {     case 1:         a = b;     default: } </pre>
---------------------------------------------------------------------------	----------------------------------------------------------------------------

**=N** Place statements occurring after a case label N characters from the indent of the label. (default 'shiftwidth').

<pre> cino= case 11:     a = a + 1; </pre>	<pre> cino==10 case 11: a = a + 1;         b = b + 1; </pre>
--------------------------------------------	--------------------------------------------------------------

**lN** If N != 0 Vim will align with a case label instead of the statement after it in the same line.

<pre> cino= switch (a) { </pre>	<pre> cino=l1 switch (a) { </pre>
---------------------------------	-----------------------------------

```

 case 1: {
 break;
 }

```

cino-b

bN If N != 0 Vim will align a final "break" with the case label, so that case..break looks like a sort of block. (default: 0). When using 1, consider adding "0=break" to 'cinkeys'.

```

cino=
switch (x)
{
 case 1:
 a = b;
 break;

 default:
 a = 0;
 break;
}

cino=b1
switch(x)
{
 case 1:
 a = b;
 break;

 default:
 a = 0;
 break;
}

```

cino-g

gN Place C++ scope declarations N characters from the indent of the block they are in. (default 'shiftwidth'). By default, a scope declaration is "public:", "protected:" or "private:". This can be adjusted with the 'cinscopedecls' option.

```

cino=
{
 public:
 a = b;
 private:
}

cino=g0
{
 public:
 a = b;
 private:
}

```

cino-h

hN Place statements occurring after a C++ scope declaration N characters from the indent of the label. (default 'shiftwidth').

```

cino=
 public:
 a = a + 1;

cino=h10
 public: a = a + 1;
 b = b + 1;

```

cino-N

NN Indent inside C++ namespace N characters extra compared to a normal block. (default 0).

```

cino=
namespace {
 void function();
}

namespace my
{

cino=N-s
namespace {
 void function();
}

namespace my
{

```

```

 void function();
 }
 void function();
 }

```

cino-E

EN Indent inside C++ linkage specifications (extern "C" or extern "C++") N characters extra compared to a normal block. (default 0).

```

cino=
extern "C" {
 void function();
}

extern "C"
{
 void function();
}

cino=E-s
extern "C" {
 void function();
}

extern "C"
{
 void function();
}

```

cino-p

pN Parameter declarations for K&R-style function declarations will be indented N characters from the margin. (default 'shiftwidth').

```

cino=
func(a, b)
 int a;
 char b;

cino=p0
func(a, b)
 int a;
 char b;

cino=p2s
func(a, b)
 int a;
 char b;

```

cino-t

tN Indent a function return type declaration N characters from the margin. (default 'shiftwidth').

```

cino=
 int
func()

cino=t0
 int
func()

cino=t7
func() int

```

cino-i

iN Indent C++ base class declarations and constructor initializations, if they start in a new line (otherwise they are aligned at the right side of the ':'). (default 'shiftwidth').

```

cino=
class MyClass :
 public BaseClass
{}
MyClass::MyClass() :
 BaseClass(3)
{}

cino=i0
class MyClass :
 public BaseClass
{}
MyClass::MyClass() :
 BaseClass(3)
{}

```

cino-+

+N Indent a continuation line (a line that spills onto the next) inside a function N additional characters. (default 'shiftwidth').

Outside of a function, when the previous line ended in a backslash, the 2 \* N is used.

```

cino= cino=+10
 a = b + 9 * a = b + 9 *
 c; c;

```

**cino-c**

cN Indent comment lines after the comment opener, when there is no other text with which to align, N characters from the comment opener. (default 3). See also [format-comments](#) .

```

cino= cino=c5
 /* /*
 text. text.
 */ */

```

**cino-C**

CN When N is non-zero, indent comment lines by the amount specified with the c flag above even if there is other text behind the comment opener. (default 0).

```

cino=c0 cino=c0,C1
 /****** /******
 text. text.
 /******/ /******/

```

(Example uses ":set comments& comments--s1:/\* comments^=s0:/\*")

**cino-/**

/N Indent comment lines N characters extra. (default 0).

```

cino= cino=/4
 a = b; a = b;
 /* comment */ /* comment */
 c = d; c = d;

```

**cino-(**

(N When in unclosed parentheses, indent N characters from the line with the unclosed parenthesis. Add a **'shiftwidth'** for every extra unclosed parentheses. When N is 0 or the unclosed parenthesis is the first non-white character in its line, line up with the next non-white character after the unclosed parenthesis. (default **'shiftwidth'** \* 2).

```

cino= cino=(0
 if (c1 && (c2 || if (c1 && (c2 ||
 c3)) c3))
 foo; foo;
 if (c1 && if (c1 &&
 (c2 || c3)) (c2 || c3))
 { {

```

**cino-u**

uN Same as (N, but for one nesting level deeper. (default **'shiftwidth'**).

<pre> cino=   if (c123456789       &amp;&amp; (c22345              c3)) </pre>	<pre> cino=u2   if (c123456789       &amp;&amp; (c22345              c3)) </pre>
--------------------------------------------------------------------------------	----------------------------------------------------------------------------------

cino-U

UN When N is non-zero, do not ignore the indenting specified by ( or u in case that the unclosed parenthesis is the first non-white character in its line. (default 0).

<pre> cino= or cino=(s   c = c1 &amp;&amp;   (     c2        c3   ) &amp;&amp; c4; </pre>	<pre> cino=(s,U1   c = c1 &amp;&amp;   (     c2        c3   ) &amp;&amp; c4; </pre>
-------------------------------------------------------------------------------------------	-------------------------------------------------------------------------------------

cino-w

WN When in unclosed parentheses and N is non-zero and either using "(0" or "u0", respectively, or using "U0" and the unclosed parenthesis is the first non-white character in its line, line up with the character immediately after the unclosed parenthesis rather than the first non-white character. (default 0).

<pre> cino=(0   if ( c1       &amp;&amp; ( c2              c3))   foo; </pre>	<pre> cino=(0,w1   if ( c1       &amp;&amp; ( c2              c3))   foo; </pre>
-------------------------------------------------------------------------------	----------------------------------------------------------------------------------

cino-W

WN When in unclosed parentheses and N is non-zero and either using "(0" or "u0", respectively and the unclosed parenthesis is the last non-white character in its line and it is not the closing parenthesis, indent the following line N characters relative to the outer context (i.e. start of the line or the next unclosed parenthesis). (default: 0).

<pre> cino=(0   a_long_line(     argument,     argument);   a_short_line(argument,     argument); </pre>	<pre> cino=(0,W4   a_long_line(     argument,     argument);   a_short_line(argument,     argument); </pre>
----------------------------------------------------------------------------------------------------------	-------------------------------------------------------------------------------------------------------------

cino-k

kN When in unclosed parentheses which follow "if", "for" or "while" and N is non-zero, overrides the behaviour defined by "(N": causes the indent to be N characters relative to the outer context (i.e. the line where "if", "for" or "while" is). Has no effect on deeper levels of nesting. Affects flags like "wN" only for the "if", "for" and "while" conditions. If 0, defaults to behaviour defined by the "(N" flag. (default: 0).

```

cino=(0
 if (condition1
 && condition2)
 action();
 function(argument1
 && argument2);

cino=(0,ks
 if (condition1
 && condition2)
 action();
 function(argument1
 && argument2);

```

[cino-m](#)

mN When N is non-zero, line up a line starting with a closing parenthesis with the first character of the line with the matching opening parenthesis. (default 0).

```

cino=(s
 c = c1 && (
 c2 ||
 c3
) && c4;
 if (
 c1 && c2
)
 foo;

cino=(s,m1
 c = c1 && (
 c2 ||
 c3
) && c4;
 if (
 c1 && c2
)
 foo;

```

[cino-M](#)

MN When N is non-zero, line up a line starting with a closing parenthesis with the first character of the previous line. (default 0).

```

cino=
 if (cond1 &&
 cond2
)

cino=M1
 if (cond1 &&
 cond2
)

```

[java-cinoptions](#) [java-indenting](#) [cino-j](#)

jN Indent Java anonymous classes correctly. Also works well for Javascript. The value 'N' is currently unused but must be non-zero (e.g. 'j1'). 'j1' will indent for example the following code snippet correctly:

```

object.add(new ChangeListener() {
 public void stateChanged(ChangeEvent e) {
 do_something();
 }
});

```

[javascript-cinoptions](#) [javascript-indenting](#) [cino-J](#)

JN Indent JavaScript object declarations correctly by not confusing them with labels. The value 'N' is currently unused but must be non-zero (e.g. 'J1'). If you enable this you probably also want to set [cino-j](#) .

```

var bar = {
 foo: {
 that: this,

```

```

 some: ok,
 },
 "bar":{
 a : 2,
 b: "123abc",
 x: 4,
 "y": 5
 }
}

```

- cino-)
- )N Vim searches for unclosed parentheses at most N lines away. This limits the time needed to search for parentheses. (default 20 lines).
- cino-star
- \*N Vim searches for unclosed comments at most N lines away. This limits the time needed to search for the start of a comment. If your /\* \*/ comments stop indenting after N lines this is the value you will want to change. (default 70 lines).
- cino-#
- #N When N is non-zero recognize shell/Perl comments starting with '#', do not recognize preprocessor lines; allow right-shifting lines that start with "#". When N is zero (default): don't recognize '#' comments, do recognize preprocessor lines; right-shifting lines that start with "#" does not work.
- cino-P
- PN When N is non-zero recognize C pragmas, and indent them like any other code; does not concern other preprocessor directives. When N is zero (default): don't recognize C pragmas, treating them like every other preprocessor directive.

The defaults, spelled out in full, are:

```

cinoptions=>s,e0,n0,f0,{0},0,^0,L-1,:s,=s,l0,b0,gs,hs,N0,E0,ps,ts,is,+s,
c3,C0,/0,(2s,us,U0,w0,W0,k0,m0,j0,J0,)20,*70,#0,P0

```

Vim puts a line in column 1 if:

- It starts with '#' (preprocessor directives), if **'cinkeys'** contains '#0'.
- It starts with a label (a keyword followed by ':', other than "case" and "default") and **'cinoptions'** does not contain an 'L' entry with a positive value.
- Any combination of indentations causes the line to have less than 0 indentation.

## 2. Indenting by expression

indent-expression

The basics for using flexible indenting are explained in section 30.3 of the user manual.

If you want to write your own indent file, it must set the `'indentexpr'` option. Setting the `'indentkeys'` option is often useful. See the `$VIMRUNTIME/indent/README.txt` file for hints. See the `$VIMRUNTIME/indent` directory for examples.

## REMARKS ABOUT SPECIFIC INDENT FILES

### CLOJURE

`ft-clojure-indent`    `clojure-indent`

Clojure indentation differs somewhat from traditional Lisps, due in part to the use of square and curly brackets, and otherwise by community convention. These conventions are not universally followed, so the Clojure indent script offers a few configuration options.

(If the current Vim does not include `searchpairpos()`, the indent script falls back to normal `'lisp'` indenting, and the following options are ignored.)

`g:clojure_maxlines`

Sets maximum scan distance of ``searchpairpos()`. Larger values trade performance for correctness when dealing with very long forms. A value of 0 will scan without limits. The default is 300.

`g:clojure_fuzzy_indent`  
`g:clojure_fuzzy_indent_patterns`  
`g:clojure_fuzzy_indent_blacklist`

The `'lispwords'` option is a list of comma-separated words that mark special forms whose subforms should be indented with two spaces.

For example:

```
(defn bad []
 "Incorrect indentation")

(defn good []
 "Correct indentation")
```

If you would like to specify `'lispwords'` with a `pattern` instead, you can use the fuzzy indent feature:

```
" Default
let g:clojure_fuzzy_indent = 1
let g:clojure_fuzzy_indent_patterns = ['^with', '^def', '^let']
let g:clojure_fuzzy_indent_blacklist =
 \ ['-fn$', '\v^with-(meta|out-str|loading-context)$']
```

`g:clojure_fuzzy_indent_patterns` and `g:clojure_fuzzy_indent_blacklist` are lists of patterns that will be matched against the unqualified symbol at the

head of a list. This means that a pattern like `"^foo"` will match all these candidates: `'foobar'`, `'my.ns/foobar'`, and `'#'foobar'`.

Each candidate word is tested for special treatment in this order:

1. Return true if word is literally in `'lispwords'`
2. Return false if word matches a pattern in `g:clojure_fuzzy_indent_blacklist`
3. Return true if word matches a pattern in `g:clojure_fuzzy_indent_patterns`
4. Return false and indent normally otherwise

`g:clojure_special_indent_words`

Some forms in Clojure are indented such that every subform is indented by only two spaces, regardless of `'lispwords'`. If you have a custom construct that should be indented in this idiosyncratic fashion, you can add your symbols to the default list below.

```
" Default
let g:clojure_special_indent_words =
 \ 'deftype,defrecord,reify,proxy,extend-type,extend-protocol,letfn'
```

`g:clojure_align_multiline_strings`

Align subsequent lines in multi-line strings to the column after the opening quote, instead of the same column.

For example:

```
(def default
 "Lorem ipsum dolor sit amet, consectetur adipisicing elit, sed do
 eiusmod tempor incididunt ut labore et dolore magna aliqua. Ut
 enim ad minim veniam, quis nostrud exercitation ullamco laboris
 nisi ut aliquip ex ea commodo consequat.")

(def aligned
 "Lorem ipsum dolor sit amet, consectetur adipisicing elit, sed do
 eiusmod tempor incididunt ut labore et dolore magna aliqua. Ut
 enim ad minim veniam, quis nostrud exercitation ullamco laboris
 nisi ut aliquip ex ea commodo consequat.")
```

`g:clojure_align_subforms`

By default, parenthesized compound forms that look like function calls and whose head subform is on its own line have subsequent subforms indented by two spaces relative to the opening paren:

```
(foo
 bar
 baz)
```

Setting this option to `1` changes this behaviour so that all subforms are aligned to the same column, emulating the default behaviour of `clojure-mode.el`:

```
(foo
 bar
 baz)
```

## **FORTRAN**

## **ft-fortran-indent**

Block `if`, `select case`, `select type`, `select rank`, `where`, `forall`, `type`, `interface`, `associate`, `block`, `enum`, `critical`, and `change team` constructs are indented. The indenting of subroutines, functions, modules, and program blocks is optional. Comments, labeled statements, and continuation lines are indented if the Fortran is in free source form, whereas they are not indented if the Fortran is in fixed source form because of the left margin requirements. Hence manual indent corrections will be necessary for labeled statements and continuation lines when fixed source form is being used. For further discussion of the method used for the detection of source format see [ft-fortran-syntax](#) .

### **Do loops**

All do loops are left unindented by default. Do loops can be unstructured in Fortran with (possibly multiple) loops ending on a labeled executable statement of almost arbitrary type. Correct indentation requires compiler-quality parsing. Old code with do loops ending on labeled statements of arbitrary type can be indented with elaborate programs such as Tidy. Structured do/continue loops are also left unindented because continue statements are used for purposes other than ending a do loop. Programs such as Tidy can convert structured do/continue loops to the do/enddo form. Do loops of the do/enddo variety can be indented. If you use only structured loops of the do/enddo form, you should declare this by setting the `fortran_do_enddo` variable in your `.vimrc` as follows

```
let fortran_do_enddo=1
```

in which case do loops will be indented. If all your loops are of do/enddo type only in, say, `.f90` files, then you should set a buffer flag with an autocommand such as

```
au! BufRead,BufNewFile *.f90 let b:fortran_do_enddo=1
```

to get do loops indented in `.f90` files and left alone in Fortran files with other extensions such as `.for`.

### **Program units**

Indenting of program units (subroutines, functions, modules, and program blocks) can be increased by setting the variable `fortran_indent_more` and can be decreased by setting the variable `fortran_indent_less`. These variables can be set for all fortran files in your `.vimrc` as follows

```
let fortran_indent_less=1
```

A finer level of control can be achieved by setting the corresponding buffer-local variable as follows

```
let b:fortran_indent_less=1
```

**HTML** `ft-html-indent` `html-indent` `html-indenting`

This is about variables you can set in your vimrc to customize HTML indenting.

You can set the indent for the first line after `<script>` and `<style>` "blocktags" (default "zero"):

```
:let g:html_indent_script1 = "inc"
:let g:html_indent_style1 = "inc"
```

VALUE	MEANING
"zero"	zero indent
"auto"	auto indent (same indent as the blocktag)
"inc"	auto indent + one indent step

You can set the indent for attributes after an open `<tag` line:

```
:let g:html_indent_attribute = 1
```

VALUE	MEANING
1	auto indent, one indent step more than <code>&lt;tag</code>
2	auto indent, two indent steps (default)
> 2	auto indent, more indent steps

Many tags increase the indent for what follows per default (see "Add Indent Tags" in the script). You can add further tags with:

```
:let g:html_indent_inctags = "html,body,head,tbody"
```

You can also remove such tags with:

```
:let g:html_indent_autotags = "th,td,tr,tfoot,thead"
```

Default value is empty for both variables. **Note:** the initial "inctags" are only defined once per Vim session.

User variables are only read when the script is sourced. To enable your changes during a session, without reloading the HTML file, you can manually do:

```
:call HtmlIndent_CheckUserSettings()
```

Detail:

Calculation of indent inside "blocktags" with "alien" content:

BLOCKTAG	INDENT	EXPR	WHEN APPLICABLE
<code>&lt;script&gt;</code>	:	{customizable}	if first line of block
	:	cindent(v:lnum)	if attributes empty or contain "java"

```

: -1 else (vbscript, tcl, ...)
<style> : {customizable} if first line of block
: GetCSSIndent() else
<!-- --> : -1

```

## IDRIS2

[ft-idris2-indent](#)

Idris 2 indentation can be configured with several variables that control the indentation level for different language constructs:

The "g:idris2\_indent\_if" variable controls the indentation of ``then`` and ``else`` blocks after ``if`` statements. Defaults to 3.

The "g:idris2\_indent\_case" variable controls the indentation of patterns in ``case`` expressions. Defaults to 5.

The "g:idris2\_indent\_let" variable controls the indentation after ``let`` bindings. Defaults to 4.

The "g:idris2\_indent\_rewrite" variable controls the indentation after ``rewrite`` expressions. Defaults to 8.

The "g:idris2\_indent\_where" variable controls the indentation of ``where`` blocks. Defaults to 6.

The "g:idris2\_indent\_do" variable controls the indentation in ``do`` blocks. Defaults to 3.

Example configuration:

```

let g:idris2_indent_if = 2
let g:idris2_indent_case = 4
let g:idris2_indent_let = 4
let g:idris2_indent_rewrite = 8
let g:idris2_indent_where = 6
let g:idris2_indent_do = 3

```

## MATLAB

[ft-matlab-indent](#)   [matlab-indent](#)   [matlab-indenting](#)

The setting Function indenting format in MATLAB Editor/Debugger Language Preferences corresponds to:

```
:let g:MATLAB_function_indent = {0, 1 or 2 (default)}
```

Where 0 is for Classic, 1 for Indent nested functions and 2 for Indent all functions.

## PHP

[ft-php-indent](#)   [php-indent](#)   [php-indenting](#)

**NOTE:** PHP files will be indented correctly only if PHP [syntax](#) is active.

If you are editing a file in Unix `'fileformat'` and `'\r'` characters are present before new lines, indentation won't proceed correctly ; you have to remove

those useless characters first with a command like:

```
:%s /\r$/g
```

Or, you can simply `:let` the variable `PHP_removeCRwhenUnix` to 1 and the script will silently remove them when Vim loads a PHP file (at each `BufRead` ).

#### OPTIONS:

PHP indenting can be altered in several ways by modifying the values of some global variables:

To not enable auto-formatting of comments by default (if you want to use your own `'formatoptions'`):

```
php-comment PHP_autoformatcomment
:let g:PHP_autoformatcomment = 0
```

Else, 't' will be removed from the `'formatoptions'` string and "growcb" will be added, see `fo-table` for more information.

To add extra indentation to single-line comments:

```
PHP_outdentSLComments
:let g:PHP_outdentSLComments = N
```

With N being the number of `'shiftwidth'` to add.

Only single-line comments will be affected such as:

```
Comment
// Comment
/* Comment */
```

To add extra indentation to every PHP lines with N being the number of `'shiftwidth'` to add:

```
PHP_default_indentिंग
:let g:PHP_default_indentिंग = N
```

For example, with N = 1, this will give:

```
<?php
 if (!isset($History_lst_sel))
 if (!isset($History_lst_sel))
 if (!isset($History_lst_sel)) {
 $History_lst_sel=0;
 } else
 $foo="bar";

 $command_hist = TRUE;
?>
```

(Notice the extra indentation between the PHP container markers and the code)

PHP\_outdentphpescape

To indent PHP escape tags as the surrounding non-PHP code (only affects the PHP escape tags):

```
:let g:PHP_outdentphpescape = 0
```

---

*\*PHP\_removeCRwhenUnix\**

To automatically remove '\r' characters when the 'fileformat' is set to Unix:

```
:let g:PHP_removeCRwhenUnix = 1
```

---

*\*PHP\_BracesAtCodeLevel\**

To indent braces at the same level than the code they contain:

```
:let g:PHP_BracesAtCodeLevel = 1
```

This will give the following result:

```
if ($foo)
 {
 foo();
 }
```

Instead of:

```
if ($foo)
{
 foo();
}
```

**NOTE:** Indenting will be a bit slower if this option is used because some optimizations won't be available.

---

*PHP\_vintage\_case\_default\_indent*

To indent 'case:' and 'default:' statements in switch() blocks:

```
:let g:PHP_vintage_case_default_indent = 1
```

In PHP braces are not required inside 'case/default' blocks therefore 'case:' and 'default:' are indented at the same level than the 'switch()' to avoid meaningless indentation. You can use the above option to return to the traditional way.

---

*PHP\_noArrowMatching*

By default the indent script will indent multi-line chained calls by matching the position of the '->':

```
$user_name_very_long->name()
 ->age()
 ->info();
```

You can revert to the classic way of indenting by setting this option to 1:

```
:let g:PHP_noArrowMatching = 1
```

You will obtain the following result:

```
$user_name_very_long->name()
->age()
```

```
->info();
```

-----

\*PHP\_IndentFunctionCallParameters\*

Extra indentation levels to add to parameters in multi-line function calls.

```
let g:PHP_IndentFunctionCallParameters = 1
```

Function call arguments will indent 1 extra level. For two-space indentation:

```
function call_the_thing(
 $with_this,
 $and_that
) {
 $this->do_the_thing(
 $with_this,
 $and_that
);
}
```

-----

\*PHP\_IndentFunctionDeclarationParameters\*

Extra indentation levels to add to arguments in multi-line function definitions.

```
let g:PHP_IndentFunctionDeclarationParameters = 1
```

Function arguments in declarations will indent 1 extra level. For two-space indentation:

```
function call_the_thing(
 $with_this,
 $and_that
) {
 $this->do_the_thing(
 $with_this,
 $and_that
);
}
```

## PYTHON

ft-python-indent

The amount of indent can be set with the `g:python_indent` Dictionary, which needs to be created before adding the items:

```
let g:python_indent = {}
```

The examples given are the defaults. Note that the dictionary values are set to an expression, so that you can change the value of `'shiftwidth'` later without having to update these values.

Indent after an open paren:

```
let g:python_indent.open_paren = 'shiftwidth() * 2'
```

Indent after a nested paren:

```
let g:python_indent.nested_paren = 'shiftwidth()'
```

Indent for a continuation line:

```
let g:python_indent.continue = 'shiftwidth() * 2'
```

By default, the closing paren on a multiline construct lines up under the first non-whitespace character of the previous line.

If you prefer that it's lined up under the first character of the line that starts the multiline construct, reset this key:

```
let g:python_indent.closed_paren_align_last_line = v:false
```

The method uses `searchpair()` to look back for unclosed parentheses. This can sometimes be slow, thus it timeouts after 150 msec. If you notice the indenting isn't correct, you can set a larger timeout in msec:

```
let g:python_indent.searchpair_timeout = 500
```

If looking back for unclosed parenthesis is still too slow, especially during a copy-paste operation, or if you don't need indenting inside multi-line parentheses, you can completely disable this feature:

```
let g:python_indent.disable_parentheses_indenting = 1
```

For backward compatibility, these variables are also supported:

```
g:pyindent_open_paren
g:pyindent_nested_paren
g:pyindent_continue
g:pyindent_searchpair_timeout
g:pyindent_disable_parentheses_indenting
```

## R

`ft-r-indent`

Function arguments are aligned if they span for multiple lines. If you prefer do not have the arguments of functions aligned, put in your `vimrc` :

```
let r_indent_align_args = 0
```

All lines beginning with a comment character, #, get the same indentation level of the normal R code. Users of Emacs/ESS may be used to have lines beginning with a single # indented in the 40th column, ## indented as R code, and ### not indented. If you prefer that lines beginning with comment characters are aligned as they are by Emacs/ESS, put in your `vimrc` :

```
let r_indent_ess_comments = 1
```

If you prefer that lines beginning with a single # are aligned at a column different from the 40th one, you should set a new value to the variable `r_indent_comment_column`, as in the example below:

```
let r_indent_comment_column = 30
```

Any code after a line that ends with "`<-`" is indented. Emacs/ESS does not indent the code if it is a top-level function. If you prefer a behavior like Emacs/ESS one in this regard, put in your `vimrc` :

```
let r_indent_ess_compatible = 1
```

Below is an example of indentation with and without this option enabled:

```
r_indent_ess_compatible = 1 ### r_indent_ess_compatible = 0
foo <- foo <-
 function(x) function(x)
{ {
 paste(x) paste(x)
}
```

The code will be indented after lines that match the pattern ``\(&|\||\|+|\-|\*|\|/\|=|\|~|\%|\->)\s*$``. If you want indentation after lines that match a different pattern, you should set the appropriate value of ``r_indent_op_pattern`` in your `vimrc`.

## SHELL

## ft-sh-indent

The amount of indent applied under various circumstances in a shell file can be configured by setting the following keys in the [Dictionary](#) `b:sh_indent_defaults` to a specific amount or to a [Funcref](#) that references a function that will return the amount desired:

`b:sh_indent_options['default']` Default amount of indent.

`b:sh_indent_options['continuation-line']`  
Amount of indent to add to a continued line.

`b:sh_indent_options['case-labels']`  
Amount of indent to add for case labels.  
(not actually implemented)

`b:sh_indent_options['case-statements']`  
Amount of indent to add for case statements.

`b:sh_indent_options['case-breaks']`  
Amount of indent to add (or more likely remove) for case breaks.

## VERILOG

## ft-verilog-indent

General block statements such as `if`, `for`, `case`, `always`, `initial`, `function`, `specify` and `begin`, etc., are indented. The module block statements (first level blocks) are not indented by default. you can turn on the indent with setting a variable in the `.vimrc` as follows:

```
let b:verilog_indent_modules = 1
```

then the module blocks will be indented. To stop this, remove the variable:

```
:unlet b:verilog_indent_modules
```

To set the variable only for Verilog file. The following statements can be used:

```

au BufReadPost * if exists("b:current_syntax")
au BufReadPost * if b:current_syntax == "verilog"
au BufReadPost * let b:verilog_indent_modules = 1
au BufReadPost * endif
au BufReadPost * endif

```

Furthermore, setting the variable `b:verilog_indent_width` to change the indenting width (default is `'shiftwidth'`):

```

let b:verilog_indent_width = 4
let b:verilog_indent_width = shiftwidth() * 2

```

In addition, you can turn the verbose mode for debug issue:

```

let b:verilog_indent_verbose = 1

```

Make sure to do `":set cmdheight=2"` first to allow the display of the message.

## VHDL

`ft-vhdl-indent`

Alignment of generic/port mapping statements are performed by default. This causes the following alignment example:

```

ENTITY sync IS
PORT (
 clk : IN STD_LOGIC;
 reset_n : IN STD_LOGIC;
 data_input : IN STD_LOGIC;
 data_out : OUT STD_LOGIC
);
END ENTITY sync;

```

To turn this off, add

```

let g:vhdl_indent_genportmap = 0

```

to the `.vimrc` file, which causes the previous alignment example to change:

```

ENTITY sync IS
PORT (
 clk : IN STD_LOGIC;
 reset_n : IN STD_LOGIC;
 data_input : IN STD_LOGIC;
 data_out : OUT STD_LOGIC
);
END ENTITY sync;

```

---

Alignment of right-hand side assignment `"<="` statements are performed by default. This causes the following alignment example:

```

sig_out <= (bus_a(1) AND

```

```
(sig_b OR sig_c) OR
(bus_a(0) AND sig_d);
```

To turn this off, add

```
let g:vhdl_indent_rhsassign = 0
```

to the .vimrc file, which causes the previous alignment example to change:

```
sig_out <= (bus_a(1) AND
(sig_b OR sig_c) OR
(bus_a(0) AND sig_d);
```

---

Full-line comments (lines that begin with "--") are indented to be aligned with the very previous line's comment, PROVIDED that a whitespace follows after "--".

For example:

```
sig_a <= sig_b; -- start of a comment
 -- continuation of the comment
 -- more of the same comment
```

While in Insert mode, after typing "-- " (note the space " "), hitting **CTRL-F** will align the current "-- " with the previous line's "--".

If the very previous line does not contain "--", THEN the full-line comment will be aligned with the start of the next non-blank line that is NOT a full-line comment.

Indenting the following code:

```
sig_c <= sig_d; -- comment 0
 -- comment 1
 -- comment 2
--debug_code:
--PROCESS(debug_in)
--BEGIN
-- FOR i IN 15 DOWNTO 0 LOOP
-- debug_out(8*i+7 DOWNTO 8*i) <= debug_in(15-i);
-- END LOOP;
--END PROCESS debug_code;

-- comment 3
sig_e <= sig_f; -- comment 4
 -- comment 5
```

results in:

```
sig_c <= sig_d; -- comment 0
 -- comment 1
 -- comment 2
```

```

--debug_code:
--PROCESS(debug_in)
--BEGIN
-- FOR i IN 15 DOWNT0 0 LOOP
-- debug_out(8*i+7 DOWNT0 8*i) <= debug_in(15-i);
-- END LOOP;
--END PROCESS debug_code;

-- comment 3
sig_e <= sig_f; -- comment 4
 -- comment 5

```

Notice that "--debug\_code:" does not align with "-- comment 2" because there is no whitespace that follows after "--" in "--debug\_code:".

Given the dynamic nature of indenting comments, indenting should be done TWICE. On the first pass, code will be indented. On the second pass, full-line comments will be indented according to the correctly indented code.

## VIM

ft-vim-indent  
g:vim\_indent

Vim scripts indentation can be configured with the `g:vim_indent` dictionary variable. It supports 3 keys, `line_continuation`, `more_in_bracket_block`, and `searchpair_timeout`.

`line_continuation` expects a number which will be added to the indent level of a continuation line starting with a backslash, and defaults to `shiftwidth() * 3`. It also accepts a string, which is evaluated at runtime. `more_in_bracket_block` expects a boolean value; when on, an extra `shiftwidth()` is added inside blocks surrounded with brackets. It defaults to `v:false`.

`searchpair_timeout` expects a number which will be passed to `searchpair()` as a timeout. Increasing the value might give more accurate results, but also causes the indentation to take more time. It defaults to 100 (milliseconds).

Example of configuration:

```

let g:vim_indent = #{
 \ line_continuation: shiftwidth() * 3,
 \ more_in_bracket_block: v:false,
 \ searchpair_timeout: 100,
 \ }

```

g:vim\_indent\_cont

This variable is equivalent to `g:vim_indent.line_continuation`. It's supported for backward compatibility.

## YAML

ft-yaml-indent

By default, the yaml indent script does not try to detect multiline scalars. If you want to enable this, set the following variable:

```

let g:yaml_indent_multiline_scalar = 1

```

Syntax highlighting `syntax` `syntax-highlighting` `coloring`

Syntax highlighting enables Vim to show parts of the text in another font or color. Those parts can be specific keywords or text matching a pattern. Vim doesn't parse the whole file (to keep it fast), so the highlighting has its limitations. Lexical highlighting might be a better name, but since everybody calls it syntax highlighting we'll stick with that.

Vim supports syntax highlighting on all terminals. But since most ordinary terminals have very limited highlighting possibilities, it works best in the GUI version, gvim.

In the User Manual:

`usr_06.txt` introduces syntax highlighting.  
`usr_44.txt` introduces writing a syntax file.

- |                                   |                                |
|-----------------------------------|--------------------------------|
| 1. Quick start                    | <code>:syn-qstart</code>       |
| 2. Syntax files                   | <code>:syn-files</code>        |

| 5. Syntax file remarks            | <code>:syn-file-remarks</code> |
| 6. Defining a syntax              | <code>:syn-define</code>       |
| 7. <code>:syntax</code> arguments | <code>:syn-arguments</code>    |
| 8. Syntax patterns                | <code>:syn-pattern</code>      |
| 9. Syntax clusters                | <code>:syn-cluster</code>      |
| 10. Including syntax files        | <code>:syn-include</code>      |
| 11. Synchronizing                 | <code>:syn-sync</code>         |
| 12. Listing syntax items          | <code>:syntax</code>           |
| 13. Colorschemes                  | <code>color-schemes</code>     |
| 14. Highlight command             | <code>:highlight</code>        |
| 15. Linking groups                | <code>:highlight-link</code>   |
| 16. Cleaning up                   | <code>:syn-clear</code>        |
| 17. Highlighting tags             | <code>tag-highlight</code>     |
| 18. Window-local syntax           | <code>:ownsyntax</code>        |
| 19. Color xterms                  | <code>xterm-color</code>       |
| 20. When syntax is slow           | <code>:syntime</code>          |

{Vi does not have any of these commands}

Syntax highlighting is not available when the `+syntax` feature has been disabled at compile time.

```
=====
1. Quick start :syn-qstart
```

`:syn-enable` `:syntax-enable`

This command switches on syntax highlighting:

```
:syntax enable
```

What this command actually does is to execute the command

```
:source $VIMRUNTIME/syntax/syntax.vim
```

If the VIM environment variable is not set, Vim will try to find the path in another way (see `$VIMRUNTIME`). Usually this works just fine. If it doesn't, try setting the VIM environment variable to the directory where the Vim stuff is located. For example, if your syntax files are in the `"/usr/vim/vim82/syntax"` directory, set `$VIMRUNTIME` to `"/usr/vim/vim82"`. You must do this in the shell, before starting Vim. This command also sources the `menu.vim` script when the GUI is running or will start soon. See `'go-M'` about avoiding that.

```
:syn-on :syntax-on
```

The ``:syntax enable`` command will keep most of your current color settings. This allows using ``:highlight`` commands to set your preferred colors before or after using this command. If you want Vim to overrule your settings with the defaults, use:

```
:syntax on
```

```
:hi-normal :highlight-normal
```

If you are running in the GUI, you can get white text on a black background with:

```
:highlight Normal guibg=Black guifg=White
```

For a color terminal see `:hi-normal-cterm`.

For setting up your own colors syntax highlighting see `syncolor`.

**NOTE:** The syntax files on MS-Windows have lines that end in `<CR><NL>`. The files for Unix end in `<NL>`. This means you should use the right type of file for your system. Although on MS-Windows the right format is automatically selected if the `'fileformats'` option is not empty.

**NOTE:** When using reverse video (`"gvim -fg white -bg black"`), the default value of `'background'` will not be set until the GUI window is opened, which is after reading the `gvimrc`. This will cause the wrong default highlighting to be used. To set the default value of `'background'` before switching on highlighting, include the `":gui"` command in the `gvimrc`:

```
:gui " open window and set default for 'background'
:syntax on " start highlighting, use 'background' to set colors
```

**NOTE:** Using `":gui"` in the `gvimrc` means that `"gvim -f"` won't start in the foreground! Use `":gui -f"` then.

```
g:syntax_on
```

You can toggle the syntax on/off with this command:

```
:if exists("g:syntax_on") | syntax off | else | syntax enable | endif
```

To put this into a mapping, you can use:

```
:map <F7> :if exists("g:syntax_on") <Bar>
 \ syntax off <Bar>
 \ else <Bar>
 \ syntax enable <Bar>
```

```
\ endif <CR>
```

[using the <> notation, type this literally]

Details:

The ":syntax" commands are implemented by sourcing a file. To see exactly how this works, look in the file:

command	file
:syntax enable	\$VIMRUNTIME/syntax/syntax.vim
:syntax on	\$VIMRUNTIME/syntax/syntax.vim
:syntax manual	\$VIMRUNTIME/syntax/manual.vim
:syntax off	\$VIMRUNTIME/syntax/nosyntax.vim

Also see [syntax-loading](#) .

**NOTE:** If displaying long lines is slow and switching off syntax highlighting makes it fast, consider setting the '[synmaxcol](#)' option to a lower value.

---

## 2. Syntax files

[:syn-files](#)

The syntax and highlighting commands for one language are normally stored in a syntax file. The name convention is: "{name}.vim". Where {name} is the name of the language, or an abbreviation (to fit the name in 8.3 characters, a requirement in case the file is used on a DOS filesystem).

Examples:

c.vim	perl.vim	java.vim	html.vim
cpp.vim	sh.vim	csh.vim	

The syntax file can contain any Ex commands, just like a vimrc file. But the idea is that only commands for a specific language are included. When a language is a superset of another language, it may include the other one, for example, the cpp.vim file could include the c.vim file:

```
:so $VIMRUNTIME/syntax/c.vim
```

The .vim files are normally loaded with an autocommand. For example:

```
:au Syntax c runtime! syntax/c.vim
:au Syntax cpp runtime! syntax/cpp.vim
```

These commands are normally in the file \$VIMRUNTIME/syntax/synload.vim.

## MAKING YOUR OWN SYNTAX FILES

[mysyntaxfile](#)

When you create your own syntax files, and you want to have Vim use these automatically with ":syntax enable", do this:

1. Create your user runtime directory. You would normally use the first item of the '[runtimepath](#)' option. Example for Unix:

```
mkdir ~/.vim
```

2. Create a directory in there called "syntax". For Unix:

```
mkdir ~/.vim/syntax
```

3. Write the Vim syntax file. Or download one from the internet. Then write it in your syntax directory. For example, for the "mine" syntax:

```
:w ~/.vim/syntax/mine.vim
```

Now you can start using your syntax file manually:

```
:set syntax=mime
```

You don't have to exit Vim to use this.

If you also want Vim to detect the type of file, see [new-filetype](#) .

If you are setting up a system with many users and you don't want each user to add the same syntax file, you can use another directory from ['runtimepath'](#) .

## ADDING TO AN EXISTING SYNTAX FILE

[mysyntaxfile-add](#)

If you are mostly satisfied with an existing syntax file, but would like to add a few items or change the highlighting, follow these steps:

1. Create your user directory from ['runtimepath'](#) , see above.
2. Create a directory in there called "after/syntax". For Unix:  

```
mkdir -p ~/.vim/after/syntax
```
3. Write a Vim script that contains the commands you want to use. For example, to change the colors for the C syntax:  

```
highlight cComment ctermfg=Green guifg=Green
```
4. Write that file in the "after/syntax" directory. Use the name of the syntax, with ".vim" added. For our C syntax:  

```
:w ~/.vim/after/syntax/c.vim
```

That's it. The next time you edit a C file the Comment color will be different. You don't even have to restart Vim.

If you have multiple files, you can use the filetype as the directory name. All the "\*.vim" files in this directory will be used, for example:

```
~/.vim/after/syntax/c/one.vim
~/.vim/after/syntax/c/two.vim
```

## REPLACING AN EXISTING SYNTAX FILE

[mysyntaxfile-replace](#)

If you don't like a distributed syntax file, or you have downloaded a new version, follow the same steps as for [mysyntaxfile](#) above. Just make sure that you write the syntax file in a directory that is early in ['runtimepath'](#) . Vim will only load the first syntax file found, assuming that it sets `b:current_syntax` .

## NAMING CONVENTIONS

[group-name](#) {[group-name](#)} E669 W18

A syntax group name is to be used for syntax items that match the same kind of thing. These are then linked to a highlight group that specifies the color. A syntax group name doesn't specify any color or attributes itself.

The name for a highlight or syntax group must consist of ASCII letters,

digits, underscores, dots, or hyphens. As a regexp: "[a-zA-Z0-9\_.-]\*". However, Vim does not give an error when using other characters. The maximum length of a group name is about 200 bytes. [E1249](#)

To be able to allow each user to pick their favorite set of colors, there must be preferred names for highlight groups that are common for many languages. These are the suggested group names (if syntax highlighting works properly you can see the actual color, except for "Ignore"):

*Comment	any comment
*Constant	any constant
String	a string constant: "this is a string"
Character	a character constant: 'c', '\n'
Number	a number constant: 234, 0xff
Boolean	a boolean constant: TRUE, false
Float	a floating point constant: 2.3e10
*Identifier	any variable name
Function	function name (also: methods for classes)
*Statement	any statement
Conditional	if, then, else, endif, switch, etc.
Repeat	for, do, while, etc.
Label	case, default, etc.
Operator	"sizeof", "+", "*", etc.
Keyword	any other keyword
Exception	try, catch, throw
*PreProc	generic Preprocessor
Include	preprocessor #include
Define	preprocessor #define
Macro	same as Define
PreCondit	preprocessor #if, #else, #endif, etc.
*Type	int, long, char, etc.
StorageClass	static, register, volatile, etc.
Structure	struct, union, enum, etc.
Typedef	A typedef
*Special	any special symbol
SpecialChar	special character in a constant
Tag	you can use <b>CTRL-]</b> on this
Delimiter	character that needs attention
SpecialComment	special things inside a comment
Debug	debugging statements
*Underlined	text that stands out, HTML links
*Ignore	left blank, hidden <a href="#">hl-Ignore</a>
*Error	any erroneous construct
*Todo	anything that needs extra attention; mostly the

keywords TODO FIXME and XXX

*Added	added line in a diff
*Changed	changed line in a diff
*Removed	removed line in a diff

The names marked with \* are the preferred groups; the others are minor groups. For the preferred groups, the "syntax.vim" file contains default highlighting. The minor groups are linked to the preferred groups, so they get the same highlighting. You can override these defaults by using ":highlight" commands after sourcing the "syntax.vim" file.

**Note** that highlight group names are not case sensitive. "String" and "string" can be used for the same group.

The following names are reserved and cannot be used as a group name:

NONE ALL ALLBUT contains contained

hl-Ignore

When using the Ignore group, you may also consider using the conceal mechanism. See [conceal](#) .

---

### 3. Syntax loading procedure

syntax-loading

This explains the details that happen when the command ":syntax enable" is issued. When Vim initializes itself, it finds out where the runtime files are located. This is used here as the variable `$VIMRUNTIME` .

":syntax enable" and ":syntax on" do the following:

```
Source $VIMRUNTIME/syntax/syntax.vim
|
+- Clear out any old syntax by sourcing $VIMRUNTIME/syntax/nosyntax.vim
|
+- Source first syntax/synload.vim in 'runtimepath'
|
| +- Setup the colors for syntax highlighting. If a color scheme is
| | defined it is loaded again with ":colors {name}". Otherwise
| | ":runtime! syntax/syncolor.vim" is used. ":syntax on" overrules
| | existing colors, ":syntax enable" only sets groups that weren't
| | set yet.
|
| +- Set up syntax autocmds to load the appropriate syntax file when
| | the 'syntax' option is set. synload-1
|
| +- Source the user's optional file, from the mysyntaxfile variable.
| | This is for backwards compatibility with Vim 5.x only. synload-2
|
+- Do ":filetype on", which does ":runtime! filetype.vim". It loads any
| filetype.vim files found. It should always Source
| $VIMRUNTIME/filetype.vim, which does the following.
|
| +- Install autocmds based on suffix to set the 'filetype' option
```

- | | This is where the connection between file name and file type is made for known file types. `synload-3`
- +-- Source the user's optional file, from the `myfiletypefile` variable. This is for backwards compatibility with Vim 5.x only. `synload-4`
- +-- Install one autocommand which sources `scripts.vim` when no file type was detected yet. `synload-5`
- +-- Source `$VIMRUNTIME/menu.vim`, to setup the Syntax menu. `menu.vim`
- +-- Install a FileType autocommand to set the `'syntax'` option when a file type has been detected. `synload-6`
- +-- Execute syntax autocommands to start syntax highlighting for each already loaded buffer.

Upon loading a file, Vim finds the relevant syntax file as follows:

Loading the file triggers the BufReadPost autocommands.

- +-- If there is a match with one of the autocommands from `synload-3` (known file types) or `synload-4` (user's file types), the `'filetype'` option is set to the file type.
- +-- The autocommand at `synload-5` is triggered. If the file type was not found yet, then `scripts.vim` is searched for in `'runtimepath'`. This should always load `$VIMRUNTIME/scripts.vim`, which does the following.
  - +-- Source the user's optional file, from the `myscriptsfile` variable. This is for backwards compatibility with Vim 5.x only.
  - +-- If the file type is still unknown, check the contents of the file, again with checks like `"getline(1) =~ pattern"` as to whether the file type can be recognized, and set `'filetype'`.
- +-- When the file type was determined and `'filetype'` was set, this triggers the FileType autocommand `synload-6` above. It sets `'syntax'` to the determined file type.
- +-- When the `'syntax'` option was set above, this triggers an autocommand from `synload-1` (and `synload-2`). This find the main syntax file in `'runtimepath'`, with this command:
 

```
runtime! syntax/<name>.vim
```
- +-- Any other user installed FileType or Syntax autocommands are triggered. This can be used to change the highlighting for a specific syntax.

---

#### 4. Conversion to HTML

`2html.vim` `convert-to-HTML`

2html is not a syntax file itself, but a script that converts the current window into HTML. Vim opens a new window in which it builds the HTML file.

After you save the resulting file, you can view it with any browser. The colors should be exactly the same as you see them in Vim. With `g:html_line_ids` you can jump to specific lines by adding (for example) #L123 or #123 to the end of the URL in your browser's address bar. And with `g:html_dynamic_folds` enabled, you can show or hide the text that is folded in Vim.

You are not supposed to set the `'filetype'` or `'syntax'` option to "2html"! Source the script to convert the current file:

```
:runtime! syntax/2html.vim
```

Many variables affect the output of 2html.vim; see below. Any of the on/off options listed below can be enabled or disabled by setting them explicitly to the desired value, or restored to their default by removing the variable using `:unlet .`

Remarks:

- Some truly ancient browsers may not show the background colors.
- From most browsers you can also print the file (in color)!
- The latest TOhtml may actually work with older versions of Vim, but some features such as conceal support will not function, and the colors may be incorrect for an old Vim without GUI support compiled in.

Here is an example how to run the script over all .c and .h files from a Unix shell:

```
for f in *.c; do gvim -f +"syn on" +"run! syntax/2html.vim" +"wq" +"q" $f; done
```

To restrict the conversion to a range of lines, use a range with the `:TOhtml` command below, or set `g:html_start_line` and `g:html_end_line` to the first and last line to be converted. Example, using the last set Visual area:

```
:let g:html_start_line = line("<")
:let g:html_end_line = line(">")
:runtime! syntax/2html.vim
```

`:TOhtml`

`:[range]TOhtml` The `":TOhtml"` command is defined in a standard plugin. This command will source `2html.vim` for you. When a range is given, this command sets `g:html_start_line` and `g:html_end_line` to the start and end of the range, respectively. Default range is the entire buffer.

If the current window is part of a `diff`, unless `g:html_diff_one_file` is set, `:TOhtml` will convert all windows which are part of the diff in the current tab and place them side-by-side in a `<table>` element in the generated HTML. With `g:html_line_ids` you can jump to lines in specific windows with (for example)

#W1L42 for line 42 in the first diffed window, or  
#W3L87 for line 87 in the third.

Examples:

```
:10,40T0html " convert lines 10-40 to html
:'<,'>T0html " convert current/last visual selection
:T0html " convert entire buffer
```

`g:html_diff_one_file`

Default: 0.

When 0, and using `:T0html` all windows involved in a `diff` in the current tab page are converted to HTML and placed side-by-side in a `<table>` element. When 1, only the current buffer is converted.

Example:

```
let g:html_diff_one_file = 1
```

`g:html_whole_filler`

Default: 0.

When 0, if `g:html_diff_one_file` is 1, a sequence of more than 3 filler lines is displayed as three lines with the middle line mentioning the total number of inserted lines.

When 1, always display all inserted lines as if `g:html_diff_one_file` were not set.

```
:let g:html_whole_filler = 1
```

`T0html-performance` `g:html_no_progress`

Default: 0.

When 0, display a progress bar in the statusline for each major step in the `2html.vim` conversion process.

When 1, do not display the progress bar. This offers a minor speed improvement but you won't have any idea how much longer the conversion might take; for big files it can take a long time!

Example:

```
let g:html_no_progress = 1
```

You can obtain better performance improvements by also instructing Vim to not run interactively, so that too much time is not taken to redraw as the script moves through the buffer, switches windows, and the like:

```
vim -E -s -c "let g:html_no_progress=1" -c "syntax on" -c "set ft=c" -c "runtime syntax/2
```

**Note** that the `-s` flag prevents loading your `.vimrc` and any plugins, so you need to explicitly source/enable anything that will affect the HTML conversion. See `-E` and `-s-ex` for details. It is probably best to create a script to replace all the `-c` commands and use it with the `-u` flag instead of specifying each command separately.

`hl-T0htmlProgress` `T0html-progress-color`

When displayed, the progress bar will show colored boxes along the statusline as the HTML conversion proceeds. By default, the background color as the

current "DiffDelete" highlight group is used. If "DiffDelete" and "StatusLine" have the same background color, TOhtml will automatically adjust the color to differ. If you do not like the automatically selected colors, you can define your own highlight colors for the progress bar. Example:

```
hi TOhtmlProgress guifg=#c0ffee ctermfg=7
```

`g:html_number_lines`

Default: Current '`number`' setting.

When 0, buffer text is displayed in the generated HTML without line numbering. When 1, a column of line numbers is added to the generated HTML with the same highlighting as the line number column in Vim ( `hl-LineNr` ).

Force line numbers even if '`number`' is not set:

```
:let g:html_number_lines = 1
```

Force to omit the line numbers:

```
:let g:html_number_lines = 0
```

Go back to the default to use '`number`' by deleting the variable:

```
:unlet g:html_number_lines
```

`g:html_line_ids`

Default: 1 if `g:html_number_lines` is set, 0 otherwise.

When 1, adds an HTML id attribute to each line number, or to an empty `<span>` inserted for that purpose if no line numbers are shown. This ID attribute takes the form of L123 for single-buffer HTML pages, or W2L123 for diff-view pages, and is used to jump to a specific line (in a specific window of a diff view). Javascript is inserted to open any closed dynamic folds

( `g:html_dynamic_folds` ) containing the specified line before jumping. The javascript also allows omitting the window ID in the url, and the leading L. For example:

```
page.html#L123 jumps to line 123 in a single-buffer file
page.html#123 does the same
```

```
diff.html#W1L42 jumps to line 42 in the first window in a diff
diff.html#42 does the same
```

`g:html_use_css`

Default: 1.

When 1, generate valid HTML 5 markup with CSS styling, supported in all modern browsers and many old browsers.

When 0, generate `<font>` tags and similar outdated markup. This is not recommended but it may work better in really old browsers, email clients, forum posts, and similar situations where basic CSS support is unavailable.

Example:

```
:let g:html_use_css = 0
```

`g:html_ignore_conceal`

Default: 0.

When 0, concealed text is removed from the HTML and replaced with a character from `:syn-cchar` or '`listchars`' as appropriate, depending on the current value of '`conceallevel`'.

When 1, include all text from the buffer in the generated HTML, even if it is `conceal` ed.

Either of the following commands will ensure that all text in the buffer is included in the generated HTML (unless it is folded):

```
:let g:html_ignore_conceal = 1
:setl conceallevel=0
```

[g:html\\_ignore\\_folding](#)

Default: 0.

When 0, text in a closed fold is replaced by the text shown for the fold in Vim ( `fold-foldtext` ). See [g:html\\_dynamic\\_folds](#) if you also want to allow the user to expand the fold as in Vim to see the text inside.

When 1, include all text from the buffer in the generated HTML; whether the text is in a fold has no impact at all. [g:html\\_dynamic\\_folds](#) has no effect.

Either of these commands will ensure that all text in the buffer is included in the generated HTML (unless it is concealed):

```
zR
:let g:html_ignore_folding = 1
```

[g:html\\_dynamic\\_folds](#)

Default: 0.

When 0, text in a closed fold is not included at all in the generated HTML.

When 1, generate javascript to open a fold and show the text within, just like in Vim.

Setting this variable to 1 causes 2html.vim to always use CSS for styling, regardless of what [g:html\\_use\\_css](#) is set to.

This variable is ignored when [g:html\\_ignore\\_folding](#) is set.

```
:let g:html_dynamic_folds = 1
```

[g:html\\_no\\_foldcolumn](#)

Default: 0.

When 0, if [g:html\\_dynamic\\_folds](#) is 1, generate a column of text similar to Vim's `foldcolumn` ( `fold-foldcolumn` ) the user can click on to toggle folds open or closed. The minimum width of the generated text column is the current **'foldcolumn'** setting.

When 1, do not generate this column; instead, hovering the mouse cursor over folded text will open the fold as if [g:html\\_hover\\_unfold](#) were set.

```
:let g:html_no_foldcolumn = 1
```

[T0html-uncopyable-text](#) [g:html\\_prevent\\_copy](#)

Default: Empty string.

This option prevents certain regions of the generated HTML from being copied, when you select all text in document rendered in a browser and copy it. Useful for allowing users to copy-paste only the source text even if a fold column or line numbers are shown in the generated content. Specify regions to be affected in this way as follows:

```
f: fold column
n: line numbers (also within fold text)
t: fold text
d: diff filler
```

Example, to make the fold column and line numbers uncopyable:

```
:let g:html_prevent_copy = "fn"
```

The method used to prevent copying in the generated page depends on the value of `g:html_use_input_for_pc`.

`g:html_use_input_for_pc`

Default: "none"

If `g:html_prevent_copy` is non-empty, then:

When "all", read-only `<input>` elements are used in place of normal text for uncopyable regions. In some browsers, especially older browsers, after selecting an entire page and copying the selection, the `<input>` tags are not pasted with the page text. If `g:html_no_invalid` is 0, the `<input>` tags have invalid type; this works in more browsers, but the page will not validate.

**Note:** This method does NOT work in recent versions of Chrome and equivalent browsers; the `<input>` tags get pasted with the text.

When "fallback" (default value), the same `<input>` elements are generated for older browsers, but newer browsers (detected by CSS feature query) hide the `<input>` elements and instead use generated content in an `::before` pseudoelement to display the uncopyable text. This method should work with the largest number of browsers, both old and new.

When "none", the `<input>` elements are not generated at all. Only the generated-content method is used. This means that old browsers, notably Internet Explorer, will either copy the text intended not to be copyable, or the non-copyable text may not appear at all. However, this is the most standards-based method, and there will be much less markup.

`g:html_no_invalid`

Default: 0.

When 0, if `g:html_prevent_copy` is non-empty and `g:html_use_input_for_pc` is not "none", an invalid attribute is intentionally inserted into the `<input>` element for the uncopyable areas. This prevents pasting the `<input>` elements in some applications. Specifically, some versions of Microsoft Word will not paste the `<input>` elements if they contain this invalid attribute. When 1, no invalid markup is inserted, and the generated page should validate. However, `<input>` elements may be pasted into some applications and can be difficult to remove afterward.

`g:html_hover_unfold`

Default: 0.

When 0, the only way to open a fold generated by 2html.vim with `g:html_dynamic_folds` set, is to click on the generated fold column.

When 1, use CSS 2.0 to allow the user to open a fold by moving the mouse cursor over the displayed fold text. This is useful to allow users with disabled javascript to view the folded text.

**Note** that old browsers (notably Internet Explorer 6) will not support this feature. Browser-specific markup for IE6 is included to fall back to the normal CSS1 styling so that the folds show up correctly for this browser, but they will not be openable without a foldcolumn.

```
:let g:html_hover_unfold = 1
```

[g:html\\_id\\_expr](#)

Default: ""

Dynamic folding and jumping to line IDs rely on unique IDs within the document to work. If generated HTML is copied into a larger document, these IDs are no longer guaranteed to be unique. Set `g:html_id_expr` to an expression Vim can evaluate to get a unique string to append to each ID used in a given document, so that the full IDs will be unique even when combined with other content in a larger HTML document. Example, to append `_` and the buffer number to each ID:

```
:let g:html_id_expr = '"_" .. bufnr("%")'
```

To append a string `"_mystring"` to the end of each ID:

```
:let g:html_id_expr = '"_mystring"'
```

**Note:** When converting a diff view to HTML, the expression will only be evaluated for the first window in the diff, and the result used for all the windows.

[TOhtml-wrap-text](#) [g:html\\_pre\\_wrap](#)

Default: Current `'wrap'` setting.

When 0, if `g:html_no_pre` is 0 or unset, the text in the generated HTML does not wrap at the edge of the browser window.

When 1, if `g:html_use_css` is 1, the CSS 2.0 "white-space:pre-wrap" value is used, causing the text to wrap at whitespace at the edge of the browser window.

Explicitly enable text wrapping:

```
:let g:html_pre_wrap = 1
```

Explicitly disable wrapping:

```
:let g:html_pre_wrap = 0
```

Go back to default, determine wrapping from `'wrap'` setting:

```
:unlet g:html_pre_wrap
```

[g:html\\_no\\_pre](#)

Default: 0.

When 0, buffer text in the generated HTML is surrounded by `<pre>...</pre>` tags. Series of whitespace is shown as in Vim without special markup, and tab characters can be included literally (see [g:html\\_expand\\_tabs](#)).

When 1 (not recommended), the `<pre>` tags are omitted, and a plain `<div>` is used instead. Whitespace is replaced by a series of `&nbsp;` character references, and `<br>` is used to end each line. This is another way to allow text in the generated HTML to wrap (see [g:html\\_pre\\_wrap](#)) which also works in old browsers, but may cause noticeable differences between Vim's display and the rendered page generated by `2html.vim`.

```
:let g:html_no_pre = 1
```

[g:html\\_no\\_doc](#)

Default: 0.

When 1 it doesn't generate a full HTML document with a DOCTYPE, `<head>`, `<body>`, etc. If `g:html_use_css` is enabled (the default) you'll have to define the CSS manually. The `g:html_dynamic_folds` and `g:html_line_ids`

settings (off by default) also insert some JavaScript.

`g:html_no_links`

Default: 0.

Don't generate `<a>` tags for text that looks like an URL.

`g:html_no_modeline`

Default: 0.

Don't generate a modeline disabling folding.

`g:html_expand_tabs`

Default: 0 if `'tabstop'` is 8, `'expandtab'` is 0, `'vartabstop'` is not in use, and no fold column or line numbers occur in the generated HTML; 1 otherwise.

When 1, `<Tab>` characters in the buffer text are replaced with an appropriate number of space characters, or `&nbsp;` references if `g:html_no_pre` is 1.

When 0, if `g:html_no_pre` is 0 or unset, `<Tab>` characters in the buffer text are included as-is in the generated HTML. This is useful for when you want to allow copy and paste from a browser without losing the actual whitespace in the source document. **Note** that this can easily break text alignment and indentation in the HTML, unless set by default.

Force `2html.vim` to keep `<Tab>` characters:

```
:let g:html_expand_tabs = 0
```

Force tabs to be expanded:

```
:let g:html_expand_tabs = 1
```

`T0html-encoding-detect` `T0html-encoding`

It is highly recommended to set your desired encoding with `g:html_use_encoding` for any content which will be placed on a web server.

If you do not specify an encoding, `2html.vim` uses the preferred IANA name for the current value of `'fileencoding'` if set, or `'encoding'` if not.

`'encoding'` is always used for certain `'buftype'` values. `'fileencoding'` will be set to match the chosen document encoding.

Automatic detection works for the encodings mentioned specifically by name in `encoding-names`, but `T0html` will only automatically use those encodings with wide browser support. However, you can override this to support specific encodings that may not be automatically detected by default (see options below). See <http://www.iana.org/assignments/character-sets> for the IANA names.

**Note:** By default all Unicode encodings are converted to UTF-8 with no BOM in the generated HTML, as recommended by W3C:

<http://www.w3.org/International/questions/qa-choosing-encodings>

<http://www.w3.org/International/questions/qa-byte-order-mark>

`g:html_use_encoding`

Default: none, uses IANA name for current `'fileencoding'` as above.

To overrule all automatic charset detection, set `g:html_use_encoding` to the name of the charset to be used. It is recommended to set this variable to

something widely supported, like UTF-8, for anything you will be hosting on a webserver:

```
:let g:html_use_encoding = "UTF-8"
```

You can also use this option to omit the line that specifies the charset entirely, by setting `g:html_use_encoding` to an empty string (NOT recommended):

```
:let g:html_use_encoding = ""
```

To go back to the automatic mechanism, delete the `g:html_use_encoding` variable:

```
:unlet g:html_use_encoding
```

`g:html_encoding_override`

Default: none, `autoload/tohtml.vim` contains default conversions for encodings mentioned by name at `encoding-names`.

This option allows `2html.vim` to detect the correct `'fileencoding'` when you specify an encoding with `g:html_use_encoding` which is not in the default list of conversions.

This is a dictionary of charset-encoding pairs that will replace existing pairs automatically detected by `TOhtml`, or supplement with new pairs.

Detect the HTML charset "windows-1252" as the encoding "8bit-cp1252":

```
:let g:html_encoding_override = {'windows-1252': '8bit-cp1252'}
```

`g:html_charset_override`

Default: none, `autoload/tohtml.vim` contains default conversions for encodings mentioned by name at `encoding-names` and which have wide browser support.

This option allows `2html.vim` to detect the HTML charset for any `'fileencoding'` or `'encoding'` which is not detected automatically. You can also use it to override specific existing encoding-charset pairs. For example, `TOhtml` will by default use UTF-8 for all Unicode/UCS encodings. To use UTF-16 and UTF-32 instead, use:

```
:let g:html_charset_override = {'ucs-4': 'UTF-32', 'utf-16': 'UTF-16'}
```

**Note** that documents encoded in either UTF-32 or UTF-16 have known compatibility problems with some major browsers.

`g:html_font`

Default: "monospace"

You can specify the font or fonts used in the converted document using `g:html_font`. If this option is set to a string, then the value will be surrounded with single quotes. If this option is set to a list then each list item is surrounded by single quotes and the list is joined with commas. Either way, "monospace" is added as the fallback generic family name and the entire result used as the font family (using CSS) or font face (if not using CSS).

Examples:

```
" font-family: 'Consolas', monospace;
```

```
:let g:html_font = "Consolas"
```

```
" font-family: 'DejaVu Sans Mono', 'Consolas', monospace;
```

```
:let g:html_font = ["DejaVu Sans Mono", "Consolas"]
```

`convert-to-XML`   `convert-to-XHTML`   `g:html_use_xhtml`

Default: 0.

When 0, generate standard HTML 4.01 (strict when possible).

When 1, generate XHTML 1.0 instead (XML compliant HTML).

```
:let g:html_use_xhtml = 1
```

---

5. Syntax file remarks

[:syn-file-remarks](#)

[b:current\\_syntax-variable](#)

Vim stores the name of the syntax that has been loaded in the "b:current\_syntax" variable. You can use this if you want to load other settings, depending on which syntax is active. Example:

```
:au BufReadPost * if b:current_syntax == "csh"
:au BufReadPost * do-some-things
:au BufReadPost * endif
```

## ABEL

[abel.vim](#) [ft-abel-syntax](#)

ABEL highlighting provides some user-defined options. To enable them, assign any value to the respective variable. Example:

```
:let abel_obsolete_ok=1
```

To disable them use ":unlet". Example:

```
:unlet abel_obsolete_ok
```

### Variable

abel\_obsolete\_ok

abel\_cpp\_comments\_illegal

### Highlight

obsolete keywords are statements, not errors

do not interpret '//' as inline comment leader

ADA

See [ft-ada-syntax](#)

## ANT

[ant.vim](#) [ft-ant-syntax](#)

The ant syntax file provides syntax highlighting for javascript and python by default. Syntax highlighting for other script languages can be installed by the function AntSyntaxScript(), which takes the tag name as first argument and the script syntax file name as second argument. Example:

```
:call AntSyntaxScript('perl', 'perl.vim')
```

will install syntax perl highlighting for the following ant code

```
<script language = 'perl'><![CDATA[
everything inside is highlighted as perl
]]></script>
```

See [mysyntaxfile-add](#) for installing script languages permanently.

## APACHE

apache.vim ft-apache-syntax

The apache syntax file provides syntax highlighting for Apache HTTP server version 2.2.3.

## ASSEMBLY

asm.vim asmh8300.vim nasm.vim masm.vim asm68k  
ft-asm-syntax ft-asmh8300-syntax ft-nasm-syntax  
ft-masm-syntax ft-asm68k-syntax fasm.vim

Files matching "\*.i" could be Progress or Assembly. If the automatic detection doesn't work for you, or you don't edit Progress at all, use this in your startup vimrc:

```
:let filetype_i = "asm"
```

Replace "asm" with the type of assembly you use.

There are many types of assembly languages that all use the same file name extensions. Therefore you will have to select the type yourself, or add a line in the assembly file that Vim will recognize. Currently these syntax files are included:

asm	GNU assembly (usually have .s or .S extension and were already built using C compiler such as GCC or CLANG)
asm68k	Motorola 680x0 assembly
asmh8300	Hitachi H-8300 version of GNU assembly
ia64	Intel Itanium 64
fasm	Flat assembly ( <a href="http://flatassembler.net">http://flatassembler.net</a> )
masm	Microsoft assembly (.masm files are compiled with Microsoft's Macro Assembler. This is only supported for x86, x86_64, ARM and AARCH64 CPU families)
nasm	Netwide assembly
tasm	Turbo Assembly (with opcodes 80x86 up to Pentium, and MMX)
pic	PIC assembly (currently for PIC16F84)

The most flexible is to add a line in your assembly file containing:

```
asmsyntax=nasm
```

Replace "nasm" with the name of the real assembly syntax. This line must be one of the first five lines in the file. No non-white text must be immediately before or after this text. **Note** that specifying asmsyntax=foo is equivalent to setting ft=foo in a [modeline](#), and that in case of a conflict between the two settings the one from the modeline will take precedence (in particular, if you have ft=asm in the modeline, you will get the GNU syntax highlighting regardless of what is specified as asmsyntax).

The syntax type can always be overruled for a specific buffer by setting the b:asmsyntax variable:

```
:let b:asmsyntax = "nasm"
```

If b:asmsyntax is not set, either automatically or by hand, then the value of the global variable asmsyntax is used. This can be seen as a default assembly language:

```
:let asmsyntax = "nasm"
```

As a last resort, if nothing is defined, the "asm" syntax is used.

### Netwide assembler (nasm.vim) optional highlighting

To enable a feature:

```
:let {variable}=1|set syntax=nasm
```

To disable a feature:

```
:unlet {variable} |set syntax=nasm
```

Variable	Highlight
nasm_loose_syntax	unofficial parser allowed syntax not as Error (parser dependent; not recommended)
nasm_ctx_outside_macro	contexts outside macro not as Error
nasm_no_warn	potentially risky syntax not as ToDo

**ASTRO** [astro.vim](#) [ft-astro-syntax](#)

### Configuration

The following variables control certain syntax highlighting features. You can add them to your .vimrc.

To enable TypeScript and TSX for ".astro" files (default "disable"):

```
let g:astro_typescript = "enable"
```

To enable Stylus for ".astro" files (default "disable"):

```
let g:astro_style = "enable"
```

**NOTE:** You need to install an external plugin to support stylus in astro files.

**ASPPERL** [ft-asperl-syntax](#)  
**ASPVBS** [ft-aspvbs-syntax](#)

\*.asp and \*.asa files could be either Perl or Visual Basic script. Since it's hard to detect this you can set two global variables to tell Vim what you are using. For Perl script use:

```
:let g:filetype_asa = "asperl"
:let g:filetype_asp = "asperl"
```

For Visual Basic use:

```
:let g:filetype_asa = "aspvbs"
:let g:filetype_asp = "aspvbs"
```

**ASYMPTOTE** [asy.vim](#) [ft-asy-syntax](#)

By default, only basic Asymptote keywords are highlighted. To highlight extended geometry keywords:

```
:let g:asy_syn_plain = 1
```

and for highlighting keywords related to 3D constructions:

```
:let g:asy_syn_three = 1
```

By default, Asymptote-defined colors (e.g: lightblue) are highlighted. To highlight TeX-defined colors (e.g: BlueViolet) use:

```
:let g:asy_syn_texcolors = 1
```

or for Xorg colors (e.g: AliceBlue):

```
:let g:asy_syn_x11colors = 1
```

## BAAN

[baan.vim](#) [baan-syntax](#)

The `baan.vim` gives syntax support for BaanC of release BaanIV up to SSA ERP LN for both 3 GL and 4 GL programming. Large number of standard defines/constants are supported.

Some special violation of coding standards will be signalled when one specify in ones `.vimrc` :

```
let baan_code_stds=1
```

### baan-folding

Syntax folding can be enabled at various levels through the variables mentioned below (Set those in your `.vimrc` ). The more complex folding on source blocks and SQL can be CPU intensive.

To allow any folding and enable folding at function level use:

```
let baan_fold=1
```

Folding can be enabled at source block level as if, while, for ,... The indentation preceding the begin/end keywords has to match (spaces are not considered equal to a tab).

```
let baan_fold_block=1
```

Folding can be enabled for embedded SQL blocks as SELECT, SELECTD0, SELECTEMPTY, ... The indentation preceding the begin/end keywords has to match (spaces are not considered equal to a tab).

```
let baan_fold_sql=1
```

**Note:** Block folding can result in many small folds. It is suggested to `:set` the options `'foldminlines'` and `'foldnestmax'` in `.vimrc` or use `:setlocal` in `.../after/syntax/baan.vim` (see [after-directory](#) ). Eg:

```
set foldminlines=5
```

```
set foldnestmax=6
```

## BASIC

[basic.vim](#) [vb.vim](#) [ft-basic-syntax](#) [ft-vb-syntax](#)

Both Visual Basic and "normal" BASIC use the extension ".bas". To detect which one should be used, Vim checks for the string "VB\_Name" in the first five lines of the file. If it is not found, filetype will be "basic", otherwise "vb". Files with the ".frm" extension will always be seen as Visual Basic.

If the automatic detection doesn't work for you or you only edit, for example, FreeBASIC files, use this in your startup vimrc:

```
:let filetype_bas = "freebasic"
```

## C

c.vim ft-c-syntax

A few things in C highlighting are optional. To enable them assign any value (including zero) to the respective variable. Example:

```
:let c_comment_strings = 1
:let c_no_bracket_error = 0
```

To disable them use `:unlet`. Example:

```
:unlet c_comment_strings
```

Setting the value to zero doesn't work!

An alternative is to switch to the C++ highlighting:

```
:set filetype=cpp
```

Variable	Highlight
c_gnu	GNU gcc specific items
c_comment_strings	strings and numbers inside a comment
c_space_errors	trailing white space and spaces before a <Tab>
c_no_trail_space_error	... but no trailing spaces
c_no_tab_space_error	... but no spaces before a <Tab>
c_no_bracket_error	don't highlight {}; inside [] as errors
c_no_curly_error	don't highlight {}; inside [] and () as errors; ...except { and } in first column Default is to highlight them, otherwise you can't spot a missing ")".
c_curly_error	highlight a missing } by finding all pairs; this forces syncing from the start of the file, can be slow
c_no_ansi	don't do standard ANSI types and constants
c_ansi_typedefs	... but do standard ANSI types
c_ansi_constants	... but do standard ANSI constants
c_no_utf	don't highlight \u and \U in strings
c_syntax_for_h	for *.h files use C syntax instead of C++ and use objc syntax instead of objc++
c_no_if0	don't highlight "#if 0" blocks as comments
c_no_cformat	don't highlight %-formats in strings
c_no_c99	don't highlight C99 standard items
c_no_c11	don't highlight C11 standard items
c_no_c23	don't highlight C23 standard items
c_no_bsd	don't highlight BSD specific types
c_functions	highlight function calls and definitions
c_function_pointers	highlight function pointers definitions

When '**foldmethod**' is set to "syntax" then /\* \*/ comments and { } blocks will become a fold. If you don't want comments to become a fold use:

```
:let c_no_comment_fold = 1
```

"#if 0" blocks are also folded, unless:

```
:let c_no_if0_fold = 1
```

If you notice highlighting errors while scrolling backwards, which are fixed when redrawing with **CTRL-L**, try setting the "c\_minlines" internal variable to a larger number:

```
:let c_minlines = 100
```

This will make the syntax synchronization start 100 lines before the first

displayed line. The default value is 50 (15 when `c_no_if0` is set). The disadvantage of using a larger number is that redrawing can become slow.

When using the `"#if 0" / "#endif"` comment highlighting, notice that this only works when the `"#if 0"` is within `"c_minlines"` from the top of the window. If you have a long `"#if 0"` construct it will not be highlighted correctly.

To match extra items in comments, use the `cCommentGroup` cluster.

Example:

```
:au Syntax c call MyCadd()
:function MyCadd()
: syn keyword cMyItem contained Ni
: syn cluster cCommentGroup add=cMyItem
: hi link cMyItem Title
:endfun
```

ANSI constants will be highlighted with the `"cConstant"` group. This includes `"NULL"`, `"SIG_IGN"` and others. But not `"TRUE"`, for example, because this is not in the ANSI standard. If you find this confusing, remove the `cConstant` highlighting:

```
:hi link cConstant NONE
```

If you see `'{'` and `'}'` highlighted as an error where they are OK, reset the highlighting for `cErrInParen` and `cErrInBracket`.

If you want to use folding in your C files, you can add these lines in a file in the `"after"` directory in `'runtimepath'`. For Unix this would be `~/.vim/after/syntax/c.vim`.

```
syn sync fromstart
set foldmethod=syntax
```

## CH

`ch.vim` `ft-ch-syntax`

C/C++ interpreter. Ch has similar syntax highlighting to C and builds upon the C syntax file. See `c.vim` for all the settings that are available for C.

By setting a variable you can tell Vim to use Ch syntax for `*.h` files, instead of C or C++:

```
:let ch_syntax_for_h = 1
```

## CHILL

`chill.vim` `ft-chill-syntax`

Chill syntax highlighting is similar to C. See `c.vim` for all the settings that are available. Additionally there is:

<code>chill_space_errors</code>	like <code>c_space_errors</code>
<code>chill_comment_string</code>	like <code>c_comment_strings</code>
<code>chill_minlines</code>	like <code>c_minlines</code>

## CHANGELOG

`changelog.vim` `ft-changelog-syntax`

ChangeLog supports highlighting spaces at the start of a line.

If you do not like this, add following line to your `.vimrc`:

```
let g:changelog_spacing_errors = 0
```

This works the next time you edit a changelog file. You can also use `"b:changelog_spacing_errors"` to set this per buffer (before loading the syntax file).

You can change the highlighting used, e.g., to flag the spaces as an error:

```
:hi link ChangelogError Error
```

Or to avoid the highlighting:

```
:hi link ChangelogError NONE
```

This works immediately.

## CLOJURE

`ft-clojure-syntax`

`g:clojure_syntax_keywords`

Syntax highlighting of public vars in `"clojure.core"` is provided by default, but additional symbols can be highlighted by adding them to the

`g:clojure_syntax_keywords` variable. The value should be a `Dictionary` of syntax group names, each containing a `List` of identifiers.

```
let g:clojure_syntax_keywords = {
 \ 'clojureMacro': ["defproject", "defcustom"],
 \ 'clojureFunc': ["string/join", "string/replace"]
 \ }
```

Refer to the Clojure syntax script for valid syntax group names.

There is also `b:clojure_syntax_keywords` which is a buffer-local variant of this variable intended for use by plugin authors to highlight symbols dynamically.

By setting the `b:clojure_syntax_without_core_keywords` variable, vars from `"clojure.core"` will not be highlighted by default. This is useful for namespaces that have set ``(:refer-clojure :only [])``

`g:clojure_fold`

Setting `g:clojure_fold` to ``1`` will enable the folding of Clojure code. Any list, vector or map that extends over more than one line can be folded using the standard Vim `fold-commands`.

`g:clojure_discard_macro`

Set this variable to ``1`` to enable basic highlighting of Clojure's `"discard reader macro"`.

```
#_(defn foo [x]
 (println x))
```

**Note** that this option will not correctly highlight stacked discard macros

(e.g. ``#_#_``).

## COBOL

[cobol.vim](#) [ft-cobol-syntax](#)

COBOL highlighting has different needs for legacy code than it does for fresh development. This is due to differences in what is being done (maintenance versus development) and other factors. To enable legacy code highlighting, add this line to your `.vimrc`:

```
:let cobol_legacy_code = 1
```

To disable it again, use this:

```
:unlet cobol_legacy_code
```

## COLD FUSION

[coldfusion.vim](#) [ft-coldfusion-syntax](#)

The ColdFusion has its own version of HTML comments. To turn on ColdFusion comment highlighting, add the following line to your startup file:

```
:let html_wrong_comments = 1
```

The ColdFusion syntax file is based on the HTML syntax file.

## CPP

[cpp.vim](#) [ft-cpp-syntax](#)

Most things are the same as [ft-c-syntax](#) .

Variable	Highlight
<code>cpp_no_cpp11</code>	don't highlight C++11 standard items
<code>cpp_no_cpp14</code>	don't highlight C++14 standard items
<code>cpp_no_cpp17</code>	don't highlight C++17 standard items
<code>cpp_no_cpp20</code>	don't highlight C++20 standard items

## CSH

[csh.vim](#) [ft-csh-syntax](#)

This covers the shell named "csh". **Note** that on some systems tcsh is actually used.

Detecting whether a file is csh or tcsh is notoriously hard. Some systems symlink `/bin/csh` to `/bin/tcsh`, making it almost impossible to distinguish between csh and tcsh. In case VIM guesses wrong you can set the "filetype\_csh" variable. For using csh: [g:filetype\\_csh](#)

```
:let g:filetype_csh = "csh"
```

For using tcsh:

```
:let g:filetype_csh = "tcsh"
```

Any script with a tcsh extension or a standard tcsh filename (`.tcshrc`, `tcsh.tcshrc`, `tcsh.login`) will have filetype tcsh. All other tcsh/csh scripts will be classified as tcsh, UNLESS the "filetype\_csh" variable exists. If the

"filetype\_csh" variable exists, the filetype will be set to the value of the variable.

## CSV

[ft-csv-syntax](#)

If you change the delimiter of a CSV file, its syntax highlighting will no longer match the changed file content. You will need to unlet the following variable:

```
:unlet b:csv_delimiter
```

And afterwards save and reload the file:

```
:w
:e
```

Now the syntax engine should determine the newly changed CSV delimiter.

## CYNLIB

[cynlib.vim](#) [ft-cynlib-syntax](#)

Cynlib files are C++ files that use the Cynlib class library to enable hardware modelling and simulation using C++. Typically Cynlib files have a .cc or a .cpp extension, which makes it very difficult to distinguish them from a normal C++ file. Thus, to enable Cynlib highlighting for .cc files, add this line to your .vimrc file:

```
:let cynlib_cyntax_for_cc=1
```

Similarly for cpp files (this extension is only usually used in Windows)

```
:let cynlib_cyntax_for_cpp=1
```

To disable these again, use this:

```
:unlet cynlib_cyntax_for_cc
:unlet cynlib_cyntax_for_cpp
```

## CWEB

[cweb.vim](#) [ft-cweb-syntax](#)

Files matching "\*.w" could be Progress or cweb. If the automatic detection doesn't work for you, or you don't edit Progress at all, use this in your startup vimrc:

```
:let filetype_w = "cweb"
```

## CSHARP

[cs.vim](#) [ft-cs-syntax](#)

C# raw string literals may use any number of quote marks to encapsulate the block, and raw interpolated string literals may use any number of braces to encapsulate the interpolation, e.g.

```
$$$""""Hello {{{name}}}"
```

By default, Vim highlights 3-8 quote marks, and 1-8 interpolation braces. The maximum numbers of quotes and braces recognized can be configured using the following variables:

Variable	Default
<code>g:cs_raw_string_quote_count</code>	8
<code>g:cs_raw_string_interpolation_brace_count</code>	8

## **DART** `dart.vim` `ft-dart-syntax`

Dart is an object-oriented, typed, class defined, garbage collected language used for developing mobile, desktop, web, and back-end applications. Dart uses a C-like syntax derived from C, Java, and JavaScript, with features adopted from Smalltalk, Python, Ruby, and others.

More information about the language and its development environment at the official Dart language website at <https://dart.dev>

`dart.vim` syntax detects and highlights Dart statements, reserved words, type declarations, storage classes, conditionals, loops, interpolated values, and comments. There is no support for idioms from Flutter or any other Dart framework.

Changes, fixes? Submit an issue or pull request via:

<https://github.com/pr3d4t0r/dart-vim-syntax/>

## **DESKTOP** `desktop.vim` `ft-desktop-syntax`

Primary goal of this syntax file is to highlight `.desktop` and `.directory` files according to [freedesktop.org](https://freedesktop.org) standard:

<https://specifications.freedesktop.org/desktop-entry-spec/latest/>

To highlight nonstandard extensions that does not begin with X-, set

```
let g:desktop_enable_nonstd = 1
```

Note that this may cause wrong highlight.

To highlight KDE-reserved features, set

```
let g:desktop_enable_kde = 1
```

`g:desktop_enable_kde` follows `g:desktop_enable_nonstd` if not supplied

## **DIFF** `diff.vim`

The diff highlighting normally finds translated headers. This can be slow if there are very long lines in the file. To disable translations:

```
:let diff_translations = 0
```

Also see `diff-slow`.

## **DIRCOLORS** `dircolors.vim` `ft-dircolors-syntax`

The `dircolors` utility highlighting definition has one option. It exists to provide compatibility with the Slackware GNU/Linux distributions version of

the command. It adds a few keywords that are generally ignored by most versions. On Slackware systems, however, the utility accepts the keywords and uses them for processing. To enable the Slackware keywords add the following line to your startup file:

```
let dircolors_is_slackware = 1
```

<b>DOCBOOK</b>	<code>docbk.vim</code>	<code>ft-docbk-syntax</code>	<code>docbook</code>
<b>DOCBOOK XML</b>	<code>docbkxml.vim</code>	<code>ft-docbkxml-syntax</code>	
<b>DOCBOOK SGML</b>	<code>docbksgml.vim</code>	<code>ft-docbksgml-syntax</code>	

There are two types of DocBook files: SGML and XML. To specify what type you are using the "b:docbk\_type" variable should be set. Vim does this for you automatically if it can recognize the type. When Vim can't guess it the type defaults to XML.

You can set the type manually:

```
:let docbk_type = "sgml"
```

or:

```
:let docbk_type = "xml"
```

You need to do this before loading the syntax file, which is complicated. Simpler is setting the filetype to "docbkxml" or "docbksgml":

```
:set filetype=docbksgml
```

or:

```
:set filetype=docbkxml
```

You can specify the DocBook version:

```
:let docbk_ver = 3
```

When not set 4 is used.

<b>DOSBATCH</b>	<code>dosbatch.vim</code>	<code>ft-dosbatch-syntax</code>
-----------------	---------------------------	---------------------------------

Select the set of Windows Command interpreter extensions that should be supported with the variable `dosbatch_cmdextversion`. For versions of Windows NT (before Windows 2000) this should have the value of 1. For Windows 2000 and later it should be 2.

Select the version you want with the following line:

```
:let dosbatch_cmdextversion = 1
```

If this variable is not defined it defaults to a value of 2 to support Windows 2000 and later.

The original MS-DOS supports an idiom of using a double colon (::) as an alternative way to enter a comment line. This idiom can be used with the current Windows Command Interpreter, but it can lead to problems when used inside ( ... ) command blocks. You can find a discussion about this on Stack Overflow -

<https://stackoverflow.com/questions/12407800/which-comment-style-should-i-use-in-batch-fil>

To allow the use of the :: idiom for comments in command blocks with the Windows Command Interpreter set the `dosbatch_colons_comment` variable to anything:

```
:let dosbatch_colons_comment = 1
```

If this variable is set then a `::` comment that is the last line in a command block will be highlighted as an error.

There is an option that covers whether `*.btm` files should be detected as type "dosbatch" (MS-DOS batch files) or type "btm" (4DOS batch files). The latter is used by default. You may select the former with the following line:

```
:let g:dosbatch_syntax_for_btm = 1
```

If this variable is undefined or zero, btm syntax is selected.

## DOXYGEN

[doxygen.vim](#) [doxygen-syntax](#)

Doxygen generates code documentation using a special documentation format (similar to Javadoc). This syntax script adds doxygen highlighting to c, cpp, idl and php files, and should also work with java.

There are a few of ways to turn on doxygen formatting. It can be done explicitly or in a modeline by appending `'.doxygen'` to the syntax of the file. Example:

```
:set syntax=c.doxygen
```

or

```
// vim:syntax=c.doxygen
```

It can also be done automatically for C, C++, C#, IDL and PHP files by setting the global or buffer-local variable `load_doxygen_syntax`. This is done by adding the following to your `.vimrc`.

```
:let g:load_doxygen_syntax=1
```

There are a couple of variables that have an effect on syntax highlighting, and are to do with non-standard highlighting options.

Variable	Default	Effect
<code>g:doxygen_enhanced_color</code> <code>g:doxygen_enhanced_colour</code>	0	Use non-standard highlighting for doxygen comments.
<code>doxygen_my_rendering</code>	0	Disable rendering of HTML bold, italic and <code>html_my_rendering</code> underline.
<code>doxygen_javadoc_autobrief</code>	1	Set to 0 to disable javadoc autobrief colour highlighting.
<code>doxygen_end_punctuation</code>	<code>'[.]'</code>	Set to regexp match for the ending punctuation of brief

There are also some highlight groups worth mentioning as they can be useful in configuration.

Highlight	Effect
-----------	--------

doxygenErrorComment	The colour of an end-comment when missing punctuation in a code, verbatim or dot section
doxygenLinkError	The colour of an end-comment when missing the \endlink from a \link section.

**DTD** dtd.vim ft-dtd-syntax

The DTD syntax highlighting is case sensitive by default. To disable case-sensitive highlighting, add the following line to your startup file:

```
:let dtd_ignore_case=1
```

The DTD syntax file will highlight unknown tags as errors. If this is annoying, it can be turned off by setting:

```
:let dtd_no_tag_errors=1
```

before sourcing the dtd.vim syntax file.

Parameter entity names are highlighted in the definition using the 'Type' highlighting group and 'Comment' for punctuation and '%'. Parameter entity instances are highlighted using the 'Constant' highlighting group and the 'Type' highlighting group for the delimiters % and ;. This can be turned off by setting:

```
:let dtd_no_param_entities=1
```

The DTD syntax file is also included by xml.vim to highlight included dtd's.

**EIFFEL** eiffel.vim ft-eiffel-syntax

While Eiffel is not case-sensitive, its style guidelines are, and the syntax highlighting file encourages their use. This also allows to highlight class names differently. If you want to disable case-sensitive highlighting, add the following line to your startup file:

```
:let eiffel_ignore_case=1
```

Case still matters for class names and TODO marks in comments.

Conversely, for even stricter checks, add one of the following lines:

```
:let eiffel_strict=1
:let eiffel_pedantic=1
```

Setting eiffel\_strict will only catch improper capitalization for the five predefined words "Current", "Void", "Result", "Precursor", and "NONE", to warn against their accidental use as feature or class names.

Setting eiffel\_pedantic will enforce adherence to the Eiffel style guidelines fairly rigorously (like arbitrary mixes of upper- and lowercase letters as well as outdated ways to capitalize keywords).

If you want to use the lower-case version of "Current", "Void", "Result", and "Precursor", you can use

```
:let eiffel_lower_case_predef=1
```

instead of completely turning case-sensitive highlighting off.

Support for ISE's proposed new creation syntax that is already experimentally handled by some compilers can be enabled by:

```
:let eiffel_ise=1
```

Finally, some vendors support hexadecimal constants. To handle them, add

```
:let eiffel_hex_constants=1
```

to your startup file.

## **EUPHORIA**                    [euphoria3.vim](#)    [euphoria4.vim](#)    [ft-euphoria-syntax](#)

Two syntax highlighting files exist for Euphoria. One for Euphoria version 3.1.1, which is the default syntax highlighting file, and one for Euphoria version 4.0.5 or later.

Euphoria version 3.1.1 (<http://www.rapideuphoria.com/> link seems dead) is still necessary for developing applications for the DOS platform, which Euphoria version 4 (<http://www.openeuphoria.org/>) does not support.

The following file extensions are auto-detected as Euphoria file type:

```
*.e, *.eu, *.ew, *.ex, *.exu, *.exw
*.E, *.EU, *.EW, *.EX, *.EXU, *.EXW
```

To select syntax highlighting file for Euphoria, as well as for auto-detecting the \*.e and \*.E file extensions as Euphoria file type, add the following line to your startup file:

```
:let g:filetype_euphoria = "euphoria3"
```

or

```
:let g:filetype_euphoria = "euphoria4"
```

Elixir and Euphoria share the \*.ex file extension. If the filetype is specifically set as Euphoria with the g:filetype\_euphoria variable, or the file is determined to be Euphoria based on keywords in the file, then the filetype will be set as Euphoria. Otherwise, the filetype will default to Elixir.

## **ERLANG**                                            [erlang.vim](#)    [ft-erlang-syntax](#)

Erlang is a functional programming language developed by Ericsson. Files with

the following extensions are recognized as Erlang files: erl, hrl, yaws.

The BIFs (built-in functions) are highlighted by default. To disable this, put the following line in your vimrc:

```
:let g:erlang_highlight_bifs = 0
```

To enable highlighting some special atoms, put this in your vimrc:

```
:let g:erlang_highlight_special_atoms = 1
```

## ELIXIR

`elixir.vim` `ft-elixir-syntax`

Elixir is a dynamic, functional language for building scalable and maintainable applications.

The following file extensions are auto-detected as Elixir file types:

```
*.ex, *.exs, *.eex, *.leex, *.lock
```

Elixir and Euphoria share the \*.ex file extension. If the filetype is specifically set as Euphoria with the `g:filetype_euphoria` variable, or the file is determined to be Euphoria based on keywords in the file, then the filetype will be set as Euphoria. Otherwise, the filetype will default to Elixir.

## FLEXWIKI

`flexwiki.vim` `ft-flexwiki-syntax`

FlexWiki is an ASP.NET-based wiki package which used to be available at <http://www.flexwiki.com>

**NOTE:** This site currently doesn't work, on Wikipedia is mentioned that development stopped in 2009.

Syntax highlighting is available for the most common elements of FlexWiki syntax. The associated ftplugin script sets some buffer-local options to make editing FlexWiki pages more convenient. FlexWiki considers a newline as the start of a new paragraph, so the ftplugin sets `'tw'=0` (unlimited line length), `'wrap'` (wrap long lines instead of using horizontal scrolling), `'linebreak'` (to wrap at a character in `'breakat'` instead of at the last char on screen), and so on. It also includes some keymaps that are disabled by default.

If you want to enable the keymaps that make "j" and "k" and the cursor keys move up and down by display lines, add this to your .vimrc:

```
:let flexwiki_maps = 1
```

## FORM

`form.vim` `ft-form-syntax`

The coloring scheme for syntax elements in the FORM file uses the default modes Conditional, Number, Statement, Comment, PreProc, Type, and String, following the language specifications in 'Symbolic Manipulation with FORM' by J.A.M. Vermaseren, CAN, Netherlands, 1991.

If you want to include your own changes to the default colors, you have to redefine the following syntax groups:

- formConditional
- formNumber
- formStatement
- formHeaderStatement
- formComment
- formPreProc
- formDirective
- formType
- formString

**Note** that the form.vim syntax file implements FORM preprocessor commands and directives per default in the same syntax group.

A predefined enhanced color mode for FORM is available to distinguish between header statements and statements in the body of a FORM program. To activate this mode define the following variable in your vimrc file

```
:let form_enhanced_color=1
```

The enhanced mode also takes advantage of additional color features for a dark gvim display. Here, statements are colored LightYellow instead of Yellow, and conditionals are LightBlue for better distinction.

Both Visual Basic and FORM use the extension ".frm". To detect which one should be used, Vim checks for the string "VB\_Name" in the first five lines of the file. If it is found, filetype will be "vb", otherwise "form".

If the automatic detection doesn't work for you or you only edit, for example, FORM files, use this in your startup vimrc:

```
:let filetype_frm = "form"
```

## **FORTH**

[forth.vim](#) [ft-forth-syntax](#)

Files matching "\*.f" could be Fortran or Forth and those matching "\*.fs" could be F# or Forth. If the automatic detection doesn't work for you, or you don't edit F# or Fortran at all, use this in your startup vimrc:

```
:let filetype_f = "forth"
:let filetype_fs = "forth"
```

## **FORTRAN**

[fortran.vim](#) [ft-fortran-syntax](#)

### **Default highlighting and dialect**

Vim highlights according to Fortran 2023 (the most recent standard). This choice should be appropriate for most users most of the time because Fortran 2023 is almost a superset of previous versions (Fortran 2018, 2008, 2003, 95, 90, 77, and 66). A few legacy constructs deleted or declared obsolescent, respectively, in recent Fortran standards are highlighted as errors and todo items.

The syntax script no longer supports Fortran dialects. The variable `fortran_dialect` is now silently ignored. Since computers are much faster now, the variable `fortran_more_precise` is no longer needed and is silently ignored.

### Fortran source code form

Fortran code can be in either fixed or free source form. **Note** that the syntax highlighting will not be correct if the form is incorrectly set.

When you create a new Fortran file, the syntax script assumes fixed source form. If you always use free source form, then

```
:let fortran_free_source=1
```

in your `.vimrc` prior to the `:syntax on` command. If you always use fixed source form, then

```
:let fortran_fixed_source=1
```

in your `.vimrc` prior to the `:syntax on` command.

If the form of the source code depends, in a non-standard way, upon the file extension, then it is most convenient to set `fortran_free_source` in a `ftplugin` file. For more information on `ftplugin` files, see [ftplugin](#). **Note** that this will work only if the "filetype plugin indent on" command precedes the "syntax on" command in your `.vimrc` file.

When you edit an existing Fortran file, the syntax script will assume free source form if the `fortran_free_source` variable has been set, and assumes fixed source form if the `fortran_fixed_source` variable has been set. Suppose neither of these variables have been set. In that case, the syntax script attempts to determine which source form has been used by examining the file extension using conventions common to the `ifort`, `gfortran`, Cray, NAG, and PathScale compilers (`.f`, `.for`, `.f77` for fixed-source, `.f90`, `.f95`, `.f03`, `.f08` for free-source). No default is used for the `.fpp` and `.ftn` file extensions because different compilers treat them differently. If none of this works, then the script examines the first five columns of the first 500 lines of your file. If no signs of free source form are detected, then the file is assumed to be in fixed source form. The algorithm should work in the vast majority of cases. In some cases, such as a file that begins with 500 or more full-line comments, the script may incorrectly decide that the code is in fixed form. If that happens, just add a non-comment statement beginning anywhere in the first five columns of the first twenty-five lines, save (`:w`), and then reload (`:e!`) the file.

### Vendor extensions

Fixed-form Fortran requires a maximum line length of 72 characters but the script allows a maximum line length of 80 characters as do all compilers created in the last three decades. An even longer line length of 132 characters is allowed if you set the variable `fortran_extended_line_length` with a command such as

```
:let fortran_extended_line_length=1
```

placed prior to the `:syntax on` command.

If you want additional highlighting of the CUDA Fortran extensions, you should set the variable `fortran_CUDA` with a command such as

```
:let fortran_CUDA=1
```

placed prior to the `:syntax on` command.

To activate recognition of some common, non-standard, vendor-supplied intrinsics, you should set the variable `fortran_vendor_intrinsics` with a command such as

```
:let fortran_vendor_intrinsics=1
```

placed prior to the `:syntax` on command.

### Tabs in Fortran files

Tabs are not recognized by the Fortran standards. Tabs are not a good idea in fixed format Fortran source code which requires fixed column boundaries.

Therefore, tabs are marked as errors. Nevertheless, some programmers like using tabs. If your Fortran files contain tabs, then you should set the variable `fortran_have_tabs` in your `.vimrc` with a command such as

```
:let fortran_have_tabs=1
```

placed prior to the `:syntax` on command. Unfortunately, the use of tabs will mean that the syntax file will not be able to detect incorrect margins.

### Syntax folding of Fortran files

Vim will fold your file using `foldmethod=syntax`, if you set the variable `fortran_fold` in your `.vimrc` with a command such as

```
:let fortran_fold=1
```

to instruct the syntax script to define fold regions for program units, that is main programs starting with a program statement, subroutines, function subprograms, modules, submodules, blocks of comment lines, and block data units. Block, interface, associate, critical, type definition, and change team constructs will also be folded. If you also set the variable `fortran_fold_conditionals` with a command such as

```
:let fortran_fold_conditionals=1
```

then fold regions will also be defined for do loops, if blocks, select case, select type, and select rank constructs. **Note** that defining fold regions can be slow for large files.

The `syntax/fortran.vim` script contains embedded comments that tell you how to comment and/or uncomment some lines to (a) activate recognition of some non-standard, vendor-supplied intrinsics and (b) to prevent features deleted or declared obsolescent in the 2008 standard from being highlighted as todo items.

### Limitations

Parenthesis checking does not catch too few closing parentheses. Hollerith strings are not recognized. Some keywords may be highlighted incorrectly because Fortran90 has no reserved words.

For further information related to Fortran, see [ft-fortran-indent](#) and [ft-fortran-plugin](#).

### **FREEBASIC**

[freebasic.vim](#) [ft-freebasic-syntax](#)

FreeBASIC files will be highlighted differently for each of the four available dialects, "fb", "qb", "fblite" and "deprecated". See [ft-freebasic-plugin](#) for how to select the correct dialect.

Highlighting is further configurable via the following variables.

Variable	Highlight
<code>freebasic_no_comment_fold</code>	disable multiline comment folding
<code>freebasic_operators</code>	non-alpha operators
<code>freebasic_space_errors</code>	trailing white space and spaces before a <Tab>
<code>freebasic_type_suffixes</code>	QuickBASIC style type suffixes

## FVWM CONFIGURATION FILES

`fvwm.vim` `ft-fvwm-syntax`

In order for Vim to recognize Fvwm configuration files that do not match the patterns `fvwmrc` or `fvwm2rc`, you must put additional patterns appropriate to your system in your `myfiletypes.vim` file. For these patterns, you must set the variable "b:fvwm\_version" to the major version number of Fvwm, and the **'filetype'** option to `fvwm`.

For example, to make Vim identify all files in `/etc/X11/fvwm2/` as Fvwm2 configuration files, add the following:

```
:au! BufNewFile,BufRead /etc/X11/fvwm2/* let b:fvwm_version = 2 |
\ set filetype=fvwm
```

## GSP

`gsp.vim` `ft-gsp-syntax`

The default coloring style for GSP pages is defined by `html.vim`, and the coloring for java code (within java tags or inline between backticks) is defined by `java.vim`. The following HTML groups defined in `html.vim` are redefined to incorporate and highlight inline java code:

```
htmlString
htmlValue
htmlEndTag
htmlTag
htmlTagN
```

Highlighting should look fine most of the places where you'd see inline java code, but in some special cases it may not. To add another HTML group where you will have inline java code where it does not highlight correctly, just copy the line you want from `html.vim` and add `gspJava` to the contains clause.

The backticks for inline java are highlighted according to the `htmlError` group to make them easier to see.

## GROFF

`groff.vim` `ft-groff-syntax`

The groff syntax file is a wrapper for `nroff.vim`, see the notes under that heading for examples of use and configuration. The purpose of this wrapper is to set up groff syntax extensions by setting the filetype from a `modeline` or in a personal filetype definitions file (see `filetype.txt`).

## HASKELL

`haskell.vim` `lhaskell.vim` `ft-haskell-syntax`

The Haskell syntax files support plain Haskell code as well as literate Haskell code, the latter in both Bird style and TeX style. The Haskell syntax highlighting will also highlight C preprocessor directives.

If you want to highlight delimiter characters (useful if you have a light-coloured background), add to your `.vimrc`:

```
:let hs_highlight_delimiters = 1
```

To treat `True` and `False` as keywords as opposed to ordinary identifiers, add:

```
:let hs_highlight_boolean = 1
```

To also treat the names of primitive types as keywords:

```
:let hs_highlight_types = 1
```

And to treat the names of even more relatively common types as keywords:

```
:let hs_highlight_more_types = 1
```

If you want to highlight the names of debugging functions, put in your `.vimrc`:

```
:let hs_highlight_debug = 1
```

The Haskell syntax highlighting also highlights C preprocessor directives, and flags lines that start with `#` but are not valid directives as erroneous. This interferes with Haskell's syntax for operators, as they may start with `#`. If you want to highlight those as operators as opposed to errors, put in your `.vimrc`:

```
:let hs_allow_hash_operator = 1
```

The syntax highlighting for literate Haskell code will try to automatically guess whether your literate Haskell code contains TeX markup or not, and correspondingly highlight TeX constructs or nothing at all. You can override this globally by putting in your `.vimrc`

```
:let lhs_markup = none
```

for no highlighting at all, or

```
:let lhs_markup = tex
```

to force the highlighting to always try to highlight TeX markup. For more flexibility, you may also use buffer local versions of this variable, so e.g.

```
:let b:lhs_markup = tex
```

will force TeX highlighting for a particular buffer. It has to be set before turning syntax highlighting on for the buffer or loading a file.

## HTML

`html.vim` `ft-html-syntax`

The coloring scheme for tags in the HTML file works as follows.

The `<>` of opening tags are colored differently than the `</>` of a closing tag. This is on purpose! For opening tags the 'Function' color is used, while for closing tags the 'Identifier' color is used (See `syntax.vim` to check how those are defined for you)

Known tag names are colored the same way as statements in C. Unknown tag

names are colored with the same color as the `<>` or `</>` respectively which makes it easy to spot errors

**Note** that the same is true for argument (or attribute) names. Known attribute names are colored differently than unknown ones.

Some HTML tags are used to change the rendering of text. The following tags are recognized by the `html.vim` syntax coloring file and change the way normal text is shown: `<B>` `<I>` `<U>` `<EM>` `<STRONG>` (`<EM>` is used as an alias for `<I>`, while `<STRONG>` as an alias for `<B>`), `<H1>` - `<H6>`, `<HEAD>`, `<TITLE>` and `<A>`, but only if used as a link (that is, it must include a href as in `<A href="somefile.html">`).

If you want to change how such text is rendered, you must redefine the following syntax groups:

- `htmlBold`
- `htmlBoldUnderline`
- `htmlBoldUnderlineItalic`
- `htmlUnderline`
- `htmlUnderlineItalic`
- `htmlItalic`
- `htmlTitle` for titles
- `htmlH1` - `htmlH6` for headings

To make this redefinition work you must redefine them all with the exception of the last two (`htmlTitle` and `htmlH[1-6]`, which are optional) and define the following variable in your `vimrc` (this is due to the order in which the files are read during initialization)

```
:let html_my_rendering=1
```

If you'd like to see an example download `mysyntax.vim` at <http://www.fleiner.com/vim/download.html>

You can also disable this rendering by adding the following line to your `vimrc` file:

```
:let html_no_rendering=1
```

By default Vim synchronises the syntax to 250 lines before the first displayed line. This can be configured using:

```
:let html_minlines = 500
```

HTML comments are rather special (see an HTML reference document for the details), and the syntax coloring scheme will highlight all errors. However, if you prefer to use the wrong style (starts with `<!--` and ends with `-->`) you can define

```
:let html_wrong_comments=1
```

JavaScript and Visual Basic embedded inside HTML documents are highlighted as 'Special' with statements, comments, strings and so on colored as in standard programming languages. **Note** that only JavaScript and Visual Basic are currently supported, no other scripting language has been added yet.

Embedded and inlined cascading style sheets (CSS) are highlighted too.

There are several html preprocessor languages out there. `html.vim` has been written such that it should be trivial to include it. To do so add the following two lines to the syntax coloring file for that language (the example comes from the `asp.vim` file):

```
runtime! syntax/html.vim
syn cluster htmlPreproc add=asp
```

Now you just need to make sure that you add all regions that contain the preprocessor language to the cluster `htmlPreproc`.

The HTML syntax file provides syntax [folding](#) (see `:syn-fold`) between start and end tags. This can be turned on by

```
:let g:html_syntax_folding = 1
:set foldmethod=syntax
```

**Note:** Syntax folding might slow down syntax highlighting significantly, especially for large files.

HTML/OS (BY AESTIVA) [htmllos.vim](#) [ft-htmllos-syntax](#)

The coloring scheme for HTML/OS works as follows:

Functions and variable names are the same color by default, because VIM doesn't specify different colors for Functions and Identifiers. To change this (which is recommended if you want function names to be recognizable in a different color) you need to add the following line to either your `~/.vimrc`:

```
:hi Function term=underline cterm=bold ctermfg=LightGray
```

Of course, the `ctermfg` can be a different color if you choose.

Another issue that HTML/OS runs into is that there is no special filetype to signify that it is a file with HTML/OS coding. You can change this by opening a file and turning on HTML/OS syntax by doing the following:

```
:set syntax=htmllos
```

Lastly, it should be noted that the opening and closing characters to begin a block of HTML/OS code can either be `<<` or `[[` and `>>` or `]]`, respectively.

**IA64** [ia64.vim](#) [intel-itanium](#) [ft-ia64-syntax](#)

Highlighting for the Intel Itanium 64 assembly language. See [asm.vim](#) for how to recognize this filetype.

To have `*.inc` files be recognized as IA64, add this to your `.vimrc` file:

```
:let g:filetype_inc = "ia64"
```

**INFORM** [inform.vim](#) [ft-inform-syntax](#)

Inform highlighting includes symbols provided by the Inform Library, as most programs make extensive use of it. If do not wish Library symbols to be highlighted add this to your vim startup:

```
:let inform_highlight_simple=1
```

By default it is assumed that Inform programs are Z-machine targeted, and highlights Z-machine assembly language symbols appropriately. If you intend your program to be targeted to a Glulx/Glk environment you need to add this to your startup sequence:

```
:let inform_highlight_glulx=1
```

This will highlight Glulx opcodes instead, and also adds glk() to the set of highlighted system functions.

The Inform compiler will flag certain obsolete keywords as errors when it encounters them. These keywords are normally highlighted as errors by Vim. To prevent such error highlighting, you must add this to your startup sequence:

```
:let inform_suppress_obsolete=1
```

By default, the language features highlighted conform to Compiler version 6.30 and Library version 6.11. If you are using an older Inform development environment, you may wish to add this to your startup sequence:

```
:let inform_highlight_old=1
```

## IDL

[idl.vim](#) [idl-syntax](#)

IDL (Interface Definition Language) files are used to define RPC calls. In Microsoft land, this is also used for defining COM interfaces and calls.

IDL's structure is simple enough to permit a full grammar based approach to rather than using a few heuristics. The result is large and somewhat repetitive but seems to work.

There are some Microsoft extensions to idl files that are here. Some of them are disabled by defining `idl_no_ms_extensions`.

The more complex of the extensions are disabled by defining `idl_no_extensions`.

Variable	Effect
<code>idl_no_ms_extensions</code>	Disable some of the Microsoft specific extensions
<code>idl_no_extensions</code>	Disable complex extensions
<code>idlsyntax_showerror</code>	Show IDL errors (can be rather intrusive, but quite helpful)
<code>idlsyntax_showerror_soft</code>	Use softer colours by default for errors

## JAVA

[java.vim](#) [ft-java-syntax](#)

The `java.vim` syntax highlighting file offers several options.

In Java 1.0.2, it was never possible to have braces inside parens, so this was flagged as an error. Since Java 1.1, this is possible (with anonymous classes); and, therefore, is no longer marked as an error. If you prefer the old way, put the following line into your Vim startup file:

```
:let g:java_mark_braces_in_parens_as_errors = 1
```

All (exported) public types declared in ``java.lang`` are always automatically imported and available as simple names. To highlight them, use:

```
:let g:java_highlight_java_lang_ids = 1
```

You can also highlight types of most standard Java packages if you download the `javaid.vim` script at <http://www.fleiner.com/vim/download.html>. If you prefer to only highlight types of a certain package, say ``java.io``, use the following:

```
:let g:java_highlight_java_io = 1
```

Check the `javaid.vim` file for a list of all the packages that are supported.

Headers of indented function declarations can be highlighted (along with parts of lambda expressions and method reference expressions), but it depends on how you write Java code. Two formats are recognized:

1) If you write function declarations that are consistently indented by either a tab, or a space . . . or eight space character(s), you may want to set one of

```
:let g:java_highlight_functions = "indent"
:let g:java_highlight_functions = "indent1"
:let g:java_highlight_functions = "indent2"
:let g:java_highlight_functions = "indent3"
:let g:java_highlight_functions = "indent4"
:let g:java_highlight_functions = "indent5"
:let g:java_highlight_functions = "indent6"
:let g:java_highlight_functions = "indent7"
:let g:java_highlight_functions = "indent8"
```

**Note** that in terms of `'shiftwidth'`, this is the leftmost step of indentation.

2) However, if you follow the Java guidelines about how functions and types are supposed to be named (with respect to upper- and lowercase) and there is any amount of indentation, you may want to set

```
:let g:java_highlight_functions = "style"
```

In addition, you can combine any value of `"g:java_highlight_functions"` with

```
:let g:java_highlight_signature = 1
```

to have the name of a function with its parameter list parens distinctly highlighted from its type parameters, return type, and formal parameters; and to have the parameter list parens of a lambda expression with its arrow distinctly highlighted from its formal parameters or identifiers.

If neither setting does work for you, but you would still want headers of function declarations to be highlighted, modify the current syntax definitions or compose new ones.

Higher-order function types can be hard to parse by eye, so uniformly toning down some of their components may be of value. Provided that such type names

conform to the Java naming guidelines, you may arrange it with

```
:let g:java_highlight_generics = 1
```

In Java 1.1, the functions `System.out.println()` and `System.err.println()` should only be used for debugging. Consider adding the following definition in your startup file:

```
:let g:java_highlight_debug = 1
```

to have the bulk of those statements colored as

```
*Debug debugging statements,
```

and to make some of their own items further grouped and linked:

```
*Special as DebugSpecial,
*String as DebugString,
*Boolean as DebugBoolean,
*Type as DebugType,
```

which are used for special characters appearing in strings, strings proper, boolean literals, and special instance references (`super`, `this`, `null`), respectively.

Javadoc is a program that takes special comments out of Java program files and creates HTML pages. The standard configuration will highlight this HTML code similarly to HTML files (see [html.vim](#)). You can even add JavaScript and CSS inside this code (see below). The HTML rendering and the Markdown rendering diverge as follows:

1. The first sentence (all characters up to the first period `.`, which is followed by a whitespace character or a line terminator, or up to the first block tag, e.g. `@param`, `@return`) is colored as  

```
*SpecialComment special comments.
```
2. The text is colored as  

```
*Comment comments.
```
3. HTML comments are colored as  

```
*Special special symbols.
```
4. The standard Javadoc tags (`@code`, `@see`, etc.) are colored as  

```
*Special special symbols
```

and some of their arguments are colored as  

```
*Function function names.
```

To turn this feature off for both HTML and Markdown, add the following line to your startup file:

```
:let g:java_ignore_javadoc = 1
```

Alternatively, only suppress HTML comments or Markdown comments:

```
:let g:java_ignore_html = 1
:let g:java_ignore_markdown = 1
```

See [ft-java-plugin](#) for additional support available for Markdown comments.

If you use the special Javadoc comment highlighting described above, you can also turn on special highlighting for JavaScript, Visual Basic scripts, and embedded CSS (stylesheets). This only makes sense if any of these languages actually appear in Javadoc comments. The variables to use are

```
:let g:java_javascript = 1
:let g:java_css = 1
:let g:java_vb = 1
```

**Note** that these three variables are maintained in the HTML syntax file.

Numbers and strings can be recognized in non-Javadoc comments with

```
:let g:java_comment_strings = 1
```

When `'foldmethod'` is set to "syntax", blocks of code and multi-line comments will be folded. No text is usually written in the first line of a multi-line comment, making folded contents of Javadoc comments less informative with the default `'foldtext'` value; you may opt for showing the contents of a second line for any comments written in this way, and showing the contents of a first line otherwise, with

```
:let g:java_foldtext_show_first_or_second_line = 1
```

Trailing whitespace characters or a run of space characters before a tab character can be marked as an error with

```
:let g:java_space_errors = 1
```

but either kind of an error can be suppressed by also defining one of

```
:let g:java_no_trail_space_error = 1
```

```
:let g:java_no_tab_space_error = 1
```

In order to highlight nested parens with different colors, define colors for `'javaParen'`, `'javaParen1'`, and `'javaParen2'`. For example,

```
:hi link javaParen Comment
```

or

```
:hi javaParen ctermfg=blue guifg=#0000ff
```

Certain modifiers are incompatible with each other, e.g. `'abstract'` and `'final'`:

```
:syn list javaConceptKind
```

and can be differently highlighted as a group than other modifiers with

```
:hi link javaConceptKind NonText
```

If you notice highlighting errors while scrolling backwards, which are fixed when redrawing with **CTRL-L**, try setting the "g:java\_minlines" variable to a larger number:

```
:let g:java_minlines = 50
```

This will make the syntax synchronization start 50 lines before the first displayed line. The default value is 10. The disadvantage of using a larger number is that redrawing can become slow.

Significant changes to the Java platform are gradually introduced in the form of JDK Enhancement Proposals (JEPs) that can be implemented for a release and offered as its preview features. It may take several JEPs and a few release cycles for such a feature to become either integrated into the platform or withdrawn from this effort. To cater for early adopters, there is optional support in Vim for syntax related preview features that are implemented. You can request it by specifying a list of preview feature numbers as follows:

```
:let g:java_syntax_previews = [455, 476]
```

The supported JEP numbers are to be drawn from this table:

```
`430`: String Templates [JDK 21]
```

```
`455`: Primitive types in Patterns, instanceof, and switch
```

```
`476`: Module Import Declarations
```

**Note** that as soon as the particular preview feature will have been integrated into the Java platform, its entry will be removed from the table and related optionality will be discontinued.

**JSON** `json.vim` `ft-json-syntax` `g:vim_json_conceal`  
`g:vim_json_warnings`

The json syntax file provides syntax highlighting with conceal support by default. To disable concealment:

```
let g:vim_json_conceal = 0
```

To disable syntax highlighting of errors:

```
let g:vim_json_warnings = 0
```

**JQ** `jq.vim` `jq_quote_highlight` `ft-jq-syntax`

To disable numbers having their own color add the following to your vimrc:

```
hi link jqNumber Normal
```

If you want quotes to have different highlighting than strings

```
let g:jq_quote_highlight = 1
```

**KCONFIG** `ft-kconfig-syntax`

Kconfig syntax highlighting language. For syntax syncing, you can configure the following variable (default: 50):

```
let kconfig_minlines = 50
```

To configure a bit more (heavier) highlighting, set the following variable:

```
let kconfig_syntax_heavy = 1
```

**LACE** `lace.vim` `ft-lace-syntax`

Lace (Language for Assembly of Classes in Eiffel) is case insensitive, but the style guide lines are not. If you prefer case insensitive highlighting, just define the vim variable 'lace\_case\_insensitive' in your startup file:

```
:let lace_case_insensitive=1
```

**LF (LFRC)** `lf.vim` `ft-lf-syntax` `g:lf_shell_syntax`  
`b:lf_shell_syntax`

For the lf file manager configuration files (lfrc) the shell commands syntax highlighting can be changed globally and per buffer by setting a different **'include'** command search pattern using these variables:

```
let g:lf_shell_syntax = "syntax/dosbatch.vim"
let b:lf_shell_syntax = "syntax/zsh.vim"
```

These variables are unset by default.

The default **'include'** command search pattern is 'syntax/sh.vim'.

## LEX

`lex.vim` `ft-lex-syntax`

Lex uses brute-force synchronizing as the "`^%$`" section delimiter gives no clue as to what section follows. Consequently, the value for

```
:syn sync minlines=300
```

may be changed by the user if s/he is experiencing synchronization difficulties (such as may happen with large lex files).

## LIFELINES

`lifelines.vim` `ft-lifelines-syntax`

To highlight deprecated functions as errors, add in your `.vimrc`:

```
:let g:lifelines_deprecated = 1
```

## LISP

`lisp.vim` `ft-lisp-syntax`

The lisp syntax highlighting provides two options:

```
g:lisp_instring : If it exists, then "(...)" strings are highlighted as if the contents of the string were lisp. Useful for AutoLisp.
g:lisp_rainbow : If it exists and is nonzero, then differing levels of parenthesization will receive different highlighting.
```

The `g:lisp_rainbow` option provides 10 levels of individual colorization for the parentheses and backquoted parentheses. Because of the quantity of colorization levels, unlike non-rainbow highlighting, the rainbow mode specifies its highlighting using `ctermfg` and `guifg`, thereby bypassing the usual color scheme control using standard highlighting groups. The actual highlighting used depends on the dark/bright setting (see `'bg'`).

## LITE

`lite.vim` `ft-lite-syntax`

There are two options for the lite syntax highlighting.

If you like SQL syntax highlighting inside Strings, use this:

```
:let lite_sql_query = 1
```

For syncing, `minlines` defaults to 100. If you prefer another value, you can set "`lite_minlines`" to the value you desire. Example:

```
:let lite_minlines = 200
```

## LPC

`lpc.vim` `ft-lpc-syntax`

LPC stands for a simple, memory-efficient language: Lars Pensjö C. The file name of LPC is usually `*.c`. Recognizing these files as LPC would bother users writing only C programs. If you want to use LPC syntax in Vim, you

should set a variable in your .vimrc file:

```
:let lpc_syntax_for_c = 1
```

If it doesn't work properly for some particular C or LPC files, use a modeline. For a LPC file:

```
// vim:set ft=lpc:
```

For a C file that is recognized as LPC:

```
// vim:set ft=c:
```

If you don't want to set the variable, use the modeline in EVERY LPC file.

There are several implementations for LPC, we intend to support most widely used ones. Here the default LPC syntax is for MudOS series, for MudOS v22 and before, you should turn off the sensible modifiers, and this will also assert the new efuns after v22 to be invalid, don't set this variable when you are using the latest version of MudOS:

```
:let lpc_pre_v22 = 1
```

For LpMud 3.2 series of LPC:

```
:let lpc_compat_32 = 1
```

For LPC4 series of LPC:

```
:let lpc_use_lpc4_syntax = 1
```

For uLPC series of LPC:

uLPC has been developed to Pike, so you should use Pike syntax instead, and the name of your source file should be \*.pike

## LUA

lua.vim ft-lua-syntax

The Lua syntax file can be used for versions 4.0, 5.0+. You can select one of these versions using the global variables `g:lua_version` and `g:lua_subversion`.

## MAIL

mail.vim ft-mail.vim

Vim highlights all the standard elements of an email (headers, signatures, quoted text and URLs / email addresses). In keeping with standard conventions, signatures begin in a line containing only "--" followed optionally by whitespaces and end with a newline.

Vim treats lines beginning with ']', '}', '|', '>' or a word followed by '>' as quoted text. However Vim highlights headers and signatures in quoted text only if the text is quoted with '>' (optionally followed by one space).

By default mail.vim synchronises syntax to 100 lines before the first displayed line. If you have a slow machine, and generally deal with emails with short headers, you can change this to a smaller value:

```
:let mail_minlines = 30
```

## MAKE

make.vim ft-make-syntax

In makefiles, commands are usually highlighted to make it easy for you to spot errors. However, this may be too much coloring for you. You can turn this feature off by using:

```
:let make_no_commands = 1
```

Comments are also highlighted by default. You can turn this off by using:

```
:let make_no_comments = 1
```

Microsoft Makefile handles variable expansion and comments differently (backslashes are not used for escape). If you see any wrong highlights because of this, you can try this:

```
:let make_microsoft = 1
```

## MAPLE

maple.vim ft-maple-syntax

Maple V, by Waterloo Maple Inc, supports symbolic algebra. The language supports many packages of functions which are selectively loaded by the user. The standard set of packages' functions as supplied in Maple V release 4 may be highlighted at the user's discretion. Users may place in their .vimrc file:

```
:let mvpkg_all= 1
```

to get all package functions highlighted, or users may select any subset by choosing a variable/package from the table below and setting that variable to 1, also in their .vimrc file (prior to sourcing \$VIMRUNTIME/syntax/syntax.vim).

Table of Maple V Package Function Selectors

mv_DEtools	mv_genfunc	mv_networks	mv_process
mv_Galois	mv_geometry	mv_numapprox	mv_simplex
mv_GaussInt	mv_grobner	mv_numtheory	mv_stats
mv_LREtools	mv_group	mv_orthopoly	mv_student
mv_combinat	mv_inttrans	mv_padic	mv_sumtools
mv_combstruct	mv_liesymm	mv_plots	mv_tensor
mv_diffforms	mv_linalg	mv_plottools	mv_totorder
mv_finance	mv_logic	mv_powseries	

## MARKDOWN

ft-markdown-syntax g:markdown\_minlines  
g:markdown\_fenced\_languages g:markdown\_syntax\_conceal

If you have long regions there might be wrong highlighting. At the cost of slowing down displaying, you can have the engine look further back to sync on the start of a region, for example 500 lines (default is 50):

```
:let g:markdown_minlines = 500
```

If you want to enable fenced code block syntax highlighting in your markdown documents you can enable like this:

```
:let g:markdown_fenced_languages = ['html', 'python', 'bash=sh']
```

To disable markdown syntax concealing add the following to your vimrc:

```
:let g:markdown_syntax_conceal = 0
```

**MATHEMATICA** `mma.vim` `ft-mma-syntax` `ft-mathematica-syntax`

Empty \*.m files will automatically be presumed to be Matlab files unless you have the following in your .vimrc:

```
let filetype_m = "mma"
```

**MEDIAWIKI** `ft-mediawiki-syntax`

By default, syntax highlighting includes basic HTML tags like style and headers `html.vim`. For strict Mediawiki syntax highlighting:

```
let g:html_no_rendering = 1
```

If HTML highlighting is desired, terminal-based text formatting such as bold and italic is possible by:

```
let g:html_style_rendering = 1
```

**MODULA2** `modula2.vim` `ft-modula2-syntax`

Vim will recognise comments with dialect tags to automatically select a given dialect.

The syntax for a dialect tag comment is:

```
taggedComment :=
 '(*!' dialectTag '*)'
;

dialectTag :=
 m2pim | m2iso | m2r10
;

reserved words
 m2pim = 'm2pim', m2iso = 'm2iso', m2r10 = 'm2r10'
```

A dialect tag comment is recognised by Vim if it occurs within the first 200

lines of the source file. Only the very first such comment is recognised, any additional dialect tag comments are ignored.

Example:

```
DEFINITION MODULE FooLib; (*!m2pim*)
...
```

Variable `g:modula2_default_dialect` sets the default Modula-2 dialect when the dialect cannot be determined from the contents of the Modula-2 file: if defined and set to `'m2pim'`, the default dialect is PIM.

Example:

```
let g:modula2_default_dialect = 'm2pim'
```

Highlighting is further configurable for each dialect via the following variables.

Variable	Highlight
<code>modula2_iso_allow_lowline</code>	allow low line in identifiers
<code>modula2_iso_disallow_octals</code>	disallow octal integer literals
<code>modula2_iso_disallow_synonyms</code>	disallow "@", "&" and "~" synonyms
<code>modula2_pim_allow_lowline</code>	allow low line in identifiers
<code>modula2_pim_disallow_octals</code>	disallow octal integer literals
<code>modula2_pim_disallow_synonyms</code>	disallow "&" and "~" synonyms
<code>modula2_r10_allow_lowline</code>	allow low line in identifiers

**MOO** `moo.vim` `ft-moo-syntax`

If you use C-style comments inside expressions and find it mangles your highlighting, you may want to use extended (slow!) matches for C-style comments:

```
:let moo_extended_cstyle_comments = 1
```

To disable highlighting of pronoun substitution patterns inside strings:

```
:let moo_no_pronoun_sub = 1
```

To disable highlighting of the regular expression operator `'%|'`, and matching `'%('` and `'%)'` inside strings:

```
:let moo_no_regexp = 1
```

Unmatched double quotes can be recognized and highlighted as errors:

```
:let moo_unmatched_quotes = 1
```

To highlight builtin properties (`.name`, `.location`, `.programmer` etc.):

```
:let moo_builtin_properties = 1
```

Unknown builtin functions can be recognized and highlighted as errors. If you use this option, add your own extensions to the `mooKnownBuiltinFunction` group. To enable this option:

```
:let moo_unknown_builtin_functions = 1
```

An example of adding `sprintf()` to the list of known builtin functions:

```
:syn keyword mooKnownBuiltinFunction sprintf contained
```

## MSQL

[msql.vim](#) [ft-msql-syntax](#)

There are two options for the msql syntax highlighting.

If you like SQL syntax highlighting inside Strings, use this:

```
:let msql_sql_query = 1
```

For syncing, `minlines` defaults to 100. If you prefer another value, you can set `"msql_minlines"` to the value you desire. Example:

```
:let msql_minlines = 200
```

## NEOMUTT

[neomutt.vim](#) [ft-neomuttrc-syntax](#)  
[ft-neomuttlog-syntax](#)

To disable the default NeoMutt log colors:

```
:let g:neolog_disable_default_colors = 1
```

## N1QL

[n1ql.vim](#) [ft-n1ql-syntax](#)

N1QL is a SQL-like declarative language for manipulating JSON documents in Couchbase Server databases.

Vim syntax highlights N1QL statements, keywords, operators, types, comments, and special values. Vim ignores syntactical elements specific to SQL or its many dialects, like `COLUMN` or `CHAR`, that don't exist in N1QL.

## NCF

[ncf.vim](#) [ft-ncf-syntax](#)

There is one option for NCF syntax highlighting.

If you want to have unrecognized (by `ncf.vim`) statements highlighted as errors, use this:

```
:let ncf_highlight_unknowns = 1
```

If you don't want to highlight these errors, leave it unset.

## NROFF

nroff.vim ft-nroff-syntax

The nroff syntax file works with AT&T n/troff out of the box. You need to activate the GNU groff extra features included in the syntax file before you can use them.

For example, Linux and BSD distributions use groff as their default text processing package. In order to activate the extra syntax highlighting features for groff, arrange for files to be recognized as groff (see [ft-groff-syntax](#) ) or add the following option to your start-up files:

```
:let nroff_is_groff = 1
```

Groff is different from the old AT&T n/troff that you may still find in Solaris. Groff macro and request names can be longer than 2 characters and there are extensions to the language primitives. For example, in AT&T troff you access the year as a 2-digit number with the request `\(yr`. In groff you can use the same request, recognized for compatibility, or you can use groff's native syntax, `\[yr]`. Furthermore, you can use a 4-digit year directly: `\[year]`. Macro requests can be longer than 2 characters, for example, GNU mm accepts the requests `".VERBON"` and `".VERBOFF"` for creating verbatim environments.

In order to obtain the best formatted output g/troff can give you, you should follow a few simple rules about spacing and punctuation.

1. Do not leave empty spaces at the end of lines.
2. Leave one space and one space only after an end-of-sentence period, exclamation mark, etc.
3. For reasons stated below, it is best to follow all period marks with a carriage return.

The reason behind these unusual tips is that g/n/troff have a line breaking algorithm that can be easily upset if you don't follow the rules given above.

Unlike TeX, troff fills text line-by-line, not paragraph-by-paragraph and, furthermore, it does not have a concept of glue or stretch, all horizontal and vertical space input will be output as is.

Therefore, you should be careful about not using more space between sentences than you intend to have in your final document. For this reason, the common practice is to insert a carriage return immediately after all punctuation marks. If you want to have "even" text in your final processed output, you need to maintain regular spacing in the input text. To mark both trailing spaces and two or more spaces after a punctuation as an error, use:

```
:let nroff_space_errors = 1
```

Another technique to detect extra spacing and other errors that will interfere with the correct typesetting of your file, is to define an eye-catching

highlighting definition for the syntax groups "nroffDefinition" and "nroffDefSpecial" in your configuration files. For example:

```
hi def nroffDefinition term=italic cterm=italic gui=reverse
hi def nroffDefSpecial term=italic,bold cterm=italic,bold
\ gui=reverse,bold
```

If you want to navigate preprocessor entries in your source file as easily as with section markers, you can activate the following option in your .vimrc file:

```
let b:preprocs_as_sections = 1
```

As well, the syntax file adds an extra paragraph marker for the extended paragraph macro (.XP) in the ms package.

Finally, there is a `groff.vim` syntax file that can be used for enabling groff syntax highlighting either on a file basis or globally by default.

## OCAML

`ocaml.vim` `ft-ocaml-syntax`

The OCaml syntax file handles files having the following prefixes: .ml, .mli, .mll and .mly. By setting the following variable

```
:let ocaml_revised = 1
```

you can switch from standard OCaml-syntax to revised syntax as supported by the camlp4 preprocessor. Setting the variable

```
:let ocaml_noend_error = 1
```

prevents highlighting of "end" as error, which is useful when sources contain very long structures that Vim does not synchronize anymore.

## PANDOC

`ft-pandoc-syntax`

By default, markdown files will be detected as filetype "markdown". Alternatively, you may want them to be detected as filetype "pandoc" instead. To do so, set the `g:filetype_md` var:

```
:let g:filetype_md = 'pandoc'
```

The pandoc syntax plugin uses `conceal` for pretty highlighting. Default is 1

```
:let g:pandoc#syntax#conceal#use = 1
```

To specify elements that should not be concealed, set the following variable:

```
:let g:pandoc#syntax#conceal#blacklist = []
```

This is a list of the rules which can be used here:

- titleblock

- image
- block
- subscript
- superscript
- strikeout
- atx
- codeblock\_start
- codeblock\_delim
- footnote
- definition
- list
- newline
- dashes
- ellipses
- quotes
- inlinecode
- inlinemath

You can customize the way concealing works. For example, if you prefer to mark footnotes with the `\*` symbol:

```
:let g:pandoc#syntax#conceal#cchar_overrides = {"footnote" : "*"}
```

To conceal the urls in links, use:

```
:let g:pandoc#syntax#conceal#urls = 1
```

Prevent highlighting specific codeblock types so that they remain Normal. Codeblock types include "definition" for codeblocks inside definition blocks and "delimited" for delimited codeblocks. Default = []

```
:let g:pandoc#syntax#codeblocks#ignore = ['definition']
```

Use embedded highlighting for delimited codeblocks where a language is specified. Default = 1

```
:let g:pandoc#syntax#codeblocks#embeds#use = 1
```

For specify what languages and using what syntax files to highlight embeds. This is a list of language names. When the language pandoc and vim use don't match, you can use the "PANDOC=VIM" syntax. For example:

```
:let g:pandoc#syntax#codeblocks#embeds#langs = ["ruby", "bash=sh"]
```

To use italics and strong in emphases. Default = 1

```
:let g:pandoc#syntax#style#emphases = 1
```

"0" will add "block" to g:pandoc#syntax#conceal#blacklist, because otherwise you couldn't tell where the styles are applied.

To add underline subscript, superscript and strikeout text styles. Default = 1

```
:let g:pandoc#syntax#style#underline_special = 1
```

Detect and highlight definition lists. Disabling this can improve performance. Default = 1 (i.e., enabled by default)

```
:let g:pandoc#syntax#style#use_definition_lists = 1
```

The pandoc syntax script also comes with the following commands:

```
:PandocHighlight LANG
```

Enables embedded highlighting for language LANG in codeblocks. Uses the syntax for items in g:pandoc#syntax#codeblocks#embeds#langs.

```
:PandocUnhighlight LANG
```

Disables embedded highlighting for language LANG in codeblocks.

**PAPP** papp.vim ft-papp-syntax

The PApp syntax file handles .papp files and, to a lesser extent, .pxml and .pxsl files which are all a mixture of perl/xml/html/other using xml as the top-level file format. By default everything inside phtml or pxml sections is treated as a string with embedded preprocessor commands. If you set the variable:

```
:let papp_include_html=1
```

in your startup file it will try to syntax-highlight html code inside phtml sections, but this is relatively slow and much too colourful to be able to edit sensibly. ;)

The newest version of the papp.vim syntax file can usually be found at <http://papp.plan9.de>.

**PASCAL** pascal.vim ft-pascal-syntax

Files matching "\*.p" could be Progress or Pascal and those matching "\*.pp" could be Puppet or Pascal. If the automatic detection doesn't work for you, or you only edit Pascal files, use this in your startup vimrc:

```
:let filetype_p = "pascal"
:let filetype_pp = "pascal"
```

The Pascal syntax file has been extended to take into account some extensions provided by Turbo Pascal, Free Pascal Compiler and GNU Pascal Compiler. Delphi keywords are also supported. By default, Turbo Pascal 7.0 features are enabled. If you prefer to stick with the standard Pascal keywords, add the following line to your startup file:

```
:let pascal_traditional=1
```

To switch on Delphi specific constructions (such as one-line comments, keywords, etc):

```
:let pascal_delphi=1
```

The option `pascal_symbol_operator` controls whether symbol operators such as `+`, `*`, `..`, etc. are displayed using the Operator color or not. To colorize symbol operators, add the following line to your startup file:

```
:let pascal_symbol_operator=1
```

Some functions are highlighted by default. To switch it off:

```
:let pascal_no_functions=1
```

Furthermore, there are specific variables for some compilers. Besides `pascal_delphi`, there are `pascal_gpc` and `pascal_fpc`. Default extensions try to match Turbo Pascal.

```
:let pascal_gpc=1
```

or

```
:let pascal_fpc=1
```

To ensure that strings are defined on a single line, you can define the `pascal_one_line_string` variable.

```
:let pascal_one_line_string=1
```

If you dislike `<Tab>` chars, you can set the `pascal_no_tabs` variable. Tabs will be highlighted as Error.

```
:let pascal_no_tabs=1
```

## PERL

`perl.vim` `ft-perl-syntax`

There are a number of possible options to the perl syntax highlighting.

Inline POD highlighting is now turned on by default. If you don't wish to have the added complexity of highlighting POD embedded within Perl files, you may set the `'perl_include_pod'` option to 0:

```
:let perl_include_pod = 0
```

To reduce the complexity of parsing (and increase performance) you can switch off two elements in the parsing of variable names and contents.

To handle package references in variable and function names not differently from the rest of the name (like `'PkgName::'` in `'$PkgName::VarName'`):

```
:let perl_no_scope_in_variables = 1
```

(In Vim 6.x it was the other way around: "perl\_want\_scope\_in\_variables" enabled it.)

If you do not want complex things like '@{\${"foo"}}' to be parsed:

```
:let perl_no_extended_vars = 1
```

(In Vim 6.x it was the other way around: "perl\_extended\_vars" enabled it.)

The coloring strings can be changed. By default strings and qq friends will be highlighted like the first line. If you set the variable perl\_string\_as\_statement, it will be highlighted as in the second line.

```
"hello world!"; qq|hello world|;
AAAAAAAAAAAAAAAA^NNAAAAAAAAAAAAAAAA^N (unlet perl_string_as_statement)
SAAAAAAAAAAAAAAAA^SNSSSAAAAAAAAAAAAAAAA^SN (let perl_string_as_statement)
```

(^ = perlString, S = perlStatement, N = None at all)

The syncing has 3 options. The first two switch off some triggering of synchronization and should only be needed in case it fails to work properly. If while scrolling all of a sudden the whole screen changes color completely then you should try and switch off one of those. Let the developer know if you can figure out the line that causes the mistake.

One triggers on "^\\s\*sub\\s\*" and the other on "^[\$@%]" more or less.

```
:let perl_no_sync_on_sub
:let perl_no_sync_on_global_var
```

Below you can set the maximum distance VIM should look for starting points for its attempts in syntax highlighting.

```
:let perl_sync_dist = 100
```

If you want to use folding with perl, set perl\_fold:

```
:let perl_fold = 1
```

If you want to fold blocks in if statements, etc. as well set the following:

```
:let perl_fold_blocks = 1
```

Subroutines are folded by default if 'perl\_fold' is set. If you do not want this, you can set 'perl\_nofold\_subs':

```
:let perl_nofold_subs = 1
```

Anonymous subroutines are not folded by default; you may enable their folding via 'perl\_fold\_anonymous\_subs':

```
:let perl_fold_anonymous_subs = 1
```

Packages are also folded by default if 'perl\_fold' is set. To disable this

behavior, set 'perl\_nofold\_packages':

```
:let perl_nofold_packages = 1
```

PHP3 and PHP4                    php.vim    php3.vim    ft-php-syntax    ft-php3-syntax

[Note: Previously this was called "php3", but since it now also supports php4 it has been renamed to "php"]

There are the following options for the php syntax highlighting.

If you like SQL syntax highlighting inside Strings:

```
let php_sql_query = 1
```

For highlighting the Baselib methods:

```
let php_baselib = 1
```

Enable HTML syntax highlighting inside strings:

```
let php_htmlInStrings = 1
```

Using the old colorstyle:

```
let php_oldStyle = 1
```

Enable highlighting ASP-style short tags:

```
let php_asp_tags = 1
```

Disable short tags:

```
let php_noShortTags = 1
```

For highlighting parent error ] or ):

```
let php_parent_error_close = 1
```

For skipping a php end tag, if there exists an open ( or [ without a closing one:

```
let php_parent_error_open = 1
```

Enable folding for classes and functions:

```
let php_folding = 1
```

Selecting syncing method:

```
let php_sync_method = x
```

x = -1 to sync by search (default),  
x > 0 to sync at least x lines backwards,

x = 0 to sync from start.

## **PLAINTEX** plaintex.vim ft-plaintex-syntax

TeX is a typesetting language, and plaintex is the file type for the "plain" variant of TeX. If you never want your \*.tex files recognized as plain TeX, see [ft-tex-plugin](#) .

This syntax file has the option

```
let g:plaintex_delimiters = 1
```

if you want to highlight brackets "[]" and braces "{}".

## **PPWIZARD** ppwiz.vim ft-ppwiz-syntax

PPWizard is a preprocessor for HTML and OS/2 INF files

This syntax file has the options:

- ppwiz\_highlight\_defs : Determines highlighting mode for PPWizard's definitions. Possible values are

ppwiz\_highlight\_defs = 1 : PPWizard #define statements retain the colors of their contents (e.g. PPWizard macros and variables).

ppwiz\_highlight\_defs = 2 : Preprocessor #define and #evaluate statements are shown in a single color with the exception of line continuation symbols.

The default setting for ppwiz\_highlight\_defs is 1.

- ppwiz\_with\_html : If the value is 1 (the default), highlight literal HTML code; if 0, treat HTML code like ordinary text.

## **PHTML** phtml.vim ft-phtml-syntax

There are two options for the phtml syntax highlighting.

If you like SQL syntax highlighting inside Strings, use this:

```
:let phtml_sql_query = 1
```

For syncing, minlines defaults to 100. If you prefer another value, you can set "phtml\_minlines" to the value you desire. Example:

```
:let phtml_minlines = 200
```

## **POSTSCRIPT** postscr.vim ft-postscr-syntax

There are several options when it comes to highlighting PostScript.

First which version of the PostScript language to highlight. There are currently three defined language versions, or levels. Level 1 is the original and base version, and includes all extensions prior to the release of level 2. Level 2 is the most common version around, and includes its own set of extensions prior to the release of level 3. Level 3 is currently the highest level supported. You select which level of the PostScript language you want highlighted by defining the `postscr_level` variable as follows:

```
:let postscr_level=2
```

If this variable is not defined it defaults to 2 (level 2) since this is the most prevalent version currently.

**Note:** Not all PS interpreters will support all language features for a particular language level. In particular the `%!PS-Adobe-3.0` at the start of PS files does NOT mean the PostScript present is level 3 PostScript!

If you are working with Display PostScript, you can include highlighting of Display PS language features by defining the `postscr_display` variable as follows:

```
:let postscr_display=1
```

If you are working with Ghostscript, you can include highlighting of Ghostscript specific language features by defining the variable `postscr_ghostscript` as follows:

```
:let postscr_ghostscript=1
```

PostScript is a large language, with many predefined elements. While it useful to have all these elements highlighted, on slower machines this can cause Vim to slow down. In an attempt to be machine friendly font names and character encodings are not highlighted by default. Unless you are working explicitly with either of these this should be ok. If you want them to be highlighted you should set one or both of the following variables:

```
:let postscr_fonts=1
:let postscr_encodings=1
```

There is a stylistic option to the highlighting of `and`, `or`, and `not`. In PostScript the function of these operators depends on the types of their operands - if the operands are booleans then they are the logical operators, if they are integers then they are binary operators. As binary and logical operators can be highlighted differently they have to be highlighted one way or the other. By default they are treated as logical operators. They can be highlighted as binary operators by defining the variable `postscr_andornot_binary` as follows:

```
:let postscr_andornot_binary=1
```

[ptcap.vim](#) [ft-printcap-syntax](#)

PRINTCAP + TERMCAP [ft-ptcap-syntax](#) [ft-termcap-syntax](#)

This syntax file applies to the printcap and termcap databases.

In order for Vim to recognize printcap/termcap files that do not match the patterns `*printcap*`, or `*termcap*`, you must put additional patterns appropriate to your system in your `myfiletypefile` file. For these patterns, you must set the variable `"b:ptcap_type"` to either `"print"` or `"term"`, and then the `'filetype'` option to `ptcap`.

For example, to make Vim identify all files in `/etc/termcaps/` as termcap files, add the following:

```
:au BufNewFile,BufRead /etc/termcaps/* let b:ptcap_type = "term" |
\ set filetype=ptcap
```

If you notice highlighting errors while scrolling backwards, which are fixed when redrawing with **CTRL-L**, try setting the `"ptcap_minlines"` internal variable to a larger number:

```
:let ptcap_minlines = 50
```

(The default is 20 lines.)

**PROGRESS** [progress.vim](#) [ft-progress-syntax](#)

Files matching `*.w` could be Progress or cweb. If the automatic detection doesn't work for you, or you don't edit cweb at all, use this in your startup vimrc:

```
:let filetype_w = "progress"
```

The same happens for `*.i`, which could be assembly, and `*.p`, which could be Pascal. Use this if you don't use assembly and Pascal:

```
:let filetype_i = "progress"
```

```
:let filetype_p = "progress"
```

**PYTHON** [python.vim](#) [ft-python-syntax](#)

There are six options to control Python syntax highlighting.

For highlighted numbers:

```
:let python_no_number_highlight = 1
```

For highlighted builtin functions:

```
:let python_no_builtin_highlight = 1
```

For highlighted standard exceptions:

```
:let python_no_exception_highlight = 1
```

For highlighted doctests and code inside:

```
:let python_no_doctest_highlight = 1
```

or

```
:let python_no_doctest_code_highlight = 1
```

The first option implies the second one.

For highlighted trailing whitespace and mix of spaces and tabs:

```
:let python_space_error_highlight = 1
```

If you want all possible Python highlighting:

```
:let python_highlight_all = 1
```

This has the same effect as setting `python_space_error_highlight` and unsetting all the other ones.

If you use Python 2 or straddling code (Python 2 and 3 compatible), you can enforce the use of an older syntax file with support for Python 2 and up to Python 3.5.

```
:let python_use_python2_syntax = 1
```

This option will exclude all modern Python 3.6 or higher features.

**Note:** Only existence of these options matters, not their value. You can replace 1 above with anything.

## QUAKE

`quake.vim` `ft-quake-syntax`

The Quake syntax definition should work for most FPS (First Person Shooter) based on one of the Quake engines. However, the command names vary a bit between the three games (Quake, Quake 2, and Quake 3 Arena) so the syntax definition checks for the existence of three global variables to allow users to specify what commands are legal in their files. The three variables can be set for the following effects:

set to highlight commands only available in Quake:

```
:let quake_is_quake1 = 1
```

set to highlight commands only available in Quake 2:

```
:let quake_is_quake2 = 1
```

set to highlight commands only available in Quake 3 Arena:

```
:let quake_is_quake3 = 1
```

Any combination of these three variables is legal, but might highlight more commands than are actually available to you by the game.

## R

`r.vim` `ft-r-syntax`

The parsing of R code for syntax highlight starts 40 lines backwards, but you can set a different value in your `vimrc`. Example:

```
let r_syntax_minlines = 60
```

You can also turn off syntax highlighting of R0xygen:

```
let r_syntax_hl_roxygen = 0
```

enable folding of code delimited by parentheses, square brackets and curly braces:

```
let r_syntax_folding = 1
```

and highlight as functions all keywords followed by an opening parenthesis:  
`let r_syntax_fun_pattern = 1`

## **R MARKDOWN** `rmd.vim` `ft-rmd-syntax`

To disable syntax highlight of YAML header, add to your `vimrc` :  
`let rmd_syn_hl_yaml = 0`

To disable syntax highlighting of citation keys:  
`let rmd_syn_hl_citations = 0`

To highlight R code in knitr chunk headers:  
`let rmd_syn_hl_chunk = 1`

By default, chunks of R code will be highlighted following the rules of R language. Moreover, whenever the buffer is saved, Vim scans the buffer and highlights other languages if they are present in new chunks. LaTeX code also is automatically recognized and highlighted when the buffer is saved. This behavior can be controlled with the variables ``rmd_dynamic_fenced_languages``, and ``rmd_include_latex`` whose valid values are:

```
let rmd_dynamic_fenced_languages = 0 " No autodetection of languages
let rmd_dynamic_fenced_languages = 1 " Autodetection of languages
let rmd_include_latex = 0 " Don't highlight LaTeX code
let rmd_include_latex = 1 " Autodetect LaTeX code
let rmd_include_latex = 2 " Always include LaTeX highlighting
```

If the value of ``rmd_dynamic_fenced_languages`` is 0, you still can set the list of languages whose chunks of code should be properly highlighted, as in the example:

```
let rmd_fenced_languages = ['r', 'python']
```

## **R RESTRUCTURED TEXT** `rrst.vim` `ft-rrst-syntax`

To highlight R code in knitr chunk headers, add to your `vimrc` :  
`let rrst_syn_hl_chunk = 1`

## **RASI** `rasi.vim` `ft-rasi-syntax`

Rasi stands for Rofi Advanced Style Information. It is used by the program rofi to style the rendering of the search window. The language is heavily inspired by CSS stylesheet. Files with the following extensions are recognized as rasi files: `.rasi`.

## **READLINE** `readline.vim` `ft-readline-syntax`

The readline library is primarily used by the BASH shell, which adds quite a few commands and options to the ones already available. To highlight these items as well you can add the following to your `vimrc` or just type it in the command line before loading a file with the readline syntax:

```
let readline_has_bash = 1
```

This will add highlighting for the commands that BASH (version 2.05a and later, and part earlier) adds.

## REGO rego.vim ft-rego-syntax

Rego is a query language developed by Styra. It is mostly used as a policy language for kubernetes, but can be applied to almost anything. Files with the following extensions are recognized as rego files: .rego.

## RESTRUCTURED TEXT rst.vim ft-rst-syntax

Syntax highlighting is enabled for code blocks within the document for a select number of file types. See `$VIMRUNTIME/syntax/rst.vim` for the default syntax list.

To set a user-defined list of code block syntax highlighting:

```
let rst_syntax_code_list = ['vim', 'lisp', ...]
```

To assign multiple code block types to a single syntax, define `'rst_syntax_code_list'` as a mapping:

```
let rst_syntax_code_list = {
 \ 'cpp': ['cpp', 'c++'],
 \ 'bash': ['bash', 'sh'],
 ...
\ }
```

To use color highlighting for emphasis text:

```
let rst_use_emphasis_colors = 1
```

To enable folding of sections:

```
let rst_fold_enabled = 1
```

**Note** that folding can cause performance issues on some platforms.

## REXX rexx.vim ft-rexx-syntax

If you notice highlighting errors while scrolling backwards, which are fixed when redrawing with **CTRL-L**, try setting the "rexx\_minlines" internal variable to a larger number:

```
:let rexx_minlines = 50
```

This will make the syntax synchronization start 50 lines before the first displayed line. The default value is 10. The disadvantage of using a larger number is that redrawing can become slow.

Vim tries to guess what type a ".r" file is. If it can't be detected (from comment lines), the default is "r". To make the default rexx add this line to your .vimrc: `g:filetype_r`

```
:let g:filetype_r = "r"
```

## RUBY

ruby.vim ft-ruby-syntax

Ruby: Operator highlighting	ruby_operators
Ruby: Whitespace errors	ruby_space_errors
Ruby: Folding	ruby_fold ruby_foldable_groups
Ruby: Reducing expensive operations	ruby_no_expensive ruby_minlines
Ruby: Spellchecking strings	ruby_spellcheck_strings

ruby\_operators

### Ruby: Operator highlighting

Operators can be highlighted by defining "ruby\_operators":

```
:let ruby_operators = 1
```

ruby\_space\_errors

### Ruby: Whitespace errors

Whitespace errors can be highlighted by defining "ruby\_space\_errors":

```
:let ruby_space_errors = 1
```

This will highlight trailing whitespace and tabs preceded by a space character as errors. This can be refined by defining "ruby\_no\_trail\_space\_error" and "ruby\_no\_tab\_space\_error" which will ignore trailing whitespace and tabs after spaces respectively.

ruby\_fold ruby\_foldable\_groups

### Ruby: Folding

Folding can be enabled by defining "ruby\_fold":

```
:let ruby_fold = 1
```

This will set the value of '**foldmethod**' to "syntax" locally to the current buffer or window, which will enable syntax-based folding when editing Ruby filetypes.

Default folding is rather detailed, i.e., small syntax units like "if", "do", "%w[]" may create corresponding fold levels.

You can set "ruby\_foldable\_groups" to restrict which groups are foldable:

```
:let ruby_foldable_groups = 'if case %'
```

The value is a space-separated list of keywords:

keyword	meaning
ALL	Most block syntax (default)
NONE	Nothing
if	"if" or "unless" block
def	"def" block

class	"class" block
module	"module" block
do	"do" block
begin	"begin" block
case	"case" block
for	"for", "while", "until" loops
{	Curly bracket block or hash literal
[	Array literal
%	Literal with "%" notation, e.g.: %w(String), %!STRING!
/	Regexp
string	String and shell command output (surrounded by ', ', `)
:	Symbol
#	Multiline comment
<<	Here documents
__END__	Source code after "__END__" directive

ruby\_no\_expensive

### Ruby: Reducing expensive operations

By default, the "end" keyword is colored according to the opening statement of the block it closes. While useful, this feature can be expensive; if you experience slow redrawing (or you are on a terminal with poor color support) you may want to turn it off by defining the "ruby\_no\_expensive" variable:

```
:let ruby_no_expensive = 1
```

In this case the same color will be used for all control keywords.

ruby\_minlines

If you do want this feature enabled, but notice highlighting errors while scrolling backwards, which are fixed when redrawing with **CTRL-L**, try setting the "ruby\_minlines" variable to a value larger than 50:

```
:let ruby_minlines = 100
```

Ideally, this value should be a number of lines large enough to embrace your largest class or module.

ruby\_spellcheck\_strings

### Ruby: Spellchecking strings

Ruby syntax will perform spellchecking of strings if you define "ruby\_spellcheck\_strings":

```
:let ruby_spellcheck_strings = 1
```

### SCHEME

scheme.vim ft-scheme-syntax

By default only R7RS keywords are highlighted and properly indented.

scheme.vim also supports extensions of the CHICKEN Scheme->C compiler. Define b:is\_chicken or g:is\_chicken, if you need them.

## SDL

[sdl.vim](#) [ft-sdl-syntax](#)

The SDL highlighting probably misses a few keywords, but SDL has so many of them it's almost impossible to cope.

The new standard, SDL-2000, specifies that all identifiers are case-sensitive (which was not so before), and that all keywords can be used either completely lowercase or completely uppercase. To have the highlighting reflect this, you can set the following variable:

```
:let sdl_2000=1
```

This also sets many new keywords. If you want to disable the old keywords, which is probably a good idea, use:

```
:let SDL_no_96=1
```

The indentation is probably also incomplete, but right now I am very satisfied with it for my own projects.

## SED

[sed.vim](#) [ft-sed-syntax](#)

To make tabs stand out from regular blanks (accomplished by using Todo highlighting on the tabs), define "g:sed\_highlight\_tabs" by putting

```
:let g:sed_highlight_tabs = 1
```

in the vimrc file. (This special highlighting only applies for tabs inside search patterns, replacement texts, addresses or text included by an Append/Change/Insert command.) If you enable this option, it is also a good idea to set the tab width to one character; by doing that, you can easily count the number of tabs in a string.

GNU sed allows comments after text on the same line. BSD sed only allows comments where "#" is the first character of the line. To enforce BSD-style comments, i.e. mark end-of-line comments as errors, use:

```
:let g:sed_dialect = "bsd"
```

**Note** that there are other differences between GNU sed and BSD sed which are not (yet) affected by this setting.

### Bugs:

The transform command (y) is treated exactly like the substitute command. This means that, as far as this syntax file is concerned, transform accepts the same flags as substitute, which is wrong. (Transform accepts no flags.) I tolerate this bug because the involved commands need very complex treatment (95 patterns, one for each plausible pattern delimiter).

## SGML

`sgml.vim` `ft-sgml-syntax`

The coloring scheme for tags in the SGML file works as follows.

The `<>` of opening tags are colored differently than the `</>` of a closing tag. This is on purpose! For opening tags the 'Function' color is used, while for closing tags the 'Type' color is used (See `syntax.vim` to check how those are defined for you)

Known tag names are colored the same way as statements in C. Unknown tag names are not colored which makes it easy to spot errors.

**Note** that the same is true for argument (or attribute) names. Known attribute names are colored differently than unknown ones.

Some SGML tags are used to change the rendering of text. The following tags are recognized by the `sgml.vim` syntax coloring file and change the way normal text is shown: `<varname>` `<emphasis>` `<command>` `<function>` `<literal>` `<replaceable>` `<ulink>` and `<link>`.

If you want to change how such text is rendered, you must redefine the following syntax groups:

- `sgmlBold`
- `sgmlBoldItalic`
- `sgmlUnderline`
- `sgmlItalic`
- `sgmlLink` for links

To make this redefinition work you must redefine them all and define the following variable in your `vimrc` (this is due to the order in which the files are read during initialization)

```
let sgml_my_rendering=1
```

You can also disable this rendering by adding the following line to your `vimrc` file:

```
let sgml_no_rendering=1
```

(Adapted from the `html.vim` help text by Claudio Fleiner [<claudio@fleiner.com>](mailto:claudio@fleiner.com))

**SH** `ft-posix-syntax` `ft-dash-syntax`  
`sh.vim` `ft-sh-syntax` `ft-bash-syntax` `ft-ksh-syntax`

This covers syntax highlighting for the older Unix (Bourne) `sh`, and newer shells such as `bash`, `dash`, `posix`, and the Korn shells.

Vim attempts to determine which shell type is in use by specifying that various filenames are of specific types, e.g.:

```
ksh : .kshrc* *.ksh
bash: .bashrc* bashrc bash.bashrc .bash_profile* *.bash
```

See `$(VIMRUNTIME)/filetype.vim` for the full list of patterns. If none of these

cases pertain, then the first line of the file is examined (ex. looking for /bin/sh /bin/ksh /bin/bash). If the first line specifies a shelltype, then that shelltype is used. However some files (ex. .profile) are known to be shell files but the type is not apparent. Furthermore, on many systems sh is symbolically linked to "bash" (Linux, Windows+cygwin) or "ksh" (Posix).

One may specify a global default by instantiating one of the following variables in your `<.vimrc>`:

```
ksh:
 let g:is_kornshell = 1
posix: (using this is nearly the same as setting g:is_kornshell to 1)
 let g:is_posix = 1
bash:
 let g:is_bash = 1
sh: (default) Bourne shell
 let g:is_sh = 1
```

(dash users should use posix)

If there's no "#! ..." line, and the user hasn't availed himself/herself of a default sh.vim syntax setting as just shown, then syntax/sh.vim will assume the Bourne shell syntax. No need to quote RFCs or market penetration statistics in error reports, please -- just select the default version of the sh your system uses and install the associated "let..." in your `<.vimrc>`.

The syntax/sh.vim file provides several levels of syntax-based folding:

```
let g:sh_fold_enabled= 0 (default, no syntax folding)
let g:sh_fold_enabled= 1 (enable function folding)
let g:sh_fold_enabled= 2 (enable heredoc folding)
let g:sh_fold_enabled= 4 (enable if/do/for folding)
```

then various syntax items (ie. HereDocuments and function bodies) become syntax-foldable (see `:syn-fold`). You also may add these together to get multiple types of folding:

```
let g:sh_fold_enabled= 3 (enables function and heredoc folding)
```

If you notice highlighting errors while scrolling backwards which are fixed when one redraws with **CTRL-L**, try setting the "sh\_minlines" internal variable to a larger number. Example:

```
let sh_minlines = 500
```

This will make syntax synchronization start 500 lines before the first displayed line. The default value is 200. The disadvantage of using a larger number is that redrawing can become slow.

If you don't have much to synchronize on, displaying can be very slow. To reduce this, the "sh\_maxlines" internal variable can be set. Example:

```
let sh_maxlines = 100
```

The default is to use the twice `sh_minlines`. Set it to a smaller number to speed up displaying. The disadvantage is that highlight errors may appear.

`syntax/sh.vim` tries to flag certain problems as errors; usually things like unmatched `"]`, `"done"`, `"fi"`, etc. If you find the error handling problematic for your purposes, you may suppress such error highlighting by putting the following line in your `.vimrc`:

```
let g:sh_no_error= 1
```

`sh-embed`    `sh-awk`

## Sh: EMBEDDING LANGUAGES

You may wish to embed languages into sh. I'll give an example courtesy of Lorance Stinson on how to do this with `awk` as an example. Put the following file into `$HOME/.vim/after/syntax/sh/awkembed.vim`:

```
" AWK Embedding:
" =====
" Shamelessly ripped from asperl.vim by Aaron Hope.
if exists("b:current_syntax")
 unlet b:current_syntax
endif
syn include @AWKScript syntax/awk.vim
syn region AWKScriptCode matchgroup=AWKCommand start+=[\@<!' + skip+=\\'+ end=+' + c
syn region AWKScriptEmbedded matchgroup=AWKCommand start+=\<awk\>+ skip+=\\$+ end+=[\
syn cluster shCommandSubList add=AWKScriptEmbedded
hi def link AWKCommand Type
```

This code will then let the `awk` code in the single quotes:

```
awk '...awk code here...'
```

be highlighted using the `awk` highlighting syntax. Clearly this may be extended to other languages.

## SPEEDUP

`spup.vim`    `ft-spup-syntax`

(AspenTech plant simulator)

The Speedup syntax file has some options:

- `strict_subsections` : If this variable is defined, only keywords for sections and subsections will be highlighted as statements but not other keywords (like `WITHIN` in the `OPERATION` section).
- `highlight_types` : Definition of this variable causes stream types like temperature or pressure to be highlighted as `Type`, not as a plain Identifier. Included are the types that are usually found in the `DECLARE` section; if you defined own types, you have to include them in the syntax file.
- `oneline_comments` : This value ranges from 1 to 3 and determines the highlighting of `#` style comments.

oneline\_comments = 1 : Allow normal Speedup code after an even number of #s.

oneline\_comments = 2 : Show code starting with the second # as error. This is the default setting.

oneline\_comments = 3 : Show the whole line as error if it contains more than one #.

Since especially OPERATION sections tend to become very large due to PRESETting variables, syncing may be critical. If your computer is fast enough, you can increase minlines and/or maxlines near the end of the syntax file.

## SQL

sql.vim ft-sql-syntax  
sqlinformix.vim ft-sqlinformix-syntax  
sqlanywhere.vim ft-sqlanywhere-syntax

While there is an ANSI standard for SQL, most database engines add their own custom extensions. Vim currently supports the Oracle and Informix dialects of SQL. Vim assumes "\*.sql" files are Oracle SQL by default.

Vim currently has SQL support for a variety of different vendors via syntax scripts. You can change Vim's default from Oracle to any of the current SQL supported types. You can also easily alter the SQL dialect being used on a buffer by buffer basis.

For more detailed instructions see [ft\\_sql.txt](#) .

## SQUIRREL

squirrel.vim ft-squirrel-syntax

Squirrel is a high level imperative, object-oriented programming language, designed to be a light-weight scripting language that fits in the size, memory bandwidth, and real-time requirements of applications like video games. Files with the following extensions are recognized as squirrel files: .nut.

## TCSH

tcsh.vim ft-tcsh-syntax

This covers the shell named "tcsh". It is a superset of csh. See [csh.vim](#) for how the filetype is detected.

Tcsh does not allow \" in strings unless the "backslash\_quote" shell variable is set. If you want VIM to assume that no backslash quote constructs exist add this line to your .vimrc:

```
:let tcsh_backslash_quote = 0
```

If you notice highlighting errors while scrolling backwards, which are fixed when redrawing with **CTRL-L**, try setting the "tcsh\_minlines" internal variable to a larger number:

```
:let tcsh_minlines = 1000
```

This will make the syntax synchronization start 1000 lines before the first displayed line. If you set "tcsh\_minlines" to "fromstart", then synchronization is done from the start of the file. The default value for tcsh\_minlines is 100. The disadvantage of using a larger number is that redrawing can become slow.

**TEX** `tex.vim` `ft-tex-syntax` `latex-syntax`  
`syntax-tex` `syntax-latex`

`tex-folding` `g:tex_fold_enabled`

Tex: Want Syntax Folding?

As of version 28 of `<syntax/tex.vim>`, syntax-based folding of parts, chapters, sections, subsections, etc are supported. Put

```
let g:tex_fold_enabled=1
```

in your `<.vimrc>`, and `:set fdm=syntax`. I suggest doing the latter via a modeline at the end of your LaTeX file:

```
% vim: fdm=syntax
```

If your system becomes too slow, then you might wish to look into

[https://vimhelp.org/vim\\_faq.txt.html#faq-29.7](https://vimhelp.org/vim_faq.txt.html#faq-29.7)

`g:tex_nospell`

Tex: No Spell Checking Wanted

If you don't want spell checking anywhere in your LaTeX document, put

```
let g:tex_nospell=1
```

into your `.vimrc`. If you merely wish to suppress spell checking inside comments only, see `g:tex_comment_nospell` .

`tex-nospell` `g:tex_comment_nospell`

Tex: Don't Want Spell Checking In Comments?

Some folks like to include things like source code in comments and so would prefer that spell checking be disabled in comments in LaTeX files. To do

this, put the following in your `<.vimrc>`:

```
let g:tex_comment_nospell= 1
```

If you want to suppress spell checking everywhere inside your LaTeX document, see `g:tex_nospell` .

```
tex-verb g:tex_verbspell
```

Tex: Want Spell Checking in Verbatim Zones?

Often verbatim regions are used for things like source code; seldom does one want source code spell-checked. However, for those of you who do want your verbatim zones spell-checked, put the following in your `<.vimrc>`:

```
let g:tex_verbspell= 1
```

```
tex-runon tex-stopzone
```

Tex: Run-on Comments or MathZones

The `<syntax/tex.vim>` highlighting supports TeX, LaTeX, and some AmsTeX. The highlighting supports three primary zones/regions: normal, texZone, and texMathZone. Although considerable effort has been made to have these zones terminate properly, zones delineated by `$.$.` and `$$$. $$` cannot be synchronized as there's no difference between start and end patterns. Consequently, a special "TeX comment" has been provided

```
%stopzone
```

which will forcibly terminate the highlighting of either a texZone or a texMathZone.

```
tex-slow tex-sync
```

Tex: Slow Syntax Highlighting?

If you have a slow computer, you may wish to reduce the values for

```
:syn sync maxlines=200
```

```
:syn sync minlines=50
```

(especially the latter). If your computer is fast, you may wish to increase them. This primarily affects synchronizing (i.e. just what group, if any, is the text at the top of the screen supposed to be in?).

Another cause of slow highlighting is due to syntax-driven folding; see `tex-folding` for a way around this.

```
g:tex_fast
```

Finally, if syntax highlighting is still too slow, you may set

```
:let g:tex_fast= ""
```

in your `.vimrc`. Used this way, the `g:tex_fast` variable causes the syntax highlighting script to avoid defining any regions and associated synchronization. The result will be much faster syntax highlighting; the price: you will no longer have as much highlighting or any syntax-based folding, and you will be missing syntax-based error checking.

You may decide that some syntax is acceptable; you may use the following table selectively to enable just some syntax highlighting:

```
b : allow bold and italic syntax
c : allow texComment syntax
m : allow texMatcher syntax (ie. {...} and [...])
M : allow texMath syntax
p : allow parts, chapter, section, etc syntax
r : allow texRefZone syntax (nocite, bibliography, label, pageref, eqref)
s : allow superscript/subscript regions
S : allow texStyle syntax
v : allow verbatim syntax
V : allow texNewEnv and texNewCmd syntax
```

As an example, let `g:tex_fast="M"` will allow math-associated highlighting but suppress all the other region-based syntax highlighting.  
(also see: `g:tex_conceal` and `tex-supersub` )

`tex-morecommands`   `tex-package`

### Tex: Want To Highlight More Commands?

LaTeX is a programmable language, and so there are thousands of packages full of specialized LaTeX commands, syntax, and fonts. If you're using such a package you'll often wish that the distributed `syntax/tex.vim` would support it. However, clearly this is impractical. So please consider using the techniques in `mysyntaxfile-add` to extend or modify the highlighting provided by `syntax/tex.vim`. Please consider uploading any extensions that you write, which typically would go in `$HOME/after/syntax/tex/[pkgname].vim`, to <http://vim.sf.net/>.

I've included some support for various popular packages on my website:

<http://www.drchip.org/astronaut/vim/index.html#LATEXPKGS>

The syntax files there go into your `.../after/syntax/tex/` directory.

`tex-error`   `g:tex_no_error`

### Tex: Excessive Error Highlighting?

The `<tex.vim>` supports lexical error checking of various sorts. Thus, although the error checking is oftentimes very useful, it can indicate errors where none actually are. If this proves to be a problem for you, you may put in your `<.vimrc>` the following statement:

```
let g:tex_no_error=1
```

and all error checking by `<syntax/tex.vim>` will be suppressed.

`tex-math`

### Tex: Need a new Math Group?

If you want to include a new math group in your LaTeX, the following code shows you an example as to how you might do so:

```
call TexNewMathZone(sfx,mathzone,starform)
```

You'll want to provide the new math group with a unique suffix (currently, A-L and V-Z are taken by `<syntax/tex.vim>` itself).

As an example, consider how `eqnarray` is set up by `<syntax/tex.vim>`:

```
call TexNewMathZone("D","eqnarray",1)
```

You'll need to change "mathzone" to the name of your new math group,

and then to the call to it in `.vim/after/syntax/tex.vim`.  
The "starform" variable, if true, implies that your new math group has a starred form (ie. `eqnarray*`).

`tex-style`    `b:tex_stylish`

### Tex: Starting a New Style?

One may use `"\makeatletter"` in `*.tex` files, thereby making the use of "@" in commands available. However, since the `*.tex` file doesn't have one of the following suffices: `sty` `cls` `clo` `dtx` `ltx`, the syntax highlighting will flag such use of @ as an error. To solve this:

```
:let b:tex_stylish = 1
:set ft=tex
```

Putting `"let g:tex_stylish=1"` into your `<.vimrc>` will make `<syntax/tex.vim>` always accept such use of @.

`tex-cchar`    `tex-cole`    `tex-conceal`

### Tex: Taking Advantage of Conceal Mode

If you have `'conceallevel'` set to 2 and if your encoding is utf-8, then a number of character sequences can be translated into appropriate utf-8 glyphs, including various accented characters, Greek characters in MathZones, and superscripts and subscripts in MathZones. Not all characters can be made into superscripts or subscripts; the constraint is due to what utf-8 supports. In fact, only a few characters are supported as subscripts.

One way to use this is to have vertically split windows (see `CTRL-W_v`); one with `'conceallevel'` at 0 and the other at 2; and both using `'scrollbind'`.

`g:tex_conceal`

### Tex: Selective Conceal Mode

You may selectively use conceal mode by setting `g:tex_conceal` in your `<.vimrc>`. By default, `g:tex_conceal` is set to "admgs" to enable concealment for the following sets of characters:

```
a = accents/ligatures
b = bold and italic
d = delimiters
m = math symbols
g = Greek
s = superscripts/subscripts
```

By leaving one or more of these out, the associated conceal-character substitution will not be made.

`g:tex_isk`    `g:tex_stylish`

### Tex: Controlling iskeyword

Normally, LaTeX keywords support 0-9, a-z, A-z, and 192-255 only. Latex keywords don't support the underscore - except when in `*.sty` files. The syntax highlighting script handles this with the following logic:

- \* If `g:tex_stylish` exists and is 1
  - then the file will be treated as a "sty" file, so the "\_" will be allowed as part of keywords (regardless of `g:tex_isk`)
- \* Else if the file's suffix is `sty`, `cls`, `clo`, `dtx`, or `ltx`,
  - then the file will be treated as a "sty" file, so the "\_" will be allowed as part of keywords (regardless of `g:tex_isk`)
- \* If `g:tex_isk` exists, then it will be used for the local **'iskeyword'**
- \* Else the local **'iskeyword'** will be set to 48-57,a-z,A-Z,192-255

### `tex-supersub`   `g:tex_superscripts`   `g:tex_subscripts`

#### Tex: Fine Subscript and Superscript Control

See `tex-conceal` for how to enable concealed character replacement.

See `g:tex_conceal` for selectively concealing accents, bold/italic, math, Greek, and superscripts/subscripts.

One may exert fine control over which superscripts and subscripts one wants syntax-based concealment for (see `:syn-cchar`). Since not all fonts support all characters, one may override the concealed-replacement lists; by default these lists are given by:

```
let g:tex_superscripts= "[0-9a-zA-W.,;+<>/()=]"
let g:tex_subscripts= "[0-9aehijklmnoprstuvx,+-/().]"
```

For example, I use Luxi Mono Bold; it doesn't support subscript characters for "hklmpst", so I put

```
let g:tex_subscripts= "[0-9aeijoruvx,+-/().]"
```

in `~/vim/ftplugin/tex/tex.vim` in order to avoid having inscrutable utf-8 glyphs appear.

### `tex-matchcheck`   `g:tex_matchcheck`

#### Tex: Match Check Control

Sometimes one actually wants mismatched parentheses, square braces, and or curly braces; for example, `\text{(1,10]}` is a range from but not including 1 to and including 10. This wish, of course, conflicts with the desire to provide delimiter mismatch detection. To accommodate these conflicting goals, `syntax/tex.vim` provides

```
g:tex_matchcheck = '[([]'
```

which is shown along with its default setting. So, if one doesn't want `[]` and `()` to be checked for mismatches, try using

```
let g:tex_matchcheck= '[{}]'
```

If you don't want matching to occur inside bold and italicized regions,

```
let g:tex_excludematcher= 1
```

will prevent the `texMatcher` group from being included in those regions.

TF

`tf.vim`   `ft-tf-syntax`

There is one option for the tf syntax highlighting.

For syncing, minlines defaults to 100. If you prefer another value, you can set "tf\_minlines" to the value you desire. Example:

```
:let tf_minlines = your choice
```

## TYPESCRIPT

```
typescript.vim ft-typescript-syntax
typescriptreact.vim ft-typescriptreact-syntax
```

There is one option to control the TypeScript syntax highlighting.

When this variable is set to 1, host-specific APIs such as `addEventListener`` are highlighted. To disable set it to zero in your `.vimrc`:

```
let g:typescript_host_keyword = 0
```

The default value is 1.

## TYPST

```
ft-typst-syntax
```

Typst files can embed syntax highlighting for other languages by setting the `g:typst_embedded_languages` variable. This variable is a list of language names whose syntax definitions will be included in Typst files. Example:

```
let g:typst_embedded_languages = ['python', 'r']
```

## VIM

```
vim.vim ft-vim-syntax
g:vimsyn_minlines g:vimsyn_maxlines
```

There is a trade-off between more accurate syntax highlighting versus screen updating speed. To improve accuracy, you may wish to increase the `g:vimsyn_minlines` variable. The `g:vimsyn_maxlines` variable may be used to improve screen updating rates (see `:syn-sync` for more on this).

```
g:vimsyn_minlines : used to set synchronization minlines
g:vimsyn_maxlines : used to set synchronization maxlines
```

(`g:vim_minlines` and `g:vim_maxlines` are deprecated variants of these two options)

The `g:vimsyn_embed` option allows users to select what, if any, types of embedded script highlighting they wish to have.

```
g:vimsyn_embed == 0 : don't support any embedded scripts
g:vimsyn_embed =~ 'l' : support embedded Lua
g:vimsyn_embed =~ 'm' : support embedded MzScheme
g:vimsyn_embed =~ 'p' : support embedded Perl
g:vimsyn_embed =~ 'P' : support embedded Python
g:vimsyn_embed =~ 'r' : support embedded Ruby
g:vimsyn_embed =~ 't' : support embedded Tcl
```

By default, `g:vimsyn_embed` is a string supporting interpreters that your vim itself supports. Concatenate the indicated characters to support multiple types of embedded interpreters (e.g., `g:vimsyn_embed = "mp"` supports embedded `mzscheme` and embedded `perl`).

`g:vimsyn_folding`

Some folding is now supported with when `'foldmethod'` is set to `"syntax"`:

```
g:vimsyn_folding == 0 or doesn't exist: no syntax-based folding
g:vimsyn_folding =~ 'a' : fold augroups
g:vimsyn_folding =~ 'c' : fold Vim9 classes
g:vimsyn_folding =~ 'e' : fold Vim9 enums
g:vimsyn_folding =~ 'f' : fold functions
g:vimsyn_folding =~ 'h' : fold heredocs
g:vimsyn_folding =~ 'i' : fold Vim9 interfaces
g:vimsyn_folding =~ 'H' : fold Vim9 legacy headers
g:vimsyn_folding =~ 'l' : fold Lua script
g:vimsyn_folding =~ 'm' : fold MzScheme script
g:vimsyn_folding =~ 'p' : fold Perl script
g:vimsyn_folding =~ 'P' : fold Python script
g:vimsyn_folding =~ 'r' : fold Ruby script
g:vimsyn_folding =~ 't' : fold Tcl script
```

By default, `g:vimsyn_folding` is unset. Concatenate the indicated characters to support folding of multiple syntax constructs (e.g., `g:vimsyn_folding = "fh"` will enable folding of both functions and heredocs).

`g:vimsyn_comment_strings`

By default, strings are highlighted inside comments. This may be disabled by setting `g:vimsyn_comment_strings` to `false`.

`g:vimsyn_noerror`

Not all error highlighting that `syntax/vim.vim` does may be correct; Vim script is a difficult language to highlight correctly. A way to suppress error highlighting is to put the following line in your `vimrc` :

```
let g:vimsyn_noerror = 1
```

To suppress only specific errors, define the following variables:

```
g:vimsyn_nobehaveerror = 1 " :behave error
g:vimsyn_vimFTError = 1 " :filetype error
g:vimsyn_noaugrouperor = 1 " :augroup error
g:vimsyn_noopererror = 1 " operator error
g:vimsyn_notypealiaserror = 1 " Vim9 type alias error
g:vimsyn_novimfunctionerror = 1 " Vim9 method error
g:vimsyn_nousercmderror = 1 " :com error
g:vimsyn_novimsynerror = 1 " :syn error
g:vimsyn_novimsyncaseerror = 1 " :syn case error
g:vimsyn_novimsynconcealerror = 1 " :syn conceal error
g:vimsyn_novimsynfoldlevelerror = 1 " :syn foldlevel error
g:vimsyn_novimsynspellerror = 1 " :syn spell error
g:vimsyn_novimsyncerror = 1 " :syn sync error
g:vimsyn_novimhictermerror = 1 " :hi error
```

```
g:vimsyn_vimhikeyerror = 1 " :hi key=arg error
```

To force highlighting of Neovim specific Vim script elements (even if not using Neovim), set

```
let g:vimsyn_vim_features = ['nvim']
```

## WDL

wdl.vim wdl-syntax

The Workflow Description Language is a way to specify data processing workflows with a human-readable and writeable syntax. This is used a lot in bioinformatics. More info on the spec can be found here:

<https://github.com/openwdl/wdl>

## XF86CONFIG

xf86conf.vim ft-xf86conf-syntax

The syntax of XF86Config file differs in XFree86 v3.x and v4.x. Both variants are supported. Automatic detection is used, but is far from perfect. You may need to specify the version manually. Set the variable `xf86conf_xfree86_version` to 3 or 4 according to your XFree86 version in your `.vimrc`. Example:

```
:let xf86conf_xfree86_version=3
```

When using a mix of versions, set the `b:xf86conf_xfree86_version` variable.

**Note** that spaces and underscores in option names are not supported. Use "SyncOnGreen" instead of "\_\_s yn con gr\_e\_e\_n" if you want the option name highlighted.

## XML

xml.vim ft-xml-syntax

Xml namespaces are highlighted by default. This can be inhibited by setting a global variable:

```
:let g:xml_namespace_transparent=1
```

xml-folding

The xml syntax file provides syntax `folding` (see `:syn-fold`) between start and end tags. This can be turned on by

```
:let g:xml_syntax_folding = 1
:set foldmethod=syntax
```

**Note:** Syntax folding might slow down syntax highlighting significantly, especially for large files.

## X Pixmaps (XPM)

xpm.vim ft-xpm-syntax

xpm.vim creates its syntax items dynamically based upon the contents of the XPM file. Thus if you make changes e.g. in the color specification strings, you have to source it again e.g. with `":set syn=xpm"`.

To copy a pixel with one of the colors, yank a "pixel" with "yl" and insert it somewhere else with "P".

Do you want to draw with the mouse? Try the following:

```
:function! GetPixel()
: let c = getline(".")[col(".") - 1]
: echo c
: exe "noremap <LeftMouse> <LeftMouse>r" .. c
: exe "noremap <LeftDrag> <LeftMouse>r" .. c
:endfunction
:noremap <RightMouse> <LeftMouse>:call GetPixel()<CR>
:set guicursor=n:hor20 " to see the color beneath the cursor
```

This turns the right button into a pipette and the left button into a pen. It will work with XPM files that have one character per pixel only and you must not click outside of the pixel strings, but feel free to improve it.

It will look much better with a font in a quadratic cell size, e.g. for X:

```
:set guifont=--*-clean-medium-r-*-*8-*-*-*-*80-*
```

## YAML

yaml.vim ft-yaml-syntax

g:yaml\_schema b:yaml\_schema

A YAML schema is a combination of a set of tags and a mechanism for resolving non-specific tags. For user this means that YAML parser may, depending on plain scalar contents, treat plain scalar (which can actually be only string and nothing else) as a value of the other type: null, boolean, floating-point, integer. `g:yaml\_schema` option determines according to which schema values will be highlighted specially. Supported schemas are

Schema	Description
failsafe	No additional highlighting.
json	Supports JSON-style numbers, booleans and null.
core	Supports more number, boolean and null styles.
pyyaml	In addition to core schema supports highlighting timestamps, but there are some differences in what is recognized as numbers and many additional boolean values not present in core schema.

Default schema is `core`.

**Note** that schemas are not actually limited to plain scalars, but this is the only difference between schemas defined in YAML specification and the only difference defined in the syntax file.

## ZSH

zsh.vim ft-zsh-syntax

The syntax script for zsh allows for syntax-based folding:

```
:let g:zsh_fold_enable = 1
```

=====

## 6. Defining a syntax

`:syn-define` E410

Vim understands three types of syntax items:

### 1. Keyword

It can only contain keyword characters, according to the characters specified with `:syn-iskeyword` or the `'iskeyword'` option. It cannot contain other syntax items. It will only match with a complete word (there are no keyword characters before or after the match). The keyword "if" would match in "if(a=b)", but not in "ifdef x", because "(" is not a keyword character and "d" is.

### 2. Match

This is a match with a single regexp pattern.

### 3. Region

This starts at a match of the "start" regexp pattern and ends with a match with the "end" regexp pattern. Any other text can appear in between. A "skip" regexp pattern can be used to avoid matching the "end" pattern.

Several syntax ITEMS can be put into one syntax GROUP. For a syntax group you can give highlighting attributes. For example, you could have an item to define a `"/ * .. */` comment and another one that defines a `"// .."` comment, and put them both in the "Comment" group. You can then specify that a "Comment" will be in bold font and have a blue color. You are free to make one highlight group for one syntax item, or put all items into one group. This depends on how you want to specify your highlighting attributes. Putting each item in its own group results in having to specify the highlighting for a lot of groups.

**Note** that a syntax group and a highlight group are similar. For a highlight group you will have given highlight attributes. These attributes will be used for the syntax group with the same name.

In case more than one item matches at the same position, the one that was defined LAST wins. Thus you can override previously defined syntax items by using an item that matches the same text. But a keyword always goes before a match or region. And a keyword with matching case always goes before a keyword with ignoring case.

## **PRIORITY**

`:syn-priority`

When several syntax items may match, these rules are used:

1. When multiple Match or Region items start in the same position, the item defined last has priority.
2. A Keyword has priority over Match and Region items.
3. An item that starts in an earlier position has priority over items that start in later positions.

## **DEFINING CASE**

`:syn-case` E390

`:sy[ntax] case [match | ignore]`  
This defines if the following `":syntax"` commands will work with matching case, when using "match", or with ignoring case, when using "ignore". **Note** that any items before this are not affected, and all items until the next `":syntax case"` command are affected.

`:sy[ntax] case`  
Show either "syntax case match" or "syntax case ignore".

## DEFINING FOLDLEVEL

`:syn-foldlevel`

`:sy[ntax] foldlevel start`  
`:sy[ntax] foldlevel minimum`  
This defines how the foldlevel of a line is computed when using `foldmethod=syntax` (see [fold-syntax](#) and `:syn-fold`):

`start:`            Use level of item containing start of line.  
`minimum:`        Use lowest local-minimum level of items on line.

The default is "start". Use "minimum" to search a line horizontally for the lowest level contained on the line that is followed by a higher level. This produces more natural folds when syntax items may close and open horizontally within a line.

`:sy[ntax] foldlevel`  
Show the current foldlevel method, either "syntax foldlevel start" or "syntax foldlevel minimum".

{not meaningful when Vim was compiled without `|+folding|` feature}

## SPELL CHECKING

`:syn-spell`

`:sy[ntax] spell toplevel`  
`:sy[ntax] spell notoplevel`  
`:sy[ntax] spell default`  
This defines where spell checking is to be done for text that is not in a syntax item:

`toplevel:`        Text is spell checked.  
`notoplevel:`     Text is not spell checked.  
`default:`        When there is a `@Spell` cluster no spell checking.

For text in syntax items use the `@Spell` and `@NoSpell` clusters [spell-syntax](#). When there is no `@Spell` and no `@NoSpell` cluster then spell checking is done for "default" and "toplevel".

To activate spell checking the **'spell'** option must be set.

`:sy[ntax] spell`  
Show the current syntax spell checking method, either "syntax spell toplevel", "syntax spell notoplevel" or "syntax spell default".

## SYNTAX ISKEYWORD SETTING

`:syn-iskeyword`

`:sy[ntax] iskeyword [clear | {option}]`

This defines the keyword characters. It's like the `'iskeyword'` option for but only applies to syntax highlighting.

`clear:` Syntax specific iskeyword setting is disabled and the buffer-local `'iskeyword'` setting is used.  
`{option}` Set the syntax `'iskeyword'` option to a new value.

Example:

```
:syntax iskeyword @,48-57,192-255,$,_
```

This would set the syntax specific iskeyword option to include all alphabetic characters, plus the numeric characters, all accented characters and also includes the `"_"` and the `"$"`.

If no argument is given, the current value will be output.

Setting this option influences what `/\k` matches in syntax patterns and also determines where `:syn-keyword` will be checked for a new match.

It is recommended when writing syntax files, to use this command to set the correct value for the specific syntax language and not change the `'iskeyword'` option.

## DEFINING KEYWORDS

`:syn-keyword`

`:sy[ntax] keyword {group-name} [{options}] {keyword} .. [{options}]`

This defines a number of keywords.

`{group-name}` Is a syntax group name such as "Comment".  
`[{options}]` See `:syn-arguments` below.  
`{keyword} ..` Is a list of keywords which are part of this group.

Example:

```
:syntax keyword Type int long char
```

The `{options}` can be given anywhere in the line. They will apply to all keywords given, also for options that come after a keyword.

These examples do exactly the same:

```
:syntax keyword Type contained int long char
:syntax keyword Type int long contained char
:syntax keyword Type int long char contained
```

`E789` `E890`

When you have a keyword with an optional tail, like Ex commands in Vim, you can put the optional characters inside `[]`, to define all the variations at once:

```
:syntax keyword vimCommand ab[breviate] n[ext]
```

Don't forget that a keyword can only be recognized if all the characters are included in the `'iskeyword'` option. If one character

isn't, the keyword will never be recognized. Multi-byte characters can also be used. These do not have to be in **'iskeyword'**. See `:syn-iskeyword` for defining syntax specific iskeyword settings.

A keyword always has higher priority than a match or region, the keyword is used if more than one item matches. Keywords do not nest and a keyword can't contain anything else.

**Note** that when you have a keyword that is the same as an option (even one that isn't allowed here), you can not use it. Use a match instead.

The maximum length of a keyword is 80 characters.

The same keyword can be defined multiple times, when its containment differs. For example, you can define the keyword once not contained and use one highlight group, and once contained, and use a different highlight group. Example:

```
:syn keyword vimCommand tag
```

```
:syn keyword vimSetting contained tag
```

When finding "tag" outside of any syntax item, the "vimCommand" highlight group is used. When finding "tag" in a syntax item that contains "vimSetting", the "vimSetting" group is used.

## DEFINING MATCHES

`:syn-match`

```
:sy[ntax] match {group-name} [{options}]
 [excludenl]
 [keepend]
 {pattern}
 [{options}]
```

This defines one match.

`{group-name}`  
`[{options}]`  
`[excludenl]`

A syntax group name such as "Comment". See `:syn-arguments` below.

Don't make a pattern with the end-of-line "\$" extend a containing match or region. Must be given before the pattern. See `:syn-excludenl`

`keepend`

Don't allow contained matches to go past a match with the end pattern. See `:syn-keepend`.

`{pattern}`

The search pattern that defines the match. See `:syn-pattern` below.

**Note** that the pattern may match more than one line, which makes the match depend on where Vim starts searching for the pattern. You need to make sure syncing takes care of this.

Example (match a character constant):

```
:syntax match Character /\.'.'/hs=s+1,he=e-1
```

## DEFINING REGIONS

[:syn-region](#)    [:syn-start](#)    [:syn-skip](#)    [:syn-end](#)  
E398            E399

```
:sy[ntax] region {group-name} [{options}]
 [matchgroup={group-name}]
 [keepend]
 [extend]
 [excludenl]
 start={start-pattern} ..
 [skip={skip-pattern}]
 end={end-pattern} ..
 [{options}]
```

This defines one region. It may span several lines.

<a href="#">{group-name}</a>	A syntax group name such as "Comment".
<a href="#">[{options}]</a>	See <a href="#">:syn-arguments</a> below.
<a href="#">[matchgroup={group-name}]</a>	The syntax group to use for the following start or end pattern matches only. Not used for the text in between the matched start and end patterns. Use NONE to reset to not using a different group for the start or end match. See <a href="#">:syn-matchgroup</a> .
<a href="#">keepend</a>	Don't allow contained matches to go past a match with the end pattern. See <a href="#">:syn-keepend</a> .
<a href="#">extend</a>	Override a "keepend" for an item this region is contained in. See <a href="#">:syn-extend</a> .
<a href="#">excludenl</a>	Don't make a pattern with the end-of-line "\$" extend a containing match or item. Only useful for end patterns. Must be given before the patterns it applies to. <a href="#">:syn-excludenl</a>
<a href="#">start={start-pattern}</a>	The search pattern that defines the start of the region. See <a href="#">:syn-pattern</a> below.
<a href="#">skip={skip-pattern}</a>	The search pattern that defines text inside the region where not to look for the end pattern. See <a href="#">:syn-pattern</a> below.
<a href="#">end={end-pattern}</a>	The search pattern that defines the end of the region. See <a href="#">:syn-pattern</a> below.

Example:

```
:syntax region String start=+++ skip=+\\\"+ end=+++
```
